rents. These do not, however, result if only respiration with the aid of the pulmotor is induced. These researches show that, in case of clinical cardiac standstill, the chief value attaches to energetic heart massage. The stimulation of respiration alone does not suffice, since that in itself is inadequate for the stimulation of the heart. If the electrocardiograph gives evidence of cardiac standstill, there is no maneuver that will restore the circulation, nor will any injection exert such influence. Nevertheless, coincident with heart massage, artificial respiration must be applied in order that, after restoration of heart action, blood containing a normal amount of oxygen may be supplied to the heart muscle. Hence in cardiac and respiratory standstill, that is in apparent death, only such methods of artificial respiration are useful that permit in addition an energetic heart massage through somewhat vigorous thumping of the heart region.

Proposed Differentiation of University Professors

Some time ago Prof. Giacinto Bosco suggested that, after university professors have occupied a chair a certain number of years they be promoted to a higher rank. Recently Professor Taddei of Florence called attention to the difference in the preparation and the activities of a professor whose teaching is solely *ex cathedra* and the work of the professor whose duties include the active demonstration of fundamental principles. The surgeon, for example, is not ready to occupy a chair until he is at least 45 years of age, and he cannot ordinarily be a good demonstrator of surgical technic after he has passed the age of 70. On the other hand, a professor of law, of pure science or of languages may be a fairly good instructor at 28 and may continue to teach at the age of 75. Hence it is desirable, in the event of any reforms introduced in university professorships, that a distinction be made, from the standpoint both of salary and of morale, between professors of theoretical subjects and those who must combine active demonstration with instruction *ex cathedra*. The latter professorships require at least ten years more of preparation than the former and cannot be conscientiously held, by reason of diminished physical efficiency, up to the present age limit of 75, which is too high for such subjects.

Tuberculosis and Pregnancy

From controlled investigations carried out several years after childbirth (or miscarriage) on 105 tuberculous gravidas examined during the period 1925-1932 in the school of obstetrics and the maternity institute of Trieste, Dr. Duca emphasized that it is impossible to question the unfavorable influence of maternity on the pulmonary types of the first Neumann group, namely, in the destructive types with bronchogenic diffusion. Eighty-five per cent of such deaths occurred within a year from the termination of the pregnancy, whether at term, prematurely or the result of miscarriage.

The tuberculous types of the third group reveal only exceptionally an unfavorable action due to maternity. Maternity may reactivate also the rudimentary types, but the exacerbation does not last long and shows no tendency to develop further. In such cases there are seldom any indications for the interruption of pregnancy. Such intervention may, however, be useful, and even necessary, in well established cases of pulmonary disorders of the second group (types that develop by the hematogenic route) although, from the statistics of Dr. Duca, it appears that 75 per cent of the patients did not suffer any exacerbation imputable to the functions of maternity. The rare indications for therapeutic abortion in the types of the second group may in all probability be overlooked if the patients can be placed in a sanatorium during pregnancy and for a long period after confinement.

Prof Guglielmo Bilancioni

The death of Prof Guglielmo Bilancioni, director of the Clinica otorinolaringoiatrica of the University of Rome, at the age of 53, has been announced. He graduated at the University of Rome in 1905 and early acquired the *venia legendi* in general pathology and the history of medicine. He became professor at the University of Pisa in 1924 and removed to Rome in 1929, where he organized a large clinic, a much frequented ambulatorium (more than 20 000 patients annually) and laboratories for research. He was the author of 300 publications, among which were several books and a manual of his specialty in three volumes. Recently he had been engaged in the compilation of a work entitled "Laringe e polmone," which remains unfinished. His research includes studies on the musculature of the eustachian tube and its relations to the middle ear, explanations of the phenomena elicited by stimulation of the labyrinth and of their relations to the neurovegetative constitution of the individual, and studies on the changes in the blood vessels and in respiration during the rotatory movements of the body, on the manifestations of laryngeal fatigue, and on the local treatment of ozena. He was president of the Istituto storico italiano dell'arte sanitaria, founder of the monthly review *Il Val salva* and a member of the national commission for scientific vindications and of numerous Italian and foreign societies and academies. During the World War he contributed to the creation of laboratories for medical research on aeronautics and was consultant in otology in military aviation.

Course in Medicine Pertaining to Sport

The Federazione dei medici sportivi has organized a course in medicine pertaining to sport, which will be given at Rome. The first lecture was delivered by Professor Busi, dean of the faculty of medicine of the university, on the importance for sport devotees of the radiographic record of the thorax. To demonstrate the value of serial radiologic thoracic researches on sport devotees, the speaker passed rapidly in review the principles that today are dominant with respect to the pathogenesis of pulmonary tuberculosis, and he emphasized that it is necessary to search diligently for foci of pulmonary tuberculosis in young persons who are planning to devote themselves to sports. In Italy the view that sports should be organized on a hygienic and scientific basis is gaining adherents. During the past three years, Busi has been carrying on a prolonged experiment with radiographic thoracic record cards which consists in making serial observations on students of the faculty of medicine. The results thus far secured reveal that about 30 per cent of young persons who appear perfectly healthy have latent tuberculous foci in the respiratory apparatus.

Appointment of Four Health Inspectors for the Army

Recent legislation provides for the appointment of four health inspectors for the army. They will be under the control of the higher officers of the medical corps and will have charge of the health inspection service in its relation to the various armed forces. The inspectors will be located in Turin, Verona, Rome and Naples.

Radiologic Society

The south central group of the Società italiana di radiologia medica held recently its twentieth session in Naples, under the chairmanship of Professor Piccinino. Prof Antonio D'Istria discussed postoperative irradiation of mammary cancer. He stated that the current of opinion favorable to the use of postoperative roentgenotherapy has been gradually rising. Statistics revealed a frank improvement in the remote results in patients irradiated after the intervention in comparison with patients who have received no after-treatment. The speaker made an inquiry among the radiologic schools of the world, the greater part of which expressed themselves favorable to the systematic

application of the method. A few schools stated that they were decidedly opposed to systematic irradiation after surgical intervention and that they preferred to await a recurrence before applying irradiation.

Basing his opinion on replies to his questionnaire and on his personal experience, the speaker concluded that postoperative roentgenotherapy is to be regarded as surely effective. There were many communications presented on the subject.

Sorrentino gave a complete discussion of irradiation of the sinus caroticus, which he stimulated, either with diathermy or with roentgen rays, in healthy persons and in persons with high or low blood pressure. Contrary to the general opinion, he found that the results are slight and not of any practical value.

Milone emphasized the value of radiologic observations following gastro-enterostomy and explained his operative technique which he had been applying the past year with good results.

Two communications dealt with the subject of the azygos lobe, one being presented by Fucci of Naples, who carried out painstaking research on a lung with four lobes injecting into the various bronchi opaque substances, and reaching the conclusion that the azygos lobe is not an anatomic individuality.

AUSTRALIA

(From Our Regular Correspondent)

April 3, 1935

Royal Australasian College of Surgeons

An epoch of medical progress in Australia was marked March 4 when the building of the Royal Australasian College of Surgeons was formally opened in Melbourne by Sir Holburt Waring Bart., president of the Royal College of Surgeons of England, in the presence of a large gathering of physicians from many parts of the world. Every state in the commonwealth was represented as was the dominion of New Zealand, and representatives were present from the United Kingdom, from Canada, from South Africa, and from the United States of America. A special message to the college was sent by the king, and Sir Holburt Waring delivered a greeting from the council of the Royal College of Surgeons of England. Dr Henry Wade read a message from the council of the Royal College of Surgeons of Edinburgh. Dr Donald C. Bal four represented the American College of Surgeons and conveyed its greetings, and Prof. E. W. Archibald delivered a message from the Royal College of Surgeons of Canada.

Prof. F. Wood Jones of Melbourne delivered the Syrie oration for 1935 choosing as his title "The Master Surgeon." The period of the master surgeon lay between the years 1550 and 1850. Even if this period was not that in which surgery attained its greatest heights, it at least produced the greatest master surgeons. Professor Wood Jones spoke of the dexterity and skill of these men, of their love of humanity and of their tireless energy and capacity for work. He pointed out that the master surgeons were all master anatomists—they made anatomy a lifelong study and continued throughout their active lives to dissect and operate on the cadaver. They had an intense dislike to the performance of operations to operate on the human body was something to be done almost as a confession of failure. Turning to antiseptic and modern aseptic surgery, with its safe and comfortable anesthesia, Professor Wood Jones said that operations were nowadays so easy and might be undertaken with such impunity that many medical graduates muddled along in safety. He had a dream, admittedly an academic one, that the day of the master surgeon might dawn again, that surgeons would strive to emulate the master surgeon of olden days, and that all save emergency operations would be performed by a master hand. He expressed the opinion that clinical teachers should continually search for students who showed promise of developing the qualities of

the master surgeon and that every effort should be made to help such students and to train them in the science and art of surgery

The new building is an architectural ornament to Melbourne, a city already renowned for the dignity of its buildings. It is situated in park lands in near relationship to the state parliament house and the treasury buildings. In the design of the College of Surgeons building the architects have succeeded in evolving an edifice which is fresh and modern in spirit yet does not break with tradition. The main interest of the façade is the portico, with its flight of black steps. The pediment is carved with the coat of arms and the motto of the college and is supported by lofty square columns of Sydney sandstone. Over each entrance door is a plaque symbolic of various branches of the Royal College of Surgeons. Over the left-hand door a black swan represents the Western Australian branch, the center, the lion of Great Britain, the parent body, and the right the galleon representing the New Zealand branch. These pieces of ornament are burned in full color in terracotta. The tall entrance doors are bronze and plate glass and emphasize the verticality and dignity of the portico. Spaced at points of importance round the building are four niches which it is intended to furnish with busts, and at each end of the building are stone plaques in which full size statues can be placed. It is to be hoped that some generous citizen may make it possible to represent here those two benefactors to mankind Pasteur and Lister.

The building is the first step in a three stage project, which will ultimately include the provision of research facilities. In the field of modern medical architecture it is a fitting successor to the Institute of Anatomy at Canberra—a building that is at once arresting and inspiring.

Lead Poisoning at Smelters in Queensland

In the report of a medical study into the incidence of lead poisoning at the smelting works at Mount Isa, Queensland, an analysis of the claims for compensation for lead poisoning shows that the mine is responsible for 18.5 per cent of the total claims, the mill for 14.8 per cent, and the smelting works for 66.7 per cent, in other words, the smelters cause twice as much lead poisoning as the mine and the mill put together.

Routine examinations, including a careful blood investigation, were made of the 1,892 employees at the mine, and 27 per cent showed some slight or mild degree of lead poisoning. Serious cases detected in this way were 21 per cent.

The investigator Dr J. V. Duhig states that lead poisoning does not exist without changes in the blood and that proper examination of the blood, and especially a study of the morphologic changes of the red cells by a person of great experience and patience, are absolutely essential to the diagnosis of plumbism. He expresses the view that compensatable disability in acute cases does not exist unless punctate basophilic has been demonstrated by a suitable standard of technic to the extent of at least 1,000 coarsely stippled cells per million. Less degrees of change are to him of importance only so far as the early diagnosis of the condition is concerned.

Recommendations are made regarding the prevention of the emission of flue dust from smelter stacks, the ventilation of tapping floors, the protection of persons entering furnaces, the ventilation of buildings, works and other places where lead processes are carried on, the maintenance of roads, pathways and yards so that dust shall not arise, the provision of overalls and close head covering, the use of respirators, the provision of meal places so that they shall not be exposed to dust or fumes from any manufacturing process, and the provision of drinking water that is not contaminated by dust. The danger of preparing cigarettes or cutting and rolling tobacco in lead dust atmosphere is mentioned.

The regular analysis of atmosphere air about the plant is recommended. In order to exclude these employees with a low lead tolerance, a probationary employment period of four months is suggested.

Medical School for Queensland University

After years of patient effort, the arrangements for the establishment of a faculty of medicine at the University of Queensland, situated in Brisbane, are now reaching a concrete form. The state government has appointed a committee to advise on the details of establishment. It will be necessary for the state treasury to make a grant for the purpose.

The serious difficulty of accommodation was recently overcome by the generous donation to the university by the Masons of Brisbane of their old Masonic temple. The building is a massive construction and requires only a little renovation and alteration to make it serve its new function. The lodge rooms are well adapted for lecture theaters and the anterooms can be readily converted into laboratories and administrative offices.

Limiting Students at the Universities

A few months ago a new law was sanctioned by the chamber of deputies which limits the employment of members of the minority nationalities to 10 per cent of the Rumanian workers in any given commercial enterprise. Some extreme nationalists are now trying to extend this principle also to the granting of medical and legal diplomas. This new kind of *numerus clausus* is already being practiced in the faculties of medicine. In fact, the number of minority students is even less than 10 per cent. Some Rumanian newspapers attacked Professor Martinescu, dean of the medical faculty of the Cluj University, for being too lenient in the enrolment of minority and chiefly Jewish first year students. The dean explained his attitude as follows: The professorial board resolved to admit 150 first year students. The applicants have to write a thesis in physicochemistry, natural history and hygiene. Out of 241 applicants, all of whom duly passed the examinations, ninety have been rejected. The number of first year students, including repeaters, was 233, of whom 144 were Rumanians, thirty-nine Hungarians, thirty-six Jews, eleven Germans, two Bulgarians and one Albanian. The dean remarked that applicants of Rumanian nationality, without regard to the examination, all could enrol. He gave expression to his conviction that the universities should be thrown wide open, so that every one wishing to study should be able to do so.

The Strike of Bucharest Medical Students

A short time ago the students of the legal faculty of the Bucharest University went on strike, to demonstrate against the excessively high examination fees. The medical students followed suit, as they have to pass more examinations than the law students, and the examination fees are higher. They stopped going to lectures, so that the professors found only empty benches. They demand a system like that prevailing in France, namely, in lieu of numerous final examinations to have a final examination for the doctor's degree after the completion of all university semesters. The minister of public instruction is inclined to make a radical change on the present examination system. At Bucharest University, medical students now have to pass altogether thirty-eight examinations during the prescribed six years study, yet, at the completion of the studies, examinations have to be passed anew even on theoretical subjects.

The dean of the faculty of medicine announced to the students that the board of professors feels inclined to comply with their request and to pass their appeal, for approval, to the

ministry The students said that they are not satisfied with promises but will continue to strike until their appeal is definitely settled by an official enactment Thereupon the professorial board appealed to the ministry for a decision, and the students stopped striking

A Reward for Practicing in Villages

At a recent meeting of the chamber of deputies, the draft of a bill to provide villages with doctors was voted Ioanintescu, late minister of labor and public health, said that while in cities the ratio of physicians is 1 375 of population, in villages one doctor provides medical service to between 25 000 and 30 000 The present minister of public health stated that in some places there is one doctor to twenty or twenty-five villages and that distances are so great that if the doctor is called to a patient it requires a full day for the visit, during which time the rest of the people are without medical service The roads are bad and he is dependent on horse and carriage The mortality rate in children is the highest in Europe Our duty said the minister, is to induce physicians to leave the towns and settle in villages There are two solutions to this question Either to increase the number of village doctors by extending social insurance to the villages or to give a premium to physicians who settle in villages and who pledge themselves to remain there

Faculty of Medicine Closed

At the faculty of medicine of the Bucharest University, antisemitic movements gained such headway that the board of the faculty saw it necessary to prevent further disturbances to suspend the holding of lectures until April 10, that is six days from today The board of professors told the instigators that if they do not stop demonstrations the faculty of medicine will be closed for a longer period and then they will lose the present semester The board discussing the question of the memorandum of the non-Jewish students in regard to the introduction of the "numerus nullus" resolved to put the leaders of the movement before the disciplinary committee Several antisemitic incidents occurred

A New Law Against Adultery

The new Rumanian penal code includes the crime of adultery The text of the law is as follows Extramarital sexual relation of either member of a married couple is considered the crime of adultery, for which the punishment ranges from one to twelve months in prison but, if the relation is carried on after the court trial the punishment is from six to twenty-four months in prison Criminal process can be started only on the complaint of the innocent mate The innocent party may pardon his spouse at any phase of the trial even subsequent to the announcement of the punishment

Marriages

BENJAMIN FRANKLIN COZART to Miss Helen Rebekah Newell, both of Reidsville, N C., May 18

GEDEON ARAM BELHUMEUR, Gardner Mass., to Miss Rose Lagueux of Levis, Que., April 30

JACK ALEXANDER MCKENZIE Jackson, Tenn. to Miss Edith Woodard of Miami Fla., May 18

PHILIP DAVID SROUT, Bristol, Va. to Miss Julia Holston Slack of Bristol, Tenn., April 17

RAYMOND D LUBLIN, East Hartford Conn., to Miss Anne Hurowitz of Hartford, April 14

PAUL Q BAKER, Axtell Neb. to Miss Dorothy De Armon of Cheyenne, Wyo., April 23

CLARENCE DIXON FOWLER to Miss Mary Susan Prim both of Atlanta, Ga., April 19

LEE B WORD, Los Angeles, to Miss Allethia Averett of Atlanta Ga. April 13

EDWARD HOLLANDER to Miss Ruth E. Fineman both of New York recently

Deaths

Jesse Leroy McElroy, Neuilly-Sur-Seine, France, Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907, since 1933 superintendent of the American Hospital in Paris, served during the World War, formerly superintendent of the hospitals (Memorial, Dooley and St Philip) of the Medical College of Virginia Richmond, St Lukes Hospital, Chicago the University Hospital, Iowa City, Iowa Ancker Hospital, St Paul, and St. Marks Hospital, New York, aged 50, died suddenly, May 5, of heart disease.

Harry Winfred Goodall ☉ Boston, Harvard University Medical School, Boston, 1902, fellow of the American College of Physicians, served during the World War, at one time lecturer on digestive diseases, Dartmouth Medical School Hanover, N H., and instructor in chemistry at his alma mater on the staffs of the New England Deaconess Hospital and the New England Baptist Hospital, Boston, the Burbank Hospital Fitchburg, the Chelsea (Mass.) Hospital and the Framingham (Mass.) Union Hospital, aged 58, died, April 17

Wilbur Hawley Gilmore ☉ Chicago, Jefferson Medical College of Philadelphia, 1903, member of the Radiological Society of North America, served during the World War member of the professional committee for medicine, Illinois Department of Registration and Education secretary of the Illinois State Medical Society 1913-1922, attending roentgenologist to the Illinois Masonic Hospital and the Illinois Eye and Ear Infirmary, aged 55, died April 27, of coronary thrombosis

Henry Burtis Costill ☉ Trenton, N J., University of Pennsylvania Department of Medicine Philadelphia 1882 member of the House of Delegates of the American Medical Association 1918, 1925 and 1927, formerly director of the New Jersey State Department of Health, past president of the Medical Society of New Jersey and the Mercer County Medical Society, president of the staff of St. Francis Hospital, aged 75, died April 27 of cerebral hemorrhage

George Robert Elliott ☉ New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York 1881 formerly assistant professor of clinical orthopedic surgery at his alma mater fellow of the American College of Surgeons, consulting orthopedic surgeon to the Montefiore Hospital attending orthopedic surgeon to St. Francis and St. Joseph's hospital, died, April 27

Frank J. Holdsworth, Traverse City, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor 1900, member of the Michigan State Medical Society member of the American Academy of Ophthalmology and Oto Laryngology, on the staff of the James Decker Munson Hospital, aged 60, died, April 4, in the Presbyterian Hospital, Chicago of coronary thrombosis

Ernest Mozart Roseberry, Neosho Mo., Chicago Physio-Medical Institute 1890 Barnes Medical College St. Louis 1904 member of the Missouri State Medical Association deputy state health commissioner formerly member of the state legislature, served during the World War, aged 68, on the staff of the Sale Hospital, where he died, March 21 of angina pectoris

Nelson Wilson Janney, San Diego Calif., University of Pennsylvania Department of Medicine, Philadelphia 1906 member of the American Society of Clinical Investigation served during the World War, formerly on the staff of the New York Post Graduate Hospital, New York, aged 53, died, April 29, of chronic nephritis and arteriosclerosis

Henry Aaron Norden, Chicago, Rush Medical College Chicago, 1889, formerly junior dean and professor of medicine, Loyola University School of Medicine school health officer of Chicago, 1914-1923, fellow of the American College of Physicians aged 68 died May 1, of hemiplegia, hypertension and arteriosclerosis

Edward Nathan Schoolman, Chicago Chicago College of Medicine and Surgery, 1914, member of the Illinois State Medical Society, at one time medical director of the Elgin (Ill.) State Hospital, on the staff of the Michael Reese and Mount Sinai hospitals aged 41 died, May 15, of coronary thrombosis

Jay Sproat McCulloch, Wellsville, Ohio Ohio Medical University Columbus 1904 member of the Ohio State Medical Association for many years member of the board of education at one time bank president health officer of Wellsville on the staff of the East Liverpool (Ohio) City Hospital, aged 59 died, April 24

Isaac Wilsey Traverse, Fort Madison, Iowa, Keokuk (Ia.) Medical College, 1893, member of the Iowa State Medical Society past president of the Lee County Medical Society served during the World War, on the staff of the Sacred Heart Hospital, aged 62, died, April 12, of cerebral hemorrhage

James Archibald Orbison ♂ Major M C, U S Army, North Bergen, N J, University of Illinois College of Medicine, Chicago, 1913, served during the World War, appointed first lieutenant in the medical corps of the U S Army in 1917 and was promoted major in 1929, aged 47, died, April 24

Edward Harvey Griswold, Peru, Ind, University Medical College of Kansas City, 1891 member of the Indiana State Medical Association, fellow of the American College of Surgeons aged 80, formerly medical director of the Wabash Railroad Employees Hospital, where he died, April 5

Clesson Beckwith ♂ Lieut, M C U S Army, Corning Iowa, State University of Iowa College of Medicine, Iowa City 1932, entered the medical corps of the U S Army as a first lieutenant in 1933 aged 29 died April 4, in Fort Des Moines of pulmonary embolism following an appendectomy

Ben Hicks Metcalf ♂ Ruskin Fla, Harvard University Medical School, Boston 1894 member of the Massachusetts Medical Society, served during the World War, in 1906 he established the Metcalf Hospital, now known as the Winthrop Community Hospital, aged 64 died March 31

Thomas Paul Martin ♂ Taos, N M College of Physicians and Surgeons, Baltimore, 1887 connected with the Indian Service health officer of Taos County served during the World War, aged 70 died April 11, in St Vincent's Hospital Santa Fe, of cerebral hemorrhage.

George Potter Edwards, Nashville, Tenn, Rush Medical College, Chicago 1882, at one time clinical professor of neurology, dermatology and electrotherapy Vanderbilt University School of Medicine, aged 76, died April 29, of acute multiple arthritis and senility

Roger Marvin Griswold, Kensington Conn University of the City of New York Medical Department, 1875 member of the Connecticut State Medical Society past president of the American Association for Clinical Research aged 82 died, April 28

Eugene Ballantyne Sharpe, Manti, Utah Jefferson Medical College of Philadelphia 1898 member of the Utah State Medical Association, served during the World War aged 60 died April 29, of chronic myocarditis and congenital polycystic kidney

Clifford Henry Griffin ♂ Providence R I, Harvard University Medical School, Boston 1898 for many years police surgeon, formerly member of the school committee and state legislature aged 64 died April 1, in the Jane Brown Hospital

James Wallace Horner, Alma, Mo, Jefferson Medical College of Philadelphia, 1877, member of the Missouri State Medical Association past president of the Lafayette County Medical Society aged 81 died March 15 of hypostatic pneumonia

James Pringle Elliott, Laguna Beach Calif Dartmouth Medical School, Hanover N H, 1887 University of the City of New York Medical Department 1887 aged 82 died February 28 of cerebral endarteritis and arteriosclerosis

David Noble Kee ♂ Gladstone Mich McGill University Faculty of Medicine, Montreal, Que Canada, 1890 health officer of Gladstone, formerly member of the school board aged 74, died March 6 of pneumonia and influenza

James Edgar Wheat, San Fernando Calif University of Southern California College of Medicine, Los Angeles 1900 member of the California Medical Association aged 74 died February 9 of diabetes mellitus and acute nephritis

Field Vernon Gremillion, Alexandria La Tulane University of Louisiana Medical Department, New Orleans 1906 member of the Louisiana State Medical Society aged 56 died suddenly, March 27, at his home in Pineville

John William Hutton, Newton Ill Barnes Medical College St Louis 1899 and 1900 member of the Illinois State Medical Society, county coroner aged 57 was killed March 26 when he was struck by an automobile

William Noah Elkins ♂ Junction City, Ark University of Tennessee Medical Department Nashville, 1908 past president of the Union County Medical Society, aged 51, died March 12 of cardiorenal disease.

William Burnam Godard, Macon Ga University of Georgia Medical Department Augusta 1906 aged 53 died March 10 in the R F Strickland and Son Memorial Hospital Griffin of lobar pneumonia

Rufus Albert Hoover, Hope, Ind, Bennett Medical College Chicago 1912 member of the Indiana State Medical Association county health officer, aged 62 died, March 22, of carcinoma of the stomach

Travis Shaw Griffith, Georgetown Texas Harvard University Medical School, Boston, 1932 aged 28, intern at the Charles V Chapin Hospital, Providence, R I, where he died March 30 of meningitis

Thomas Barber, Phillipsburg, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1898 state senator aged 66 died April 29 in the Lankenau Hospital, Philadelphia of bronchopneumonia

Charles H Edwards, Terre Haute Ind Cincinnati College of Medicine and Surgery 1885 member of the Indiana State Medical Association, aged 76 died, May 6 in the Union Hospital of pneumonia

Clarence Maitland Service, Springfield Ill, Jenner Medical College, Chicago, 1902 inspector in the department of public works for the state of Illinois, aged 61 died May 3 of gastric carcinoma

Louis Wilson Talbott, Elkins W Va University of Maryland School of Medicine Baltimore, 1883 member of the West Virginia State Medical Association, aged 79 died March 17

Norval Cobbs Vaughan, Cincinnati Howard University College of Medicine, Washington, D C, 1896 aged 63 died April 20 of coronary thrombosis and angina pectoris

Pierce Edward Somers, Portland Maine Harvard University Medical School, Boston, 1903 aged 59, died February 26 of hypertensive heart disease nephritis and uremia

Francis Alexander Robert Gow, Greenwich, N S Canada Trinity Medical College, Toronto, Ont 1889 died February 13, in the Camp Hill Hospital Halifax

R M Manley, Cleveland Western Reserve University Medical Department, Cleveland 1904, served during the World War, aged 58, died, March 21, of heart disease

Levi Brook Hirst ♂ Camden N J, Jefferson Medical College of Philadelphia, 1894 on the staff of the Cooper Hospital aged 74 died March 6 of cerebral hemorrhage.

Herman Groth ♂ Pittsburgh Western Pennsylvania Medical College, Pittsburgh, 1902 aged 65, died, March 21 in St John's Hospital, of carcinoma of the colon

Hugh Gerald Williams, Vernon, B C Canada, Queen's University Faculty of Medicine, Kingston, Ont, 1894, aged 66, died, February 16 of valvular heart disease

Stephen James O'Brien ♂ Chicago Northwestern University Medical School Chicago 1907, aged 54 died May 7, of myocarditis and chronic nephritis

Willis E Hosman ♂ Akron, Ind, Eclectic College of Physicians and Surgeons, Indianapolis, 1892 aged 65 died, March 16 of coronary thrombosis

Alfred T Bennett, Louisville Ky Kentucky School of Medicine Louisville, 1861, Civil War veteran, aged 94 died April 23, of bronchopneumonia

Robert John Young ♂ Snow Shoe, Pa Temple University School of Medicine Philadelphia 1929 aged 34 died April 22 of heart disease

Charles H Wallace, Dallas Texas (registered by Texas State Board of Medical Examiners under the Act of 1907), aged 72 died, February 26

Alpheus Hamilton Gans, Abilene Kan University of Wooster Medical Department, Cleveland 1870, aged 88 died, February 9, of senility

John Hackworth Wood, Sweet Water Ala, Medical College of Alabama Mobile 1886 aged 70 died, February 23 of lobar pneumonia

Patrick J Flannery, Waverly N Y Baltimore Medical College 1895, died, March 10, of chronic endocarditis and arteriosclerosis

David Charles Wybourn ♂ Ossian Ind. Fort Wayne College of Medicine 1902 aged 56, died March 23 of acute appendicitis

Ambrose C Clifford Jr, Bedford Ind Kentucky School of Medicine Louisville 1893 aged 77, died, March 13 of pneumonia

Emilio Raphael Tobia Los Angeles, Bennett College or Eclectic Medicine and Surgery Chicago 1910 aged 60 died February 9

Henry M Hunt, Chicago St Louis College of Physicians and Surgeons 1887, aged 85 died, April 16, of myocarditis

John Galen Locke, Denver Denver Homeopathic College 1904 aged 63 died, April 1 of coronary thrombosis

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

Foster's White Camphor Liniment—Keystone Manufacturing Co. South Boston Va. Composition Essentially volatile oils including camphor, with ammonia (about 2 per cent) soap and water. Fraudulent therapeutic claims.—[N J 21232 August 1934]

Mineralorystals—Mineral Wells Crystal & Water Co. Mineral Wells, Texas. Composition Essentially dried Glauber's salt (over 98 per cent) with small amounts of common salt and the carbonates of calcium, magnesium and sodium. For rheumatism neuritis stomach kidney and bladder disorders etc. Fraudulent therapeutic claims.—[N J 21236 August 1934]

Slp D—McCahe Drug Co. Fargo N. D. Composition Essentially plant drug extracts menthol tar chloroform sugar and water. For coughs bronchitis asthma catarrh fever etc. Fraudulent therapeutic claims.—[N J 21238 August 1934]

Sauer's Nerve and Bone Oil—C. F. Sauer Co. Richmond Va. Composition Essentially wintergreen, camphor menthol camphor oil and eucalyptol, colored green. For rheumatism tumors toothache etc. Fraudulent therapeutic claims.—[N J 21239 August 1934]

Astra Asthma Rollers—Superior Medicated Products Corporation, New York. Composition Stramonium leaves in cigaret form. For asthma bronchitis catarrh sore throat etc. Fraudulent therapeutic claims.—[N J 21245 August 1934]

Apinol—Apol Corporation Wilmington N. C. Composition Essentially pine oil. For sores burns pyorrhea boils blood poison lockjaw typhoid etc. False therapeutic claims.—[N J 21248 August, 1934]

Fowlerino—Fowler Medicine Co. Memphis Tenn. Composition Sulphonated oil turpentine and methyl salicylate. For kidney bladder and rheumatic disorders indigestion diabetes dropsy, etc. Fraudulent therapeutic claims.—[N J 21249 August 1934]

Lee's Antisepiline Powder—Moore & Co., Inc. Worcester, Mass. Misbranded because not a germicide and contained no aluminum sulphate or oxquinoline sulphate as claimed.—[N J 21250 August 1934]

Idan Ha Lithia Water—Idan Ha Mineral Water Co. Soda Springs Idaho. Composition Essentially a moderately mineralized water containing chiefly magnesium limestone but very little lithia, hence the term "Lithia Water" was false and misleading constituting misbranding.—[N J 21501 August 1934]

M. R. Son Pink Wonders—M. R. Son Co. Inc., Boston. Composition Tablets each containing 25 grains of acetphenetidin and 35 grains of aspirin. For sciatica lumbago earache, toothache and periodical pains. Fraudulent therapeutic claims.—[N J 21502 August 1934]

Johnson's (Clark) Syrup—Kells Co. Inc. Newburgh N. Y. Composition Essentially plant drug extracts including aloe with alcohol sugar and water. For stomach, liver and bowel disorders etc. Fraudulent therapeutic claims.—[N J 21503 August 1934]

Royce Antiseptic Solution—National Medical Products Co. Los Angeles. Composition Essentially small amounts of boracic acid volatile oils including wintergreen and thymol with oxyquinoline sulphate and water. For feminine hygiene pyorrhea sores body rash etc. Not antiseptic when used as directed. Fraudulent therapeutic claims.—[N J 21507 August 1934]

Espiritu Water No. 1—Espiritu Water Co., Safety Harbor Fla. Composition A moderately mineralized water chiefly containing common salt, with other mineral substances found in ground waters. For stomach disorders Bright's disease diabetes, dropsy psoriasis etc. Fraudulent therapeutic claims.—[N J 21508 August 1934]

Almklov's Eczema Specific—S. Almklov Cooperstown N. D. Composition Essentially zinc oxide (11 per cent) ammoniated mercury (9 per cent) and small amounts of camphor and menthol in a petrolatum base. Fraudulent therapeutic claims.—[N J 21509 August 1934]

Yorba Vida—Yorba Vida Co. Los Angeles. Composition Essentially an American species of the plant ephedra. Cure-all and rejuvenator. Fraudulent therapeutic claims.—[N J 21511 August, 1934]

Compound Epsom Salt Tablets—Hance Bros. & White Inc. Philadelphia. Composition In each tablet 51 grains of epsom salt and 35 grain of phenolphthalein. Adulterated because below professed standard of purity and because name Compound Epsom Salt Tablets was false and misleading in that phenolphthalein was the active ingredient.—[N J 21512 August 1934]

Stuart's Dyspepsia Tablets—F. A. Stuart Co. Marshall Mich. Composition Large tablets essentially calcium carbonate magnesium carbonate ginger sugar and starch small tablets essentially calcium carbonate plant drug extracts including red pepper and a bitter drug with sugar and starch. For dyspepsia stomach ulcers bad breath heart burn etc. Fraudulent therapeutic claims.—[N J 21513 August 1934]

Lady Grace Mineral Crystals—Grace Natural Mineral Co. Omaha. Composition Essentially crystallized Glauber's salt with a trace of common salt. For obesity constipation rheumatism Bright's disease, etc. Fraudulent therapeutic claims.—[N J 21516 August 1934]

Key Tasteless Cod Liver Extract Tablets—Key Laboratories Chicago. Composition In each tablet 8.3 milligrams of chloroform soluble material including fatty material and a bitter drug extract, in a mixture of starch, sugar and tale. For building up. Fraudulent therapeutic claims.—[N J 21518 August 1934]

Garvin's Romodios—Pest U Di Chemical Co. Chicago. Composition Essentially horic acid potassium permanganate and water. For "female weakness" diphtheria canker, etc. Fraudulent therapeutic claims.—[N J 21519 August 1934]

Manam Sylladox—Natural Health Products Co., New York. Composition About 80 per cent Plantago ovata and about 20 per cent of brownish particles containing a considerable proportion of ground carob bean cacao a reducing sugar such as lactose, and a very small amount if any, of dextrin. Misbranded because of false and misleading claims as to composition and because of fraudulent therapeutic claims for efficacy in diarrhea stomach hyperacidity, etc.—[N J 21521 August 1934]

Savol—Savol Chemical Co. Mercer Pa. Composition Essentially phenols (including 55 per cent of carbolic acid) soap and water. For infections catarrh hay fever, etc. Fraudulent therapeutic claims.—[N J 21522 August 1934]

Penslar Sore Throat Gargle—Peoples Drug Stores Washington, D. C. Composition Essentially potassium chlorate ferric chloride glycerol alcohol and water. Fraudulent therapeutic claims.—[N J 21523 August 1934]

Penslar Children's Cough Syrup—Peoples Drug Stores Washington D. C. Composition Essentially plant drug extracts including ipecac, with flavoring materials alcohol sugar and water. Fraudulent therapeutic claims.—[N J 21523 August 1934]

Ingraham's Macodanlan Oil—Gerlach Medicine Co. Wooster Ohio. Composition Essentially a nonvolatile oil with 2 per cent of volatile oils including eucalyptol, menthol camphor and wintergreen. For rheumatism catarrh diphtheria liver and kidney troubles piles asthma etc. Fraudulent therapeutic claims.—[N J 21525 August 1934]

Rinox—Rinox Laboratories Co., Cleveland Ohio. Composition Capsules each containing acetphenetidin 1 grain aspirin 2.5 grains, quinine 0.17 grain camphor, and a laxative drug and tablets each containing 4 grains of baking soda and starch. For asthma hay fever catarrh colds etc. Misbranded because acetphenetidin not properly declared on label and because of fraudulent therapeutic claims.—[N J 21526 August 1934] This nostrum was discussed in detail in THE JOURNAL April 11 1925 and in H₂gria for June 1929.

Electrovita Mineralized Water—Electrovita Co. Inc. Norwalk Ohio. Composition Essentially diluted lime water. To combat harmful acids and assist nature in the elimination of waste matter. Fraudulent therapeutic claims.—[N J 21527 August 1934] This "patent medicine" was the subject of an article in THE JOURNAL, Jan 23 1932.

Cox's Liniment—Hoover Liniment Co. Carlisle Ind. Composition Essentially turpentine oil an iodine compound linseed oil, a petroleum product and carbolic acid. Fraudulent therapeutic claims.—[N J 21528 August 1934]

Carpathian Herb Tea—Polonia Medicine Co. Philadelphia. Composition Essentially senna leaves juniper berries chamomile flowers, fennel seed pennyroyal herb and sweet orange peel. Cure-all. Fraudulent therapeutic claims.—[N J 21530 August 1934]

Freesh's White Pine and Cherry Compound Cough Syrup—Atlantic Sales Corporation Rochester N. Y. Composition Essentially plant drug extracts including wild cherry and ipecac, with ammonium chloride menthol alcohol sugar and water. Fraudulent therapeutic claims.—[N J 21532 August 1934]

Rogers' Headache Soda—Rogers Drug Co. Memphis Tenn. Composition Essentially acetanilid (33 grains per powder) caffeine and baking soda. Fraudulent therapeutic claims.—[N J 21533 August 1934]

Aromat—T. J. Holmes Co. Inc. Chantley Mass. Composition Essentially volatile oils (about 13 per cent) including lavender and cardamom oils menthol camphor and eucalyptol with alcohol and small amounts of glycerin and water. For sore throat skin infections influenza etc. Fraudulent therapeutic claims.—[N J 21534 August 1934]

Autotoxine—Autotoxine Co. Ottawa Kan. Composition Essentially epsom salt in water sweetened with saccharine. For rheumatism head ache sour stomach, neuralgia etc. Fraudulent therapeutic claims.—[N J 21536 August 1934]

Sleepy Salts—Sleepy Water Co. Chicago. Composition Essentially Glauber's and epsom salts with a small amount of common salt. For obesity rheumatism nervous disorders etc. Fraudulent therapeutic claims.—[N J 21537 August 1934] This nostrum was the subject of an article in this department of THE JOURNAL, May 5 1934.

Pulvis Alkantis—Lafayette Pharmacal Inc. Lafayette Ind. Composition Essentially calcium carbonate, magnesium carbonate bismuth subcarbonate cerium oxalate and a small amount of menthol. For gastric ulcer, acute gastric catarrh etc. Fraudulent therapeutic claims.—[N J 21540 August 1934]

Griswold's Family Salve or Plaster—Sisson Drug Co. Hartford Conn. Composition Essentially lead oleate and rosin. For boils wounds ulcers hard tumors etc. Fraudulent therapeutic claims.—[N J 21541 August 1934]

Nash's Purpative Tablets—Nash Bros. Drug Co., Jonesboro Ark. Composition Essentially mercurous chloride phenolphthalein and an extract of a laxative plant drug. Fraudulent therapeutic claims.—[N J 21543 August 1934]

Nash's Headache Tablets—Nash Bros. Drug Co. Jonesboro Ark. Composition Essentially acetphenetidin aspirin phenolphthalein and caffeine. Fraudulent therapeutic claims.—[N J 21543 August 1934]

Correspondence

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

To the Editor—I was interested in reading the report of the Council on Medical Education and Hospitals as published in *THE JOURNAL*, March 30. I was particularly interested in comments relative to obstetrics and the report of the Committee on Maternal Mortality of the New York Academy of Medicine. You are probably cognizant of the volume published by the White House Conference on Child Health and Protection which deals with the question of obstetric education. This report was rather carefully prepared after a comprehensive study and it should be of assistance to the Council on Medical Education and Hospitals as well as others who are interested in improving obstetric education in this country.

The comments in paragraph 3, page 1065, were of interest. I think that the Council is under some misapprehension since the American Board of Obstetrics and Gynecology does not attempt to draw an arbitrary line between surgery of the reproductive organs and other contents of the abdominal cavity. We do attempt to draw a line between men who practice abdominal surgery in the male and in the female. The gynecologist who invades the abdomen does so primarily to deal with pelvic conditions. The general abdominal surgeon, especially in dealing with the male patient, usually invades the abdomen for some condition above the pelvic level. The board expects the qualified obstetrician and gynecologist to be able to deal with surgical conditions in the abdomen, but we do not expect him to invade the abdomen as a part of his routine practice, except for gynecologic conditions. The board has therefore ruled that a man accepting male patients in his practice is not eligible for certification by the board. He must be a specialist in obstetrics and/or gynecology.

Furthermore, the American College of Surgeons has already designated competent specialists in the various surgical fields. Their selection is based on the theory that the best available man in the community should be so designated. Our board has taken the position that a man must prove himself to be a qualified and bona fide specialist without reference to his geographic location.

Lastly, I should like to call your attention to the fact that the men who constitute these special boards are facing the facts. They are men who are in actual practice and know something of the problems of the medical profession from daily contact with them. So far as I know the Council criticized and more or less condemned the action of our board without making any direct attempt to discover from its members what its attitude is. So far as my personal contact with the members of the board is concerned, I believe that no one of them feels that the final attitude of the board is crystallized and unchangeable. The principal idea of the board was that the specialty of obstetrics and gynecology should be placed on a higher plane in this country than it has occupied in the past.

The members of the board are selected by various special societies including the section of the American Medical Association presumably for their fitness to deal with these problems. The board members endeavor to represent and interpret the opinions of the special societies which they represent, and also of those who have been certified as specialists by the board.

While I am a member of the board this letter in no way represents any action or conference with other members of the board. I am sure the board is attempting to take a fair attitude toward all and so far as any actions taken by the board with which I am connected are concerned I fail to see that they have been actuated either by favoritism or by prejudice.

FRED L. ADAIR, M.D. Chicago

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

MYCOTIC INFECTIONS IN CANNERIES

To the Editor—In my city there is a packing plant where tomatoes, beans and corn are cooked in various ways, packed in hot cans and prepared in differing types of marketable products. Meats as well are now being cooked and packed. Every few days a worker comes in with a swollen finger from this plant. He may or may not have sustained a scratch or bruise before the swelling begins. Sometimes there is a blister where the swelling is greatest. From day to day these fingers grow worse. The swelling will extend to the tip of the finger and back to the hand. It becomes tense and the feel of the finger is hard. Blistering may extend over much of the swollen area or a lesser amount but later it will extend over the entire swollen area. The adjoining finger or fingers may become involved after three to ten days though not so seriously as the first. The blistering and infiltration may extend even into the hand. The pain due to the tense swelling is marked. There will probably be a focal spot of greater intensity where the swelling is worst and some necrosis will be found under a degenerating blister. One will feel inclined to drain at this point but so far I have never got anything except blood and a little serum. Necrosis continues with or without drainage (incision) over a wide area sometimes from the tip of the finger to the hand. Sloughing will expose the sheaths and ligaments and extend down into the joints where it may expose the bones. A large wide open necrotic sore is the result. It heals slowly. The whitened surfaces of the sore make one fear that red granulations will never appear. The sore seems forever in casting off the necrotic detritus and in bringing to light living tissues. I have opened these fingers early and late, always regretting that I opened them at all and now I do not drain but allow them to drain through their own efforts. Hot applications do not even relieve the pain very much and certainly do not greatly shorten the course. What causes these juice sores to behave so strangely? What is the proper treatment?

E. O. HARROLD, M.D., Marion, Ind.

ANSWER.—The lesions described at once suggest the presence of virulent mycotic parasites. Lately a new fungus has been described by Thiene as the causative agent of an occupational disorder among workers in canneries. This new organism resembles *Monilia* and *Parasaccharomyces* but as yet this organism has not been finally classified. *Moniliasis* is itself a distinct possibility. The treatment for these fungic infections is the same as for mycotic lesions in general. Roentgen therapy has some merit. These conditions are more particularly associated with vegetable canneries, but it is observed in the query that meats likewise are packed. "Butchers dermatitis" is a well established occupational disease entity and perhaps has best been described by Schwartz (*J Indust Hyg* 13:233 [Sept.] 1931). His summary is as follows:

1. Butchers' dermatitis, characterized principally by erythematous areas on the hands followed by the appearance and subsequent eruption of pinhead vesicles, and accompanied by considerable itching as a symptom, is an occupational disease largely affecting butchers and inspectors who handle freshly killed carcasses.

2. The lesions which first appear on the webs of the fingers and spread to the sides and backs of the fingers and to the backs of the hands as far as the wrists, may extend up the arms as far as the elbows and in exceptional cases may spread to other parts of the body, such as the chest, abdomen, legs and face.

3. The disorder does not appear immediately on the exposure of susceptible persons but usually makes its appearance after an initial period of exposure varying from three to thirty days during which time susceptible persons presumably become sensitized to the tissues and fluids of swine, cattle and sheep.

4. While certain persons make a rapid recovery following the first attack, with or without treatment, others develop repeated attacks while the exposure to the inciting cause is continued in some persons the susceptibility lasts for several years.

5. The available evidence indicates that many seasoned workers lose their susceptibility to the disorder in the course of time.

6. While most susceptible persons appear to become fairly equally sensitized to the various classes of meat food animals that are slaughtered in abattoirs certain persons exhibit a specific susceptibility to one or two classes of these animals and are unaffected by contact with others.

7. The dermatitis may be checked by various local applications commonly used in treating related skin troubles in which there are no constitutional symptoms.

8 On the basis of available evidence, frequent washing of the hands in cold running water, thorough scrubbing of the hands with soap and brush at the end of the day's work, and coating the hands with petrolatum or other ointments before beginning the day's work are in most cases effective prophylactic procedures.

Schwartz's paper indicates the absence of precise knowledge of the causative agent of "butchers' dermatitis," but again it is believed that fungi of divers sorts may be the cause of some outbreaks. Different forms of mycotic organisms probably are responsible for the variations in severity, incidence and characteristics. Suggestions as to treatment are scarcely warranted in this situation until greater information is available as to the cause of the disorder. Chief emphasis at this time is placed on the desirability for carrying out microscopic examinations of skin scrapings, fluid discharges and culture materials for the purpose of establishing the exact nature of the offending parasite.

TREATMENT OF PYELITIS IN PREGNANCY

To the Editor—I was called in to see a pregnant woman aged 19 a primipara at the sixth month. She was complaining of pain of several days duration in her back also fever, nausea and vomiting. The pain was sharp and colicky in character and did not radiate. The temperature was 103.2 F the pulse 120 per minute and respiration 22 per minute. The blood pressure was 122 systolic 62 diastolic. Physical examination revealed nothing of note except tenderness in both costovertebral angles and in the lower midline of the abdomen. A diagnosis of pyelitis of pregnancy was made and confirmed by a urine examination. The latter showed an abundance of pus and moderate albumin but no casts or red cells. Alkalinization of the urine with sodium bicarbonate was attempted for three days with no improvement either in the severity of the pain or elevation of temperature. Urophosphate tablets were then given one tablet three times a day for four days without effect. The pain became more severe so that there was a suspicion of kidney stone. The patient was removed to a hospital where a flat roentgenogram of the abdomen was made. No stones were visualized. The urine still showed only pus and albumin and no red cells or casts. The white cell count was 13 000. It was decided to wash the kidney pelvis through ureteral catheters. A consultant suggested first trying intensive methenamine therapy. In four days the temperature was normal the pain relieved and the patient sent home although the urine still showed some pus. Previous to the patient's discharge from the hospital the urine had shown some red cells and an occasional cast. This was attributed to the urophosphate compound. The latter was therefore discontinued and pyridium was substituted. The casts and red cells cleared up. At home two urophosphate tablets were given three times a day for several days and then a course of pyridium two tablets three times a day. The temperature shot up suddenly to 104 on the day after discharge from the hospital. It gradually dropped to normal after a few days. With reduction in the dose of the urophosphate compound however the temperature has risen again. The urine has continued to show pus and albumin (but no casts or red cells) although in lesser amounts. The temperature will be subnormal or normal in the morning and rise to about 102 in the afternoon. Attempts to get the patient up in bed result in an exacerbation of the condition. It has now been over three weeks since I first saw the patient and the improvement has been only slight. The patient is extremely desirous of having her baby and would like to avoid returning to the hospital for the ureteral washing for financial reasons. The latter condition however can be surmounted. I would like your opinion regarding the handling of this patient in respect to the pyelitis and the remainder of this pregnancy and in preparation for future pregnancies. I might add in closing that there is now no pain in the back. The patient has suffered considerably from flatulence. A light high protein diet was given in view of the lack of any toxic symptoms and small salt water enemas were given. This seems to have relieved the condition. Please omit name. M D District of Columbia

ANSWER.—In this case the treatment carried out represents the latest known in pyelitis. The restraint in the use of the ureteral catheter is commendable because of the acuteness of the disease but, now that the inflammation is in a more subacute stage, it might be desirable to put a catheter into the kidney pelvis and leave it there for several days, in the meantime keeping up alternating alkaline and acid treatment. One need not fear toxemia from a high protein ketogenic diet, which lately is being much used in pyelitis. Under the acid treatment, liquids should be restricted. Under the alkaline they should be greatly increased, the idea being to wash the kidney pelvis.

Change of posture is very important and the patient should assume the knee-chest or elevated Trendelenburg or alternating elevated Sims position frequently and for considerable lengths of time.

Unless the patient improves under these measures it would be advisable to empty the uterus because this would hasten the cure and would give her a better chance to enter later pregnancies with undamaged kidneys.

If the pyelitis is bilateral the emptying of the uterus is more strongly indicated.

POISONING FROM CREOSOTE

To the Editor—A man, aged 60 has adjoining his home on the south an unvalued lot on which is stored a carload or so of creosote lumber which is all the way from 10 to 60 feet from his home. Last summer the man complained of loss of appetite, a nauseated feeling, vertigo, and increasing deafness, especially in one ear. Examination was entirely negative except for a scarred tympanic membrane. The symptoms were not appreciably altered by thorough elimination. The summer was long dry and hot with an almost constant wind blowing directly from the creosote timbers into the man's home. His business a small repair shop is located in his residence, so that he was subjected to these fumes almost all the time. What are the signs and symptoms of creosote poisoning? Do you think it possible that any or all of these symptoms could be due to the symptoms described? Please omit name. M D Oklahoma

ANSWER.—Distinction must be drawn between real creosote poisoning and the condition described in this query. The creosote used for this purpose may be water gas tar or a complex mixture of various high boiling coal tar distillation products. Tarry acids are present, including various substances akin to cresols and phenols. The commonest disorder is a dermatitis, ordinarily produced only by direct contact but occasionally from vapors existing near treated woods. Commonly this creosote material is regarded as not evaporating. This is relatively true on comparison with the evaporation of water or naphthalene. However, some drying out does take place, particularly in hot weather, with the result that persons near extensive drying out surfaces may become involved. Track walkers walking on hot days along railroads having cross ties recently treated with creosote occasionally suffer from a dermatitis, nausea and distaste for food. In the case cited in this query it is unlikely that any association should be made between the creosote and the scarred tympanic membrane increasing deafness and possibly the vertigo. On the other hand, in the absence of any other plausible explanation the feeling of nausea and the loss of appetite may well be linked with creosote emanations under the circumstances of close proximity of the lumber pile and hot weather. Probably this action is not specific but might arise from almost any other disagreeable odor. A mental element undoubtedly contributes, for almost any one would be disturbed and irritated by the prolonged presence of offensive vapors of any character. Although odors are usually held blameless as the direct source of any disease state, it must be recognized that odors directly or indirectly bring about shallowness in breathing with some subsequent deprivation of the body of adequate oxygen, nausea, gastric discomfort, occasionally vomiting, and distaste for food. Creosote vapors are capable of bringing about this type of minor dysfunction and have been known so to do.

TREATMENT OF WARTS

To the Editor—I read with interest the report by Dr. Sophie A. Lurie in THE JOURNAL (Nov. 3 1934 p. 1399) on the treatment of warts with bismuth salicylate. Could you please send me detailed information such as interval of injections amount injected and so on and also whether it has been tried in the removal of moles also further references on the subject.

AARON BARCHAN M D New York

ANSWER.—A preparation of bismuth commonly used for intra muscular injection is the subsalicylate in a 10 per cent suspension of a vegetable oil. Of this, 1 or 2 cc. (from 0.1 to 0.2 Gm of the salt) is given once a week to adults.

The report of Dr. Lurie in Queries and Minor Notes in THE JOURNAL suggests that bismuth given in this way cures warts in just about 100 per cent of cases. A previous article by Dr. Lurie (Verrucae Vulgaris Palmar et Plantar, Treatment by Intramuscular Injections of Bismuth Salicylate, Arch Dermat & Syph 26 95 [July] 1932) reports the cure of thirty-four patients in a series of forty-nine treated. The result in the other fifteen could not be ascertained. At least one of the thirty-four cured could not be seen. The cure was reported by a nurse.

Two possibilities must be considered in attempting to explain this brilliant result. 1 That it was a coincidence that the warts cleared up soon after the treatment was begun. Goodman and Greenwood (Verrucae, Arch Dermat & Syph 30 659 [Nov.] 1934) criticize the reports on the cure of warts because they almost never include a control series, cases that were not treated, to compare the cases of spontaneous recessions with the percentage of cures after treatment. Dr. Lurie's successes were so many however and most of them occurred so promptly after the onset of treatment, that coincidence can hardly be held responsible. 2 That the drug is an active curative agent. This does not fit with the experience of many other dermatologists, who have given full doses of bismuth compound intramuscularly for many weeks without result. It can be said, however, that some patients are more susceptible to the action of the drug.

than are others 3 That the warts were cured by suggestion Dr Lurie makes no statement that she attempted to rule out this possibility as others have done (Cormia, F E Autolysate Treatment for Verrucae Vulgaris, *Arch Dermat & Syph* 30 44 [July] 1934) by discouraging the patient, mentioning that warts are very hard to cure, and so on Cormia's results were poor, favoring the theory of suggestion rather than the curative effect of the Biberstein autolysate, which he was testing

If a bismuth compound is used, the urine should be examined before treatment is begun and frequently during treatment and on the appearance of albumin or casts the treatment should be suspended A careful watch should be maintained for itching skin eruptions and the drug stopped until they can be cleared A blue line on the gums next the teeth indicates saturation with the drug, with impending stomatitis, and treatment should be discontinued if it appears Usually a series of eight weekly injections is considered a full course

Warts are thought to be due to infection with a filtrable virus Treatment with bismuth compounds is rational for such a disease. Moles are new growths in the skin probably benign epithelomas and there is no reason to expect bismuth compounds to have any effect on them

CANCER OF CERVIX AFTER CHILDBIRTH

To the Editor—Can you quote or refer me to statistics concerning the relative frequency of the occurrence of cancer of the cervix in women who after childbirth have had a trachelorrhaphy (or cauterization) as compared to those who after childbirth have not had done either of these procedures? I should like also to know the statistics on the occurrence of cancer of the cervix in all women as compared to those who have had done repairs or cauterizations of the cervix Please omit name and town

MD North Carolina

ANSWER—Lynch, writing for Davis's Gynecology and Obstetrics says "Carcinoma is the most frequent malignant tumor of the uterus. Usually it is primary and very rarely is it secondary from cancer in adjacent organs. Orth states that it forms 30 per cent of all carcinomas in women. It is responsible for at least 4 per cent of all gynecologic pathology. It kills more than 13 000 women annually in the United States (65 603 deaths from cancer of the uterus in the United States registration area 1925-1929 inclusive). 12 61 per cent of all cancer deaths are from cancer of the uterus these form 87 per cent of all deaths from cancer of the female genital organs (Hoffman)"

Lynch finds that the view that nulliparity or even virginity protects women from the chance of cervical cancer can be disproved from properly prepared reports, which show the relative proportion of cancer in nulliparous and multiparous women of the cancer age in the entire population

It would seem that it is the long continued chronic irritation of the cervix which is important, and all writers appear to agree that early cervical cancer is rarely found in women who have healed scars of cervical tears. Reference is commonly made to the report of Graves, who made a follow-up study of 6 000 women who had cervical repairs (not to remove the lacerations but to remove the infected areas contained therein) and found that only two women thus treated had developed cancer of the cervix at the time the study was made. Furthermore the history of women who have cancer of the cervix shows that relatively few have had either regular pelvic examinations or treatment of chronic irritations of the cervix. Thus far most of the statistical studies must be considered inadequate and the conclusions suggestive rather than absolute but gynecologists are generally of the opinion that the treatment of cervical irritations and lacerations definitely lessens the risk of cervical cancer

MYOSARCOMA OF BREAST

To the Editor—I am interested in available literature on myosarcoma of the breast

J L Fourn MC Lancaster Pa

ANSWER—Reports on myosarcoma of the breast are difficult to locate because of the confused terminology used in reporting mammary sarcoma. The literature on sarcoma of the breast has been brought down to the present in articles published in the *Annals of Surgery* from 1915 to 1934

S L Fox in his recent paper (Sarcoma of the Breast *Ann Surg* 100 401 [Sept] 1934) reviews the reports of S H Gest and A O Wilensky (Sarcoma of the Breast, *Ann Surg* 62 11 1915) Rigney, D Aunov and R W Wright (Sarcoma of the Breast *Ann Surg* 92 1059 [Dec] 1930) collected sixty-eight additional cases including seven of their own, and in 1932 B F Schreiner and A A Thibaudau (Sarcoma of the Breast, *Ann Surg* 95 453 [March] 1932) added seven more

Some of these cases were probably myosarcomas that were not distinguished by the authors and were loosely grouped under mixed tumors or fibrosarcoma. Figures 9, 10 and 11, page 408, in Fox's article is a probable myosarcoma, although at the time of publication he regarded the tumor as possibly of neurogenic origin. The sections have been restudied. The sixth case of Schreiner and Thibaudau is a probable myosarcoma, although described as composed of spindle, round and giant cells

Gaudier, Grandclaude and Lambret (Tumeur maligne du sein a type myoepithelial *Ann anat path* 8 68 [Jan] 1931) report a mild epithelial tumor of the breast, which they thought was malignant

Leroux and Chaton (Dysembryome complexe de la glande mammaire, *Bull Assn franç pour l'etude du cancer* 22 80 [Jan] 1933) have reported a fibrorhabdomyosarcoma of the mammary gland and (Voluminoso sarcoma ad elementum polymorfi e giganti della mammella *Cancro* 3 226 1932) gives illustrations of a possible sarcoma of this type under the heading of Large Polymorphous and Giant Cell Sarcoma of the Breast. Both of these last two articles are abstracted in the *American Journal of Cancer* 20 906 (April) 1934

BURSITIS

To the Editor—About two months ago while I was removing a prepatellar bursa under local anesthesia the sac was ruptured making it a little uncertain as to whether it was removed in its entirety. The patient was permitted to be up and about forty-eight hours after the operation. At this time serum continues to discharge several drachms daily and if the skin incision should be permitted to close the condition would apparently recreate itself. What is the best procedure to follow in this case? Please omit name

MD California

ANSWER—As long as any secreting cells remain, drainage will continue. In this case it is also necessary to determine roentgenographically whether there is now any osteomyelitis of the patella or a connection with the knee joint cavity. The latter may be demonstrated by means of injection of iodized poppy-seed oil. If these complications do not exist, the drainage tract should be curetted and then cauterized with surgical diathermy, phenol or Zenker's fluid. A compression bandage must be applied to prevent reaccumulation of the fluid. If no healing occurs subsequent to this treatment or if the foregoing complications exist, reoperation will be necessary. At this time, all secreting tissue should be removed if possible and those portions which cannot be excised should be curetted and cauterized

POSSIBLE SENSITIVITY TO LIVER EXTRACT

To the Editor—I have been treating a patient who has pernicious anemia with intramuscular injections of a concentrated liquid liver extract prepared by one of the leading pharmaceutical chemists. I have administered this preparation in the dosage recommended by the manufacturers and the results obtained have been excellent so far as improvement in the blood picture and the general nutrition and health of the patient are concerned. However about sixty days after the mentioned treatment the patient developed a severe and extremely obstinate case of urticaria. Nothing gives her relief except epinephrine and this for only a short time. Is it possible that the liver extract is responsible for the urticaria? Please advise me as to the toxic manifestations that might result from this treatment and if you can suggest anything to relieve this urticaria I will greatly appreciate it. I have eliminated all articles of diet that might have been causative factors. A change in residence has been of no avail. A complete physical examination including gastro-intestinal roentgenograms reveals nothing of a pathologic nature. Please omit name

MD North Carolina

ANSWER—In spite of its fairly wide use, reactions following liver treatment are rare. In one large clinic devoted to blood diseases reactions have occurred only twice in a large series of cases. 1 A man had asthma in addition to his anemia, and the first intravenous dose of liver extract was followed immediately by an attack of asthma before the second dose, however epinephrine was given and no reaction occurred. 2 In the second case cyanosis and collapse occurred immediately after injection. Urticaria however did not occur in either of these cases

In a case reported by Held and Goldbloom (*THE JOURNAL* April 25 1934 p 1361) generalized itching and redness with deep wheals like erythema nodosum followed the beginning of a series of intramuscular doses of liver extract. The skin lesions disappeared when the extract was withdrawn and reappeared when treatment was resumed. The same patient however was able to take cooked liver by mouth without difficulty. This is the only available published report. The condition is obviously rare

In the case under discussion urticaria developed sixty days after the beginning of liver treatment. The time interval is

pretty long, although the relief from epinephrine favors the theory of allergy as a cause of the trouble. The possibility is definite.

The treatment should be (1) to experiment with different brands of liver extract or (2) to substitute oral administration for intravenous or intramuscular administration, as in the reported case. If, later, the urticaria persists, the steps will be (1) to search and remove all foci of infection and (2) to consider the importance of dusts in the environment, making intradermal tests with extracts of such substances as silk floss, kapok, cottonseed, orris powder, animal danders, and pollens, since it is now recognized that urticaria and eczema result from exposure to foreign substances which may enter the system by way of the respiratory tract.

ICHTHYOSIS

To the Editor—While I was treating the son of a patient today she brought in an orphan she has been keeping for six years who has had a diagnosis of fish scale (or skin) dermatitis. He is now 9 years of age and every fall and winter when it is necessary to clothe him more fully he develops this condition which itches and changes the color of his skin to a grayish almost silver, appearance. The fish scale diagnosis was made probably from the way in which the skin (which is dry flaky and rough) assumes a cracked appearance resembling scales. This condition extends over the entire body except the face and hands which are of course exposed. The scales and itching also infest the hair. He has been under treatment with light probably ultraviolet and baths averaging sixteen a week (washing with soap and water and then applying some oil thought to be fish oil). Under this treatment the skin responds fairly well to assuming its normal appearance. He has been made much worse with cod liver oil so his adopted mother states. During the summer months he is entirely free from any itching or scales and wears but little clothing which has been the rule for the last six years. Now as to what I have observed of this young chap from first acquaintance. He is very attentive and is doing well in school. He seems to be quick tempered but not nervous. He sleeps well at night. His appetite is good. He had his tonsils out six years ago. His teeth are very good. He weighs 60 pounds (27 kg.) and is 59½ inches (152 cm.) tall (normal for a boy his age). His mother and father cannot be traced but from the history the mother was 14 years old and the father 15 when he was born. Would this cause any maldevelopment of the integument giving these symptoms and appearance? Would thyroid extract benefit this boy? Have you an idea as to the cause and how to treat the condition to eradicate it? Kindly omit name. M.D. Ohio.

ANSWER—This is a case of ichthyosis of moderate severity. The disease is often familial, but the youth of the parents had nothing to do with it as far as is known. The disease cannot be cured but may be mitigated greatly by proper bathing andunction, as is already being done. These cases are always worse in winter when the skin is dry. Borax or sodium carbonate may be added to the bath water. Immediately after the bath, while the skin is still moist, it must be anointed with oil of theobroma, petrolatum, or a mixture of olive oil 3 parts, glycerin 1 part and emulsion of hydrous wool fat 10 per cent in lime water or any of many other kinds of fat. Salicylic acid from 2 to 5 per cent may be added if it is thought necessary. On the face and hands, glycerin and sodium bichlorate may be used or the familiar glycerin 10 per cent in rose water.

Desiccated thyroid has been of benefit in ichthyosis. In the case under discussion it would seem unnecessary and had better be avoided unless the basal metabolism is low.

Residence in a warmer climate would mitigate the severity of the disease.

PIGMENTATION OF SKIN BY MERCURY CREAMS

To the Editor—In THE JOURNAL Nov. 3, 1934, in the answer to a query with reference to the effects of mercury impregnation on the hair it is stated that treatment for the removal of the mercury is very unsatisfactory. I have a patient who used a mercurial cream on her face, neck and arms for a number of years. She came to me about nine months ago with definite symptoms of advanced chronic mercurial poisoning. On examining the urine I found mercury present. After the patient discontinued the use of the cream and with the institution of eliminative treatment the metallic taste, foul breath and spongy gums cleared up and her health in general is improved but the slate color of the skin which appears only where the cream was used does not improve. I have prescribed sweat baths, potassium iodide and tonics and in addition she has tried blistering the skin and massage but the discoloration of the skin remains unimproved. What would you suggest and what is the prognosis? Kindly omit name. M.D. Pennsylvania.

ANSWER—The production of lasting staining of the skin by cosmetics containing mercury was reported by W. H. Goeckerman (A Peculiar Discoloration of the Skin THE JOURNAL, Aug. 19, 1922, p. 605). The pigment affected chiefly the eyelids, the nasolabial folds, the chin and the folds of the neck and looked as if the skin was dirty. On close inspection it was seen to be in black points in the follicular openings. Scrapings from this skin gave no information. Biopsy was not permitted. Treatment was but slowly helpful. Two per cent acetic acid

solution in water and from 0.5 to 1 per cent potassium cyanide in water were said by the patient to give definite improvement, showing how little credence can be given such reports, for, as was demonstrated later, the pigment was within the skin.

In a second report under the same heading (THE JOURNAL, Feb. 14, 1925, p. 506) Goeckerman reported thirteen more cases, from one of which he obtained a biopsy. The pigment was seen in the microscopic section scattered through all the layers of the skin, including the epidermis. Treating such a section with an iodine solution removed this pigment. Goeckerman recommends iodides internally or sodium thiosulphate.

J. B. Blashill (Pigmentation of the Face and Neck Due to Freckle Cream THE JOURNAL, June 18, 1932, p. 2200) reported another of these cases, tried several forms of treatment, and concluded that time was the chief hope for these sufferers.

External application can be of no avail. Iodine or sodium thiosulphate internally seems the only rational method of attack.

There are, of course, other possibilities. The pigment may be ordinary skin pigment increased by local irritation or chloasma secondary to the general poisoning with mercury, possibly due to liver damage. In this case, some improvement may be obtained by the persistent use of 30 per cent hydrogen dioxide 1 cc. and wool fat, 6 Gm., in sufficient petrolatum to make 10 Gm. This is to be applied to a small area once daily. If irritation results one should stop and wait for it to subside. The danger of increasing pigmentation by any irritating application must always be kept in mind. This treatment, of course, will not affect the mercury stain.

CHRONIC SINUS INFECTION

To the Editor—What is the accepted treatment of a chronic nasal and nasopharyngeal catarrh which condition is accompanied by an odor approaching that found in ozena? What is the status of nasal and nasopharyngeal irrigations in treatment of chronic infection of the paranasal sinuses? Please omit name. M.D. Iowa.

ANSWER—If the so-called catarrh is due to a chronic nasal sinus infection, the latter must be treated as such. In other words if there is obstruction to proper drainage, or if polyps are present, some type of operation on the sinuses will be necessary. If on the other hand there is an atrophic rhinitis or atrophic pharyngitis present, this must be treated in order to prevent the formation of abnormal secretion and its adherence to mucous membrane and then decomposition, the latter often giving rise to the foul odor of ozena. If the atrophic rhinitis or pharyngitis is present, a mild alkaline cleansing solution may be used. However, not only in this condition but in chronic infection of the nasal sinuses as well, douching is fraught with considerable danger to the ears unless certain precautions are observed, such as having an isotonic solution of a mild alkaline character, with the temperature of the fluid at slightly above body temperature, using but little pressure and having the mouth opened wide while the fluid is entering and leaving the nose. Douching, of course, is no cure but helps by removing secretions and, when ozena is present, often lessens the odor.

CONDYLOMA ACUMINATA

To the Editor—A primipara aged 20 was delivered by high forceps and a mild puerperal sepsis developed. Her temperature became normal but there is hypersensitiveness of the introitus and the vagina. There is a persistent leukorrhea from endocervicitis. The left Bartholin's gland gives a slight suggestion of chronic inflammation. Two growths developed one on each lateral wall of the vagina which look similar to hymenal tags except that they are red, bleed easily and are situated about 2 cm. proximal to the introitus but they do not seem to be hypersensitive. I have used 10 per cent silver nitrate to the cervix, sulphated bitumen glycerin tampons, gentian violet tampons and bismuth subnitrate tampons without results. The organism present on smears is an encapsulated diplococcus similar in size and shape to the pneumococcus. Hot douches have not relieved the hyperesthesia to any marked extent. The uterus is in second degree retroversion and is difficult to palpate or manipulate on account of pain. Would coagulation of the cervix and replacement of the uterus relieve the hyperesthesia? How best could the latter be done considering the pain? I would appreciate any suggestions in management of this case. Kindly omit name. M.D. Minnesota.

ANSWER—Naturally it is impossible to make a diagnosis from the description that has been sent of these lesions. There are several conditions that might cause the signs and symptoms. Condyloina acuminata and granulomas (excessive granulation) might be suggested. These granulomas should be removed by scraping and the bases should be cauterized. This usually cures the discharge, and the tenderness disappears in a short time. One should be conservative with electrical coagulation of the cervix as it is easily overdone. The treatment of condyloina acuminata was described in THE JOURNAL, January 12, page 137.

LIVER EXTRACT INTRAMUSCULARLY

To the Editor—In using liver extracts intramuscularly, I have heard that reactions are rare but they do occur implying general reactions. I presume But is there such a phenomenon as local tissue reaction? I have given these intramuscular injections in a considerable number of cases without any apparent disturbance except slight irritation on injection however the present patient, a rather stout person with very pronounced anemia, took the first seven doses without complaint except that a palpable lump seemed to remain After the eighth dose a hardened area the size of a hen's egg and a reddened area the size of the palm of the hand, developed The ninth dose produced an even greater area of reaction when this form of treatment had to be abandoned. Do you suppose that a change of the brand of material would be sufficient or would you place the patient on oral liver therapy? Please omit name

M D, New York

ANSWER.—It would be wise to switch to another brand of potent liver extract, and it is important not to reinject in the same area too frequently Different areas of the body should be chosen, so that no one area will be used more frequently than every third or fourth week. If the lump persists, a change to oral liver or desiccated hog stomach therapy is advisable

TRAVELING DURING PREGNANCY

To the Editor—A primipara four months pregnant is planning a three weeks vacation trip (her husband to do the driving) to Florida from Boston and back. Do you think it advisable and safe? Please omit name and town

M D Massachusetts

ANSWER.—Almost universally, pregnant women are cautioned against taking long automobile, train or boat trips. However with few exceptions there is in reality but little risk involved in traveling. Nevertheless, if a patient has bled one or more times during her present pregnancy it is best for her not to go far away from home. Likewise, if a woman has had one or more spontaneous miscarriages it is best for her to avoid long trips unless they are absolutely necessary. When a trip is planned, it is advisable to avoid traveling during the few days when the menstrual period would have occurred were the patient not pregnant. Nowadays with the remarkably smooth roads in most parts of the country and with the riding comfort of the modern automobile, most pregnant women may safely take long trips. It is much safer to tour after the fourth month than before that period.

TORSION OF SPERMATIC CORD

To the Editor—Can you give me any information on the following case? A Negro about 18 years old with fully developed external genital organs, has had his testicles retracted until the left one has returned into the abdomen and the right one has caught at the external abdominal ring. There has been no pain except for a short time in the right testicle due to pressure. The scrotum has entirely disappeared. From the time he first noticed any change, only about one week elapsed until the present condition was reached

D F STOUOR M D Geary Okla.

ANSWER.—Sudden changes in the external genitalia, such as mentioned in this query, can in all probability be best explained on the basis of torsion of the spermatic cord. This condition is acute in its onset and often is not recognized, so that the torsion is not released and atrophy of the testicle results, with or without retraction. However, attention may be called to the fact that torsion of the cord with atrophy of the testicle does not, as a rule, produce entire disappearance of the scrotum as stated here.

SODIUM BICARBONATE NOT A CATHARTIC

To the Editor—Please comment on the use of sodium bicarbonate as a cathartic given in such dose as a "heaping teaspoonful in a glass of hot water half an hour before meals. Is this an old remedy? Is there any harm in its continued use? Please suggest a few substitutes that may act similarly and as favorably

M D, Ind

ANSWER.—Sodium bicarbonate in a glassful of water is not a cathartic in the usual interpretation of the term, any more than a glass of water is. Nevertheless, cathartic action may be secured from either of these and no doubt, more certainly from the combination of the two. The latter should not be resorted to if the ingestion of a tumblerful of cold water suffices. If it does not, it would be preferable to employ a teaspoonful of sodium chloride in a glassful of hot water rather than the bicarbonate, as the latter may have a tendency to disturb the acid base equilibrium of the gastro-intestinal tract and even of the system. Indeed, it may act as a cathartic by disturbing normal digestive function.

Book Notices

X Ray Interpretation By H. Cecil H. Bull, M.A. M.B. M.R.C.P., I. Chytetan and H. H. Radcliffe. Royal Waterloo Hospital London. Cloth Price \$7. Pp. 382 with 280 illustrations. New York & London Oxford University Press 1935.

This has been written as an aid to clinical diagnosis, hence it devotes more space to common pathologic conditions than to the rare ones. Simple drawings and silhouettes were chosen to illustrate the text in the just belief that a sketch comes through with greater clearness and brings the writer in closer touch with the reader than any reproduction can do. The text is divided into chapters on the osseous system, brain, alimentary tract, cholecystography, chest, genito-urinary system, soft tissues, teeth and pregnancy. In each chapter a description of the normal appearance of the organ discussed is followed by a presentation of the most frequent pathologic conditions, including traumas. Valuable additions to the chapters on bones and articulations deal with ossification centers and their order of appearance. The orthodiagrammatic method of estimation of the size of the heart has not been described, sodium iodide is the only drug recommended for ascending pyelography, the use of thorium dioxide for visualization of the spleen should be discussed, although it frequently meets adverse criticism, Caldwell's, Grainger's and Waters-Waldron's positions for roentgenography of the sinuses deserve description, the use of occlusal films for recording the relationship of the teeth in the horizontal plane should be mentioned. These are minor omissions. The work is remarkably practical and comprehensive despite its conciseness. The author deserves credit for a simple, attractive presentation of his subject. The book should be enthusiastically received by the practitioner wishing to acquire an elementary knowledge of roentgen interpretation.

Praktische Diätetik mit über 500 Kochrezepten für diätetische Behandlung für Ärzte und Patienten Von Geh. Hofrat Dr. L. Roemheld Sanatorium Schloss Hornegg (Witbg.). Fourth edition of Praktischen diätetischen Kochbuchs von Dr. Curt Pariser. Cloth. Price 6.20 marks. Pp. 226. Leipzig: Fischers medizinische Buchhandlung 1935.

The author of this small book, the medical chief of a German sanatorium, urges physicians to use it in the daily adjustments of the feeding of their patients. The first part is devoted to a brief general discussion of diets for various ailments. The second part consists of recipes for a multitude of dishes. Theoretical considerations seem to be purposely avoided. Quantitative values are given practically only in connection with recipes. Caloric values, dextrose, fat and protein contents, mineral vitamin and fiber constituents are almost completely ignored. General discussion is mostly vague, many recommendations are antiquated and some contrary to present-day knowledge in nutrition. For example, various vegetable days, fruit days, milk days, oat days and rice days are still recommended in the diabetic regimen. All meats, vegetables and eggs, among other things, are completely unrestricted in the diabetic diets. As far as the recipes are concerned, it is difficult to imagine where their usefulness might lie. They seem unsuitable for either physician or chef. On the whole, this book seems to serve only the purpose of demonstrating the poor development of German dietetics.

The Nutritional Origin of Cancer By Edwin E. Ziegler, M.D. Paper Price \$2.50. Pp. 91. Boise, Idaho: The Author 1934.

The author has compiled a mass of statistical data designed to prove his thesis that the changing diet of man from an acid-forming diet to a base-forming diet explains the geographic incidence of cancer as well as the increase in the incidence of cancer. It is claimed that the effect of a prolonged base-forming diet is nutritional alkalosis with important adverse effects in the body. The author believes that certain European countries have a higher cancer death rate because they consume large quantities of alkaline foods, such as potatoes, whereas those countries which derive their calories chiefly from grain have the lower cancer death rates. For prophylaxis and treatment the author suggests the use of an acid-ash diet, hydrochloric acid and pepsin, the administration of predigested proteins, the administration of acid salts, and the parenteral injection of amino acids. It is obvious that the author accepts

unequivocally many statements in the literature that are open to challenge. For example, it is well known that the claimed difference in the incidence of cancer in noncivilized and in civilized communities has been demonstrated to be due to the fact that necropsy control and accurate records are naturally inferior in the less civilized countries.

The author does not present a true and clear concept of the normal acid-base balance of the blood and of the complicated regulative mechanism that keeps it within physiologic limits. As a matter of fact, the acid-base balance is only slightly disturbed even in severe diseases and almost not at all in the usual dietary differences of individuals during health. Thus Peters and Van Slyke state: "Hasselbalch demonstrated that changing from a high carbohydrate to a high protein diet caused the CO_2 capacity of the blood to fall about 3 volumes per cent. Blatherwick has analyzed the acid and base content of the ash of many foodstuffs and has classified them according to their acidifying or alkalinizing powers. He has also demonstrated that by selecting diets from foods belonging to one or other group the reaction of the urine may be altered in the desired direction. The adjusting ability of the kidneys, however, is so great that the products of normal metabolism cause hardly appreciable effects on the internal acid-base balance as indicated by the plasma bicarbonate content and pH ."

The author's assumption that a heavy protein diet is more acid forming is contradicted by Peters and Van Slyke (*Quantitative Clinical Chemistry*, p. 966), who state that the alkaline tide is most evident after a heavy protein meal and may fail to appear after one consisting predominantly of fat and carbohydrate.

On page 84 the author says: "Fever, starvation, incomplete surgical operation and other factors have been observed to cause regression of the cancer. The effect of these various agents is the production of a relative acidosis in the body." The regression of cancer under these circumstances is most questionable and, if it ever occurs, it is with extreme rarity. How an incomplete surgical operation can cause cancer regression and produce a relative acidosis is not clear. However the curious circumstance is that the author points to the acidosis of fever, starvation and incomplete surgical operation as a causative factor in tumor regression in the face of the thousands of patients who die of cancer in the presence of fever, starvation and because of incomplete surgical operation.

On page 85 the author makes the statement: "That the acidosis treatment is so spectacular emphasizes the fact that cancer is a deficiency disease." What evidence is there to support the spectacular nature of the acidosis treatment of cancer? A single isolated and highly questionable observation.

The excellent motives and high purpose of the author are beyond question, and on his interest and industry in collecting a vast array of data he is to be commended. The fundamental fallacy is obvious. In his eagerness and enthusiasm to prove his thesis he has selected the data that support his theory and omitted all evidence to the contrary. The work is uncritical and the conclusions therefore are unsound. It would be an accident indeed if a great truth should be discovered by considering only such data as seemed to support a theory without considering all phases of the question. The alkalosis theory of cancer causation and the acidosis treatment of cancer remain unproved theories.

Diättherapie der Lungentuberkulose. Von Dr. Max Gerson. Mit Röntgenbefunden und einem Röntgenkapitel von Dozent Dr. Felix Fleischner. Paper. Price 36 marks. Pp. 619 with 154 illustrations. Leipzig & Vienna: Franz Deuticke 1934.

This book, with a foreword by Felix Fleischner, contains an elaborate discussion of diet in the treatment of tuberculosis. Many pages are devoted to a theoretical discussion of acute and chronic infection, anaphylaxis, allergy, vitamins and minerals in the diet. Considerable attention is given to the importance of recognizing allergic conditions which may result in migraine, asthma and gastro-intestinal disturbance with the thought of discovering the exciting cause and removing it when the diet is responsible. Gerson's diet in the treatment of pulmonary tuberculosis which has become well known in various parts of the world, is outlined and discussed in considerable detail. Cases are reported representing various forms of tuber-

culosis that have been treated by the Gerson diet. This section of the book contains a large number of illustrations made from x-ray films of the chests of patients who have been treated by the dietetic method. It is interesting to note that diet has played an important part in the treatment of tuberculosis since the time of Hippocrates and that from time to time special diets have been advocated, not one of which has proved a panacea for the treatment of tuberculosis. It seems highly improbable that diet alone will ever suffice in the treatment of this disease. However, food is important in the treatment of any chronic disease but patients must be treated individually, since what may be definitely beneficial in one case may be harmful in another. Any physician treating tuberculosis will be helped by the information obtained from Gerson's book, provided he gives diet its proper evaluation and does not neglect other standard forms of treatment.

A Textbook of Nursing Technique: A Manual Used in the Associated Hospitals in the University of Minnesota School of Nursing. By Marion L. Vannier, R.N., and Barbara A. Thompson, R.N., B.S., Director of the Wisconsin Bureau of Nursing Education. Second edition. Cloth. Price \$2.50. Pp. 265 with illustrations. Minneapolis: University of Minnesota Press 1935.

In the preface of the first edition the authors stated that "the purpose of the manual is to assure accuracy in detail and to obviate the necessity of note-taking by the students during the presentation of the demonstrations by the instructor." Now, after four years of use, a revision has been made in an effort to clarify the steps in the procedures to alter technics as indicated in the light of new scientific knowledge, and to eliminate those procedures which do not easily fit into the schemes of different hospitals. The first half of the book is given over to a discussion of the elementary procedures, and the second half to advanced procedures. The latter includes an excellent chapter on problems related to communicable disease nursing technics. Also a copy of the record form used to evaluate student proficiency in nursing service is shown. An outline for the presentation of material for each procedure has been set up and consistently followed. This is complete, giving the purpose, the general instructions, the equipment needed, the steps in the procedure, and references. Throughout the entire book emphasis is given to the need for kindly consideration of the individual patient and to a careful use of supplies. A chart in the front of the book indicates that the principles and practice of nursing course is an integration of the basic general social, biologic and sanitary sciences directed and applied to the end that intelligent nursing service to individuals may result. While these procedures have been established specifically for their use in the associated hospitals of the University of Minnesota School of Nursing, they may very well serve as a guide to many other similar institutions. The joint authors, associated as they were for many years with the University of Minnesota School of Nursing, were intimately acquainted with the specific needs and in the preparation of this book have made a real contribution valuable to the student, the graduate nurse and the teacher. With increase in scientific knowledge, however, methods change and textbooks of this sort of necessity need frequent revision. Because there is so frequently a gap between the demonstrations of ideal procedures in the classroom and the practical daily performance by the students in the wards where supplies are often limited and time is insufficient, it might be well to supplement each procedure with suggestions of suitable adaptations based on the same fundamental principles but less elaborate than the original procedure. These situations may occur either within the hospital or within the private homes of patients. A manual of this nature is invaluable as an authority for the student nurse and as a reinforcement of classroom teaching and should be in the possession of every student nurse.

The B.C.G. Vaccine. By K. Neville Irvine, D.M., M.A., B.Ch., Hon. Physician to the Henley War Memorial Hospital. Cloth. Price \$1.75. Pp. 70. New York & London: Oxford University Press 1934.

This book presents a history of attempts to immunize against tuberculosis as well as the beliefs concerning immunity resulting from infection with tubercle bacilli in nature. The author has spent considerable time visiting clinics and laboratories where BCG has been studied and used in both animals and human beings. Moreover, he has made an extensive study of

the literature. The criticism of BCG on the ground that its virulence may return is cited. The author points out that among human beings who die of tuberculosis some time after the administration of BCG it is virtually impossible to prove with certainty whether in any given case the BCG has become virulent, since there are other possibilities, such as the individual having been infected with virulent human bacilli before the vaccine was administered or that infection may have occurred after the vaccine was administered.

The Lubeck disaster in which seventy-three infants died of tuberculosis after the administration of BCG, is discussed. Criminal proceedings were instituted and the final decision of the court was that the vaccine had been contaminated with virulent micro organisms. The director of the laboratory was sentenced to two years in prison and one of his co-workers to fifteen months for homicide and inflicting bodily injury through negligence. It is interesting to note that Petroff who followed the trial carefully, is of the opinion that the verdict was unjust and was based only on inference and not on facts.

Dr Irvine presents at some length the experimental work that has been attempted to produce immunity in animals and he calls attention to the statements of a number of workers who believe that the vaccine has a protective value for cattle. He closes the chapter on this subject with a statement to the effect that the results of work are most encouraging in cattle are not very striking in guinea pigs and provided no clue whatever in monkeys. However the work of Larson which showed that it has no practical effect on controlling tuberculosis in cattle, is not included.

Considerable space is given to the degree of immunity produced in man by the use of BCG. The author concludes this chapter by stating that the only conclusion that can be drawn is that statistical evidence on the subject is difficult to produce and that at the moment the results show that the BCG vaccine produces in man a definite but unmeasured degree of immunity. In his summary he points out that the virulence of BCG can be increased when suitably grown that it occasionally produces progressive tuberculosis in laboratory animals that it has not yet been proved to have caused progressive tuberculosis in man and that a definite degree of immunity is produced in cattle but that in other animals the results are not so clear. He states that a certain increase of immunity is produced in man but that it is impossible to say whether enough protection is produced to warrant the reorganization of the present scheme in England for dealing with tuberculosis. At this point it is interesting to note that England has not adopted BCG largely because fundamental methods of tuberculosis control consisting largely of finding the open case and breaking contact is so rapidly decreasing the morbidity and mortality that an uncertain method of immunization has not seemed to offer any advantage. Irvine is of the opinion that research should be begun in England to decide the degree of immunity produced in man. Doubtless many will take issue with this recommendation on the ground that already a sufficiently large number of persons in Europe and America (more than a million) have had BCG introduced into their bodies and that this should be a sufficiently large number from which to draw final conclusions as to the ultimate benefits or harm produced by BCG. Such conclusions cannot be drawn until after at least two decades, during which the most careful observations must be made on the present material.

Le diagnostic des phlébites des membres. Par M. Audier, chef de clinique médicale adjoint à la Faculté de médecine de Marseille. Travail de la clinique médicale du Professeur D. Olmer. Papier. Price 25 francs. Pp 179. Paris: G. Doin & Cie 1935.

This is a valuable addition to the existing French monographs of Ducuing and Delater on phlebitis. The recognition of the initial, preedematous stage is stressed. This stage may last from four to eight days before the fully developed stage of edema appears. The role of spasm, on both the arterial and the venous side, is emphasized. The author uses the McClure-Aldrich test extensively to diagnose an early phlebitis and to determine its termination. An excellent bibliography containing mostly French literature, is given. Being a treatise on diagnosis, nothing is added to the possible prevention and to the abortive treatment of this important malady.

Hughes' Practice of Medicine. Edited and revised by Burgess Gordon M.D. Associate Professor of Medicine Jefferson Medical College. With sections on Nervous and Mental Diseases by Harold D. Palmer M.D. Associate in Psychiatry Medical School University of Pennsylvania and on Diseases of the Skin by Vaughn C. Garner, M.D. Assistant Professor of Dermatology and Syphilology University of Pennsylvania. Fifteenth edition. Fabrikoid. Price \$5. Pp 808 with 61 illustrations. Philadelphia: P. Blakiston a Son & Company Inc. 1935.

Enology of a classic that enters its fifteenth edition is superfluous. Hence a review may be confined to pointing out a few omissions and offering certain suggestions. Insoluble bismuth preparations are not mentioned in the chapter on syphilis, according to the consensus, a continuous mode of treatment in early stages of syphilis is preferable to the interrupted one, many will take exception to the recommendation of a two months interval after the first course of injections, a clear outline of a combined treatment with arsenical and bismuth preparations is desirable. Tetrachloro ethylene, efficacious in the therapy of hookworm disease, should be mentioned. Hexylresorcinol deserves a place among drugs recommended for the treatment of ascarides, whipworms and pinworms, and carbon tetrachloride for elimination of the tapeworm. Brudzinski's test in meningitis is not described. The use of ammonium chloride and phosphoric acid in the treatment of lead poisoning deserves mention. A prescription for relief of eye symptoms in hay fever would be welcome. Carbarsone, chiniofon and vioform widely employed in the treatment of amebic dysentery, are not mentioned. Undoubtedly such and similar omissions are due to a laudible attitude of skepticism and conservatism of the new editor. The type has been reset, old illustrations have been replaced by new ones, and numerous additions have been made. The purpose of the book, viz, presenting the average picture of disease and its treatment in condensed form for the general practitioner has been accomplished in an admirable manner. The book fully deserves its popularity.

A Short Practice of Surgery. By Hamilton Bailey F.R.C.S. Surgeon Royal Northern Hospital London and R. J. McNeill Love M.B. F.R.C.S. Surgeon Royal Northern and Metropolitan Hospital London. Second edition. Cloth. Price 30s. Pp 987 with 731 illustrations. London: H. K. Lewis & Company Ltd. 1935.

This work is now presented in one volume and presents many of the advances in surgery since the publication of the first edition. The text follows the same plan as that used by most surgical manuals. The first six chapters consider a general survey of surgical principles as applicable to the body as a whole. The remaining chapters are devoted to the specific organs with their individual pathologic processes. This book should serve as an excellent introduction to surgery for the student and as a reference book for the general practitioner and is to be recommended for such purposes.

Orthopedics for the Teachers of Crippled Children. By Samuel W. Boorstein M.D. F.A.C.S. Cloth. Price \$1.50. Pp 120. New York: Aldem Publishing Company 1935.

This monograph was published for teachers and nurses of crippled children. It is based on a series of lectures on orthopedic surgery for a group who were teaching or preparing to teach physically handicapped children. The aim is to help teachers recognize the conditions they are going to encounter and to understand the psychology of the crippled child. The general aim of this series of lectures has been to present the major aspects of the more common conditions that cause physical handicaps. More particularly, the author has endeavored to show how the parent physician and teacher, by proper cooperation, can go far toward bringing the affected child to almost a normal physical state. He stresses the importance of properly orienting the mental attitude of the child and he outlines the means by which the teacher can become the most important single factor in the child's recovery. The author believes that the future of the child may depend on the teacher he encounters. Many cripples have made a success of life. Such examples as Alexander the Great, Milton, Byron, Helen Keller, Steinmetz and President Roosevelt forcibly illustrate that a brilliant personality may be housed in an asymmetrical body. The appendix contains a list of the cripples who attained success or fame despite the physical handicaps. One

feels certain that Charlie Chaplin would resent the reference to him in this category and Jimmy Durante would not like to be classed as "deformed and repulsive"

The following is a list of some of the better known handicapped who rose to fame

Abnormality in stature Charlie Chaplin Friedrich Hessing brace maker in Germany 1858 1918
Deformed and repulsive Napoleon emperor of France 1769 1821
Edgar Allan Poe, author and poet, 1809 1849
Hunchback Michael Angelo sculptor 1475 1564
Paralyzed Charles Darwin naturalist 1809 1849 Charles Dickens author 1812 1870 Leonardo da Vinci artist died in 1519 Franklin D Roosevelt, President of the United States Philip Snowden chancellor of the exchequer of England
Lame because of dislocation of hip Victor Hugo author 1802 1885
Maimed upper extremity Wilhelm II ex kaiser of Germany
Club-Foot Lord Byron poet 1788 1824 Talleyrand diplomat 1754 1838

With reference to the proper attitude toward braces, the author quotes Dr Frank D Dickson of Kansas City, as follows

To those who need help and support for impaired limbs and backs, braces are true friends and helpmates but, as with friends, they must be carefully chosen and cherished Neither friendship nor braces can be expected to stand up under the demands of life if poorly chosen and treated with neglect"

Surgical Applied Anatomy By Sir Frederick Treves Bart Ninth edition revised by C C Choyce CMG CBE BSc Professor of Surgery University of London Cloth Price \$4 Pp 720 with 174 illustrations Philadelphia Lea & Febiger 1934

This small volume, originally written fifty years ago and now revised by Prof C C Choyce, presents surgical anatomy in practical and readable form It divides the body into six regions—head and neck, thorax, upper extremity, lower extremity, abdomen and pelvis, and spine and spinal cord—and each is amply covered from the standpoint of the general surgeon as well as the various surgical specialties Surgery of the blood vessels, which deals with ligations, abnormalities and collateral circulation, is omitted for the sake of brevity The work is concise but written clearly and simply, though not abundantly illustrated Its survival as well as its popularity is indicative of its usefulness as a textbook to the senior student and "to the practitioners whose memory of their dissecting room work is growing a little gray"

Practical Neurological Diagnosis with Special Reference to the Problems of Neurosurgery By R Glen Spurling MD Assistant Clinical Professor of Surgery (in Charge of Neurosurgery) University of Louisville School of Medicine Cloth Price \$4 Pp 233 with 99 illustrations Springfield Illinois & Baltimore Charles C Thomas 1935

The author discusses in three parts the fundamentals of neurologic diagnosis The first part (145 pages) covers the neurologic diagnosis in general examination of the cranial nerves, reflexes, brain and spinal cord (the peripheral nerves are omitted) The second part (about thirty pages) is devoted to the cerebrospinal fluid, and in the third part (forty-four pages) he deals with roentgen diagnosis, including encephalography and ventriculography The review is brief but clear so that a beginner can derive full benefit from the well written text and good illustrations many borrowed Anatomic and physiologic considerations have not been neglected, and only necessary, well established facts have been recorded Spurling's modest textbook will undoubtedly be of great benefit to students and practitioners in general

A New Deal in Liquor A Plea for Dilution By Wendell Henderson Professor of Applied Physiology Yale University Also a Reprinting of an Inquiry into the Effects of Ardent Spirits upon the Human Body and Mind By Dr Benjamin Rush Cloth Price \$2 Pp 239 with 5 illustrations Garden City N Y Doubleday Doran & Company Inc 1934

This is a historical physiologic and sociological monograph on the alcohol problem in society, by a physiologist well known to American physicians for his investigations, especially on the heart, circulation and respiration As indicated by the subtitle, Dr Henderson's solution for the liquor problem is dilution, that is to discourage, by education and appropriate legislation, the consumption of beverages with an alcohol content higher than 15 or 20 per cent As to this, the author is on the solid ground of established physiologic and medical facts,

but he ends his discussion with the pessimistic prophecy "that our future in respect to alcohol will be essentially like our past", that is, periodic oscillations between the extremes of prohibition and unrestrained indulgence in ardent spirits The monograph is both readable and reliable While intended primarily for laymen it contains matters of much interest to physicians, among which is a reprint of the classic essay by Dr Benjamin Rush "The Effects of Ardent Spirits on the Human Body and Mind" (1814)

Medicolegal

Dental Practice Acts Legislative Prohibition of "Bait Advertising" Upheld—The plaintiff, a licensed dentist, sought to restrain the Oregon state board of dental examiners from revoking his license on the ground of unprofessional conduct The trial court entered a decree of dismissal and the plaintiff appealed to the Supreme Court of Oregon

The provision of the dental practice act under which the board proposed to revoke the plaintiff's license defined "unprofessional conduct" as follows

Advertising professional superiority or the performance of professional services in a superior manner advertising prices for professional service advertising by means of large display glaring light signs or containing as a part thereof the representation of a tooth teeth bridge work or any portion of the human head employing or making use of advertising solicitors or free publicity press agents or advertising any free dental work or free examination or advertising to guarantee any dental service or to perform any dental operation painlessly (Laws of 1933, chapter 166)

The plaintiff contended that the foregoing provision was unconstitutional

A person who aspires to treat human ailments and thereby invites the confidence of the public to an exceptional degree, said the Supreme Court of Oregon, should be compelled to submit to such regulations as will guard the public as far as possible against fraud and deception The extent to which the police power may be exercised depends largely on the manner and degree in which the public welfare is involved Courts, with good reasons, have refused to define police power, for to do so might thus limit it to the detriment of the public welfare Regulation of professional conduct deemed unduly drastic ten years ago might well be considered reasonable under present conditions The necessity for legislation rests primarily on the judgment of the legislature. It is only when a legislative act clearly appears arbitrary, capricious, and without reasonable relation to the object sought to be attained that courts will interfere. The challenged statutory regulations were enacted, in the opinion of the court, by the state in the proper exercise of its police power and therefore do not violate the due process clause of the federal and the state constitutions The statute has for its purpose the elevation of the standards of the dental profession and the prevention of advertising of a character ordinarily used by unscrupulous practitioners to deceive or mislead the public. The fact that the legislation here involved applies only to dentists does not constitute it class legislation and therefore unconstitutional The state has the power to deal with each profession as a class and in doing so does not violate the equal protection clause of the constitution The Supreme Court of Oregon affirmed the decree of the lower court whereupon the plaintiff appealed to the Supreme Court of the United States

The plaintiff was not entitled to complain of interference with any contracts he had made for display signs and for advertisements in newspapers, said the United States Supreme Court His contracts were necessarily subject to the reasonable exercise of the protective power of the state Nor could the plaintiff object because the particular regulation was limited to dentists The state was not bound to deal alike with all professional classes or to strike at all evils at the same time or in the same way It could deal with the different professions according to the needs of the public in relation to each That the state may regulate the practice of dentistry, prescribing the qualifications that are reasonably necessary, and to that end may require licenses and establish supervision by an administrative board, is not open to dispute. The state may thus afford protection

against ignorance, incapacity and imposition. A state may deny to corporations the right to practice, insisting on the personal obligations of individuals (*State Board of Dental Examiners v. Miller*, 90 Colo 193, 8 P (2d) 699, *Miller v. State Board of Dental Examiners* 287 U S 563, 53 S Ct 6). A state may prohibit advertising that tends to mislead the public (*Dr Bloom Dentist, Inc v. Cruise*, 259 N Y 358, 182 N E 16, *Id.*, 288 U S 588, 53 S Ct 320).

The plaintiff insisted, however, that the statute in question prohibits advertising of the character described although it may be truthful. He contended that the superiority he advertised existed in fact, that by his method he was able to offer low prices and to render a beneficial public service contributing to the comfort and happiness of a large number of persons. But said the United States Supreme Court, the state court defined the policy of the statute. It said that while, in itself, there was nothing harmful in merely advertising prices for dental work or in displaying glaring signs illustrating teeth and bridge work, it could not be doubted that practitioners who were not willing to abide by the ethics of their profession often resorted to such advertising methods "to lure the credulous and ignorant members of the public to their offices for the purpose of fleecing them." The legislature was aiming at "bait advertising." "Inducing patronage," said the Oregon court, "by representations of 'painless dentistry,' 'professional superiority,' free examinations' and 'guaranteed dental work' was as a general rule 'the practice of the charlatan and the quack to entice the public'." The state is authorized continued the United States Supreme Court, to estimate the blifeful effects of such methods and to put a stop to them. The legislature was not dealing with traders in commodities but with the vital interest of public health, and with a profession treating bodily ills and demanding different standards of conduct from those which are traditional in the competition of the market place. The community is concerned with the maintenance of professional standards which will insure not only competence in individual practitioners, but protection against those who would prey on a public peculiarly susceptible to imposition through alluring promises of physical relief. The community is concerned in providing safeguards not only against deception but against practices which would tend to demoralize the profession by forcing its members into an unseemly rivalry which would enlarge the opportunities of the least scrupulous. What is generally called the "ethics" of the profession is but the consensus of expert opinion as to the necessity of such standards.

It is no answer to say, as regards the plaintiff's claim of right to advertise his "professional superiority" or his "performance of professional services in a superior manner," that he is telling the truth. In framing its policy the legislature was not bound to provide for determinations of the relative proficiency of particular practitioners. The legislature was entitled to consider the general effects of the practices which it described and, if these effects were injurious in facilitating unwarranted and misleading claims, to counteract them by a general rule even though in particular instances there might be no actual deception or misstatement. The Supreme Court of the United States, therefore, affirmed the judgment of the Supreme Court of Oregon—*Semler v. Oregon State Board of Dental Examiners (Ore.)* 34 P (2d) 311 55 S Ct 570.

Hospitals, Charitable Charitable Status Determinable by Court, Not by Jury—The appellee, while a patient at the City Hospital of Akron sustained a leg burn which he attributed to the negligence of hospital employees in applying a hot water bottle. He sued the hospital and obtained judgment in the trial court, from which the hospital appealed to the court of appeals of Ohio, Summit County.

If the trustees of a public charitable hospital in Ohio exercise reasonable care in selecting and retaining competent physicians, nurses employees and servants, the hospital is not liable to a patient for damages resulting from the negligence and incompetence of those so selected and retained. A careful review of all the evidence in the case convinced the court of appeals that the hospital was a public charitable institution and was not negligent in the selection or retention of the nurse to whose negligence was attributed the patient's injuries. The trial court erred in not granting the motion of the hospital at

the close of all the evidence for a judgment in its favor. As a general rule the question of whether a hospital is a charitable institution or not is not a question of fact that is required to be submitted to a jury but is one of law to be determined by the court—*City Hospital of Akron v. Lewis (Ohio)*, 192 N E 140.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Value of Sternal Puncture in Clinical Hematology—During the last year Reich employed sternal puncture as a routine procedure in all cases of blood dyscrasias seen in consultation. Sternal puncture is valuable in differentiating the various types of anemia, in establishing the diagnosis of leukemia in doubtful cases and in differentiating aleukemic lymphatic leukemia from agranulocytosis. In one instance it was possible to see tumor cells in the sternal marrow. This method of investigation does much more for the hematologist, however than aid him in his diagnosis. It gives him an insight into the fundamental processes underlying his observations on the peripheral blood and opens new avenues of clinical research. It is now possible to study the changes in the bone marrow almost as frequently as those in the peripheral blood and to observe the direct effect of therapy on the formative tissue.

Effective Treatment of Arachnidism by Calcium Salts—Gilbert and Stewart review the therapeutic measures in the treatment of arachnidism and present five cases in which they found that intravenous injections of a 10 per cent solution of calcium chloride gave instantaneous and prolonged relief of the pain and at the same time produced immediate relaxation of the muscle spasm so commonly seen in these patients. However, calcium chloride is not given without considerable danger as to its necrotic action on tissue outside a vein. This danger is greatly magnified when its use is attempted in the treatment of children. Therefore, calcium gluconate (10 cc of a 10 per cent solution, intravenously), which does not have this objectionable feature was used and found to produce as good results as the calcium chloride. The intramuscular route advisable for children, gave relief within a minutes time. Calcium lactate orally was ineffective probably because of its incomplete and slow absorption. The active principle of the venom has not been definitely determined, but it is generally accepted that the toxin directly stimulates the myoneural junctions or that it acts on the nerve endings as calcium apparently depresses the neuromuscular junctions in muscle or is depressant to most nervous and muscular functions.

Hypoproteinemic Nephrosis and Its Treatment with Acacia—Barach and Boyd cite two cases of chronic lipid nephrosis, one in a woman, aged 20, and one in a boy, aged 4. Neither patient showed evidences of improvement until acacia was given intravenously. One patient received eleven injections, totaling 295 Gm of acacia, the other required only one injection to start the diuresis and bring about a clinical recovery. In both patients there was a striking diuresis following the injections of acacia. Systemic reactions from the injections were mild and without ill effects. The authors employed a 30 per cent solution of acacia with a 4.5 per cent solution of sodium chloride, which should be a clear pale yellow. Darker solutions may cause reactions and should be avoided. This acacia solution is diluted with physiologic solution of sodium chloride to a total volume of 500 cc and injected slowly.

Extrapleural Thoracoplasty in Pulmonary Tuberculosis—Head gives the early results in fifty thoracoplasties in which different types of operation were used. Fifty-six per cent of the cases are arrested or apparently arrested, 18 per cent are markedly improved and with a favorable prognosis, 18 per cent are improved, 2 per cent are unimproved, 2 per cent of the patients died from the operation and 6 per cent died later of causes unconnected with the procedure. The results in the different groups of cases were in proportion to the completeness of the collapse of the diseased area of the lung. He suggests that, if thoracoplasty is used at the proper time and if a complete collapse of the disease is obtained the indications for the operation will be considerably extended and the results markedly improved.

Gastric Acidity in Pulmonary Tuberculosis—Gray and Melnick base their conclusions on gastric acidity in pulmonary tuberculosis on a study of fifty tuberculous patients between the ages of 20 and 30 years. 1 In young persons pulmonary tuberculosis produces gastric hypo acidity in approximately one third and anacidity in one fourth of the patients within a period of from one to four years. Approximately one half of the number show a normal acidity at all times. 2 In male patients a little more than half show normal acidity through a six-year period of disease. Approximately one third show a decrease or absence of acid. 3 In the female patient normal acidity is present in one third, with a decrease or an absence of acid values in two thirds. There is a definite tendency in the women toward a decrease in acid values. 4 The gastric contents show tubercle bacilli in the majority of these young adults. As the acid figures decrease, tubercle bacilli are found more frequently in the contents of the stomach. 5 Gastric symptoms are somewhat more frequent in the female than in the male patient and usually start at an earlier period.

The Alternately Expanding and Contracting Tuberculous Cavity—Korol believes that the condition of the draining bronchus has a determining influence on the size and progress of the cavity. A temporary narrowing of the bronchus will lead to sudden enlargement of the cavity, a return of the lumen to its former size will result in rapid shrinking of the cavity. The narrowing of the draining bronchus may be temporary, owing to catarrhal swelling, granulation tissue, foreign body, caseous material, tenacious sputum or a blood clot. Cavities have thus been seen to reopen or to enlarge following a head cold or an attack of grip. After the bronchial passage has returned to normal the cavity shrinks rapidly. A case is described in which the upper lobe of the right bronchus was partly occluded by a blood clot, which was visualized on the roentgenogram. An enlargement of the cavity in the right upper lobe occurred. After the discharge of the clot the cavity promptly returned to its original size.

Zinc Peroxide in Treatment of Micro-Aerophilic and Anaerobic Infections—Meleney discusses the clinical course of six cases of chronic infection of the abdominal wall, characterized by a slowly developing ulceration without gangrene but with extensive undermining of the skin by the liquefaction of the subcutaneous tissue and the formation of the deep sinuses. Apparently the essential causative organism in these infections was a micro-aerophilic hemolytic streptococcus, preferring anaerobic environment and in most cases found only by anaerobic methods of cultivation. Zinc peroxide in three cases changed the course of the disease favorably and was followed by relatively rapid resolution of the process. In two of these cases, following the use of zinc peroxide, the organisms apparently underwent a striking change, losing their hemolytic and their anaerobic properties. In the laboratory culture mediums, the micro-aerophilic hemolytic streptococci from these cases were rapidly killed when zinc peroxide was added while their aerobic,

nonhemolytic progeny grew luxuriantly. Zinc peroxide has been found to inhibit the growth and kill other micro-aerophilic and anaerobic organisms both in the test tube and in infected wounds consistently enough to permit the author to advise its use more extensively in these infections. In searching the literature the author has not been able to find an adequate description of the clinical course or the bacteriologic features of this disease and he assumes that it is relatively rare, but its chronicity and its severity are indicative of its importance. The disease must not be confused with the acute gangrene of the skin as represented by hemolytic streptococcus gangrene or with the chronic progressive postoperative gangrene of the synergistic type. It may be easily differentiated from these both clinically and bacteriologically if careful consideration is given to the characteristic features of these diseases.

Parathyroidectomy for Raynaud's Disease and Scleroderma—Bernheim and Garlock are of the opinion that disturbances in calcium metabolism are factors in the development of Raynaud's disease and other vasospastic conditions. How disturbances in calcium metabolism produce the manifestations seen in vasospastic conditions is not clear. One function of the parathyroids is to maintain a constant serum calcium level. If patients suffering from vasospastic conditions are given an adequate calcium regimen, many of them will respond favorably. That is, there will be a marked amelioration of symptoms which have been due primarily to vasospasm. When improvement does not take place in spite of prolonged treatment, they feel that a change of a more or less permanent nature has taken place in the parathyroids and that in such instances removal of two or more parathyroid bodies is indicated. Six patients were subjected to parathyroidectomy. Three cases presented generalized scleroderma with moderately severe Raynaud's manifestations in the hands and feet, one advanced sclerodactylia with symptoms of vasospasm of the hands and feet and two Raynaud's disease uncomplicated by changes of the skin. Following operation a dramatic relief of symptoms due to vasospasm was noted in each instance. The relief of pain and the change in color of the involved extremities to normal occurred within about twenty-four hours. The most astonishing results were noted in the cases of uncomplicated Raynaud's disease. Rapid improvement was noted in the oscillometric determinations both as to range of oscillation and as to degree of spasm. Improvement also in surface temperature was evident. After a lapse of from three months to one year, these patients have continued to do well. Cases of scleroderma continue to improve up to a certain point and then remain stationary. The involved skin becomes noticeably softer, wrinkles return and finger function improves. In the first three cases, two parathyroids were removed. In the other three cases, total excision of two glands and subtotal removal of a third was performed, after isolation of all four parathyroids. In every case the glands presented hypertrophy of varying degrees. Those showing the greatest enlargement were removed. The gland removed from the patient with extensive scleroderma presented an acute parathyroiditis with pronounced infiltration of polymorphonuclear leukocytes. The cases of uncomplicated Raynaud's disease showed marked hyperplasia. The remaining cases failed to show any abnormalities. It is important to isolate all four parathyroids and to exclude the presence of an adenoma before any gland is removed.

Surgical Treatment of Rectal Prolapse—Salvin outlines a method of treating prolapse of the rectum. With the patient in the high Trendelenburg position, a left paramedian abdominal incision was extended from the symphysis to the level of the umbilicus. The uterus was elevated and fixed to the anterior abdominal wall. The recto-uterine peritoneal reflection was incised transversely, two lateral longitudinal incisions extending through the rectal serosa into the mesorectum. The rectum was dissected from the vaginal septum and the sacral excavation, and its perineal and sacral flexures were mobilized. The rectum was attached with Pagenstecher sutures to the left lateral posterior aspect of the ventrofixed uterus, well up and across to the right side. A few more sutures fixed the middle part of the sigmoid to the anterior abdominal wall, the lower part of the sigmoid for a distance of 3 or 4 inches being left entirely free of sutures. This was done in order to prevent

linking and development of obstruction at the site of fixation of the rectum to the abdominal wall and to form a defensive barrier against the effect of too great peristaltic activity on the transplanted rectum. The bowels were kept constipated seven days with deodorized tincture of opium, when an enema of 5 ounces (150 cc.) of olive oil was given for two days, resulting in a natural movement. Thereafter feces passed normally every day. The sphincters function perfectly, with no involuntary escape of flatus. Normal intestinal function has been restored. The operation presents definite advantages. The low position of the pouch of Douglas is corrected. The prolapsed rectum is elevated and fixed on its entire length to the anterior abdominal wall, thus preventing the possibility of forming a new protrusion in the anterior wall of the rectum. There is no danger of coming in contact with the ureters or injuring the internal iliac vessels. The method of suturing the transplanted intestine to the anterior wall prevents kinking and angulation and possible formation of later intestinal obstruction.

Ambulatory Method of Treating Fractures of Patella
—Anderson believes that many advantages follow his method of treating fractures of the patella, which permits immediate ambulation. The fact of walking is most pertinent to injuries of this structure, because the musculature of the knee is more susceptible to atrophy than that of other joints. The method is founded on two principles: (1) reduction by the application of skeletal traction to the upper patellar fragment and (2) immobilization through the agency of a case in which are incorporated both this superior transfixion and a distal anchoring pin passed through the upper end of the tibia.

A Study of Urticaria.—Stokes and his associates discuss urticaria as a disease of complex rather than single causation, with groups of predisposing and exciting causes and with special consideration of the psychogenic component. The weak spot in an otherwise fairly complete theoretical chain is at the cortical end, and suggestions for joint investigations are made. In their 100 cases there was a marked familial and hereditary urticariogenic background in 60 per cent. There was a distinct predisposition to urticaria as such in 28 per cent, in addition to the other elements of the allergic (atopic)-neurogenic background. Cutaneous infections were frequent (50 per cent), but of unproved etiologic significance. Constipation was the one gastro intestinal symptom of major importance. Subjective disturbances of other kinds, including symptoms of disturbances of the gallbladder, were present in only 18 per cent of the cases. Abnormality of the biliary tract occurred in about 50 per cent and hypochlorhydria or achlorhydria occurred in 45 per cent of other groups investigated for the condition. Focal and intercurrent infections have undoubted etiologic importance, the precise weight of which is undetermined. Removal of a focus may or may not help. Urticaria may follow a focal flare-up or a fresh infection. Positive reactions to scratch tests for allergic conditions were obtained in 64 per cent of the cases. Atopic (multiple) sensitivity was observed. The most common allergic concomitants of urticaria were hay fever and vasomotor rhinitis. With regard to the possible causal factors, the largest proportion of the cases exhibited two causes other than the psychogenic, and 75 per cent showed from one to three

causes. An atopic and allergic history was most important in the cases due to food allergy and to psychoneurogenic factors. The combination of a psychogenic background with a food excitant appeared in 25 per cent and in seven cases was the sole etiologic factor determined. Abnormal psychoneurogenic elements appeared in the background in 83 per cent of the cases of urticaria, as compared with 24 per cent in a control series of psoriasis, acne and impetigo, but a psychoneurogenic cause operated alone in only 12 per cent. The principal psychogenic elements are the tension make-up, neuroticism, the worry habit, shocks, family troubles and finance. Sex disturbance was of minor significance. The urticariogenic psychoneurogenic background lies in a personality type rather than in external impinging circumstances. The therapeutic methods employed were the use of an acid calcium regimen, nonspecific desensitizations, psychotherapy, actinotherapy, dietotherapy and occasionally the administration of atropine and ephedrine. Of the known outcomes, 60 per cent were good ("cures"), improvement occurred in 34 per cent of the patients, and failures in 6 per cent. The exclusion of substances to which the patient gave a positive reaction (scratch tests) and an elimination diet were unsuccessful as therapeutic measures. Attention to several factors in a case rather than to one alone increases the proportion of good results. An unknown proportion of cases of urticaria is self cured. Dogmatic assertion as to sole causes is therefore to be deprecated.

Incidence of Bacteremia in Pneumonias.—Bullowa and Wilcox believe that the recovery of pneumococci from the blood stream during the course of pneumococcal pneumonia may be prima facie evidence that the protective mechanism which prevents or overcomes bacteremia is at least partially in abeyance. Whether recovery or death will be the outcome in pneumococcal pneumonia depends to a great extent on whether the protective mechanism alone, or aided by serum, suffices to prevent an increase in the number of organisms or to clear the blood of pneumococci after it has been invaded. In most cases, positive blood cultures give unequivocal evidence of the type of pneumococcus responsible for the illness and the disappearance of bacteremia in response to treatment may be a real measure of efficient specific therapy. In cases in which invasion of the blood continues in spite of therapy, the illness is almost uniformly fatal. The authors list the incidence of bacteremia in connection with the fatality rate for different types of pneumococcal pneumonia in a series of 725 cases due to a single type, occurring over a period of five years. The percentage of invasion of the blood differs for the different types, though in the main the percentages of invasiveness and mortality are approximately the same. The importance of (1) differentiating the types formerly included as group IV or the α group and (2) of typing individual cases for prognosis and eventual treatment, when specific treatment is available, is manifest. Only 3 per cent of pneumococcal pneumonias escape classification at the present time, when typing is carried from I to XXXII (Cooper). The variation in percentage of invasion and fatality from year

to year in different pneumococcus types is evidence of the variations that are encountered from season to season and shows the necessity of extending the testing of any proposed curative substance over a period of several years.

Leukemic Sinus Reticulosis with Intestinal Obstruction—Hanning and his associates cite a case of acute monocytic leukemia in a young woman with localized mucosal and submucosal reticulosis in the rectal wall which assumed the proportions of a tumor. The tumor produced complete intestinal obstruction, clinically the case exactly simulated carcinoma of the rectum with intestinal obstruction. The venous sinuses of the spleen and of the bone marrow and the lymph sinuses of the spleen and of the lymph glands probably are lined by differentiated reticular cells. These cells are similar to the Kupffer cells of the liver. Like the Kupffer cells, they are entirely different from the endothelial cells lining the ordinary blood and lymph channels. The term 'reticulo-endotheliosis' applied to monocytic leukemia does not elucidate the fact that the endothelial cells lining the ordinary blood and lymph vessels have nothing to do with the process. Neither does it attempt to distinguish between true reticulum and sinus reticulum (reticulo-endothelium). Monocytic leukemia is probably a sinus reticulosis whereas myeloid and lymphoid leukemia are probably true reticuloses. There are good grounds for the conception that leukemia is a malignant neoplastic process. Malignant processes and neoplasia are closely associated in the authors' minds with infiltration and with tumor formation. Specific localization with tumor formation is apparently infrequent in leukemic sinus reticulosis (monocytic leukemia).

Toxemia of Pregnancy—Herrick and Tillman report on 594 cases of toxemia of pregnancy that have been studied by internists during the period of toxic gestation and during a follow-up period averaging five and six-tenths years with extremes of one and twenty-two years. The death rate in this group was 27 per cent based on the mortality figures for women in general between the ages of 20 and 45 years in the city of New York which is 0.4 per cent. The mortality in this group was 157 per cent. Of the deaths 80 per cent were from causes within the cardiovascularrenal field. From a medical point of view the cases fall into two groups. The first and smaller is associated with a latent or manifest primary glomerulonephritis, and the second, and larger, with hypertensive cardiovascular disease. These differ in their clinical manifestations during the toxemia and in the follow up period and also in the prognosis and treatment. More than half of the survivors of toxic pregnancy show symptoms and signs of one or the other of these conditions within three years. Eleven cases have come to necropsy. In these the pathologists, independently of the clinic have described two types of disease. In four cases there were changes typical of chronic glomerulonephritis, and in seven there were changes characteristic of cardiovascular disease with hypertension. The clinical and pathologic evidence suggests a continuous chain of events in cases of toxemia with cardiovascular sequels. The vascular damage of the acute phase of the disease may not be repaired but may become permanent leading in at least half the cases to the manifestations of hyperpneis in the follow-up period and to ultimate disclosure at necropsy of characteristics of this generalized disease of the arterial system which ends in cardiac failure, apoplexy or renal failure through narrowing of the vascular channels supplying the kidneys.

The Arthritides and Colon Therapy J Gutman Brooklyn.—p 162

Prevention of Rheumatism—Bjorkman offers some observations on prophylactic measures against the ravages of this disease. He submits rheumatism as an example of how small

and insidious disorders in a muscle or a joint may with irresistible tenacity gradually increase in severity and finally completely wreck a vigorous body and doom it to years of invalidism. He believes that hypothermia is the beginning of this disease, which often completely destroys the main bearings of the locomotor apparatus. Rheumatoid arthritis, osteoarthritis and their subsequent degenerative stages, proliferative, climacteric and senile types, myositis or fibrositis are but names for different stages and complications of the same disease, which begins with the overlooked and untreated effects of partial or general refrigeration of the body. Rheumatism and its many consequences are pathologic conditions chiefly encountered among people exposed to cold windy and wet weather, but people living in the tropical or subtropical belt are by no means exempt. Sudden drops in the temperature accompanied by wind and wet during the rainy season explain the frequent incidence of rheumatism in these countries. The author believes that massage, in the prevention of the pathologic fibrous organization in the human locomotor apparatus resultant on exposure to inclement weather and wind, is the only means by which cold edema and its organized by-products can be removed. Rheumatism is not encountered among the better situated classes of people in Europe or America, who as a matter of personal hygiene indulge almost daily in massage. The author concludes that massage is a true prophylactic agent against this devastating disease. It is a fact not to be overlooked, that the popular steam baths and massage of Sweden are important factors in almost completely confining rheumatism to the working classes, who use these baths less frequently than others.

Gonococcal Tenosynovitis of the Hand—Murray and Morgan discuss a case of gonorrheal tenosynovitis, which occurred six days after the first appearance of an acute gonorrheal urethritis. They believe that at the time of the patient's slight injury of the hand the man was suffering from a gonococcal bacteremia. Trauma produced a minor resistant focus, with localization of the organism at that point. The authors believe that this type of tenosynovitis occurs with greater frequency than is generally recognized. The probability of the organism being the gonococcus was recognized before operation. The presence of a frank suppurative tenosynovitis determined the course of treatment. While a gonorrheal infection of the tendon sheaths may occur without suppuration and as such may be treated conservatively, the presence of pus justifies incision and drainage. The result of this method of treatment was good and the patient now suffers but little disability.

Primary Thrombosis of the Axillary Vein—Ballon presents a case of primary thrombosis of the axillary vein in which the presence of boils previous to the development of the

thrombosis may have been a complicating factor. The incision of the abscess on the left arm may have been a contributing or predisposing factor. All conditions that may produce mechanical compression of the axillary vein must first be excluded before a diagnosis of primary thrombosis of the axillary vein is made. Complete roentgen studies were made in the case reported, and such conditions as tumor, aneurysm, fracture, cervical rib, tuberculosis and pleurisy were excluded.

Preoperative Administration of Extract of Pregnancy Urine—Hamblen studied the ovaries and the endometrium of twenty-four patients nine with known normal menstrual cycles, eleven with hyperplasia of the endometrium and four with amenorrhea. A commercial anterior pituitary luteinizing extract of pregnancy urine was used. The single subcutaneous injection has varied from 100 to 400 rat units. The frequency of dosage has varied from one to four times daily. The total dosage has ranged from 800 to 8,200 rat units. The duration of injections was from three to thirteen days. The time elapsing from the last injection to the laparotomy varied from one to fourteen days. Injections were given on the second to the thirty-second day of the menstrual cycle. Laparotomy was performed on the eleventh to the fortieth day of the cycle. At the time of laparotomy a careful gross study of both ovaries was recorded including the size of the ovaries the presence and relative number of small cysts and the presence or absence of recent or old corpora lutea. Endometrial specimens were obtained before the administration of the extract and after the injections of extract at the same time as the ovarian specimens. Anterior pituitary luteinizing extract does not affect primordial or early follicles and it acts primarily on maturing and mature ones increasing the degenerative changes commonly observed and probably producing cystic degeneration. The response in the younger age group (immaturity) is different from that of the older age group (maturity) of patients with hyperplasia. Recent corpora lutea are produced apparently in the latter group by injections of anterior pituitary luteinizing extract. Hemor-

rhage into or about follicles constituted an unimportant observation. Endometrial changes were produced in a single instance.

Anterior Pituitary-Gonadal Interrelations—Nelson discusses cell counts on the anterior lobes from sixty-eight normal male and fifty-six female rats showing that the male gland has a higher percentage of basophils and acidophils and a lower percentage of chromiophobes than that of the female. The anterior pituitaries from twenty-five castrate male and seventeen spayed female rats that had been injected with estrogenic substance showed a profound decrease in the percentage of both castration cells and nonvacuolated basophils. Evidence indicates a fundamental difference in the sensitivity to the gonad hormone on the part of the male and female hypophysis, and that may explain the cyclic character of female reproduction and the absence of a cycle in the male. In the female the production of the estrogenic hormone attains periodically a concentration sufficient to suppress the production of the gonadotropic hormone. As the production of the estrogenic hormone decreases with the lack of stimulation, the gonadotropic hormone is secreted again and a new cycle is initiated. In the male the hypophysis is less easily influenced by gonad hormone with the result that apparently it is never suppressed to the extent that the male reproductive functions exhibit cyclic characteristics. The pituitary-gonadal interrelations also appear to be concerned in the control of certain other physiologic processes. In guinea-pigs—twenty-six males whose mammary glands had been caused to proliferate through the agency of ovarian grafts or estrogenic injections, eight parturient females and seventeen nonpregnant females—it was possible to promote or suppress lactation by varying the amounts of lactogenic hormone and estrogenic substance that were administered. Estrogenic substance also has been shown to be active in the control of experimental pancreatic diabetes. In four monkeys the profound hyperglycemia and glycosuria that followed pancreatectomy were abolished by the injection of estrogenic substance.

Differentiation of Strains of Hemolytic Streptococci

—Lancefield and Hare show by precipitin tests that the majority of strains from definite infections of the uterus are members of group A. The majority of hemolytic streptococci from the birth canal that do not bring about active infections are not members of this group. Most of them fall into either group B or group D, the former being identical with certain strains causing bovine mastitis, and the latter resembling *Streptococcus faecalis* more than *Streptococcus pyogenes*. These two groups have been confirmed serologically. The remaining noninfective strains fell into groups C, F or G or were unclassified. In their biochemical reactions they resemble group A. That they differ immunologically from group A strains can hardly be doubted. The differentiation, by a comparatively easy precipitin test, of hemolytic streptococci that are potentially infective from those which are harmless to man is entirely feasible. It seems highly probable that the human nasopharynx is the main reservoir of group A strains in nature. Because of this and because of the great rarity of group A hemolytic streptococci in the normal vagina before childbirth, there can be little doubt that the majority of puerperal hemolytic streptococcus infections are due to inoculation from some other source than the patient's genital tract and probably arise from the nasopharynx in the patient or attendants. Hemolytic streptococci may be harbored in the birth canal before or after delivery without causing disease, provided they belong to serologic groups other than group A. Group A hemolytic streptococci, on the contrary, are usually absent from the vagina before delivery or are exceedingly rare as the authors show by the failure to find organisms of this group in cultures taken before delivery from their series of patients. However, group A hemolytic streptococci, if present in the vagina before delivery, almost always give rise to serious puerperal infection. Accordingly, group A strains are probably

the only hemolytic streptococci capable of causing definite puerperal infection in the human species, and such infection almost invariably occurs if group A hemolytic streptococci are present in the vagina.

Neutralization Test in Poliomyelitis

—In experiments devised to compare the neutralizing action of normal adult human serums on different strains of poliomyelitis virus and to fill in certain gaps in their series of neutralization tests with different strains of virus on different types of cases in different age groups, Paul and Trask made the following observations.

- 1 The difference between two human and two passage strains of the virus when tested by the neutralization method amounted to about 25 per cent, and there was less power in normal adult serums to neutralize human than passage strains of virus.
- 2 The differences between the two human strains amounted to 15 per cent, and between the two passage strains to 8 per cent, the last figure falling within the limits of the experimental error of the method. The extent to which these observations affect certain concepts with regard to the epidemiology of poliomyelitis based on experiments on passage strain neutralization can not be determined from the data presented in this paper, except that they more or less confirm the view previously derived from passage strain experiments that from 70 to 95 per cent of normal urban adults possess in their blood a substance which neutralizes poliomyelitis virus in a given amount. However, certain other indications appear when the present results are supplemented by those that the authors obtained previously. Primarily, they found no relation between the clinical acquisition of poliomyelitis and the presence of substance in the serum which neutralizes a passage strain of poliomyelitis virus. With a passage strain the results seem rather to bear a closer relationship to age than to illness. With a human strain they obtained results in which there is some evidence, shown only in the juvenile group, that acquisition of the clinical disease is accompanied by the appearance of antiviral properties in the blood.

Studies on Hemolytic Streptococcus of Human Origin

—Ward and Lyons describe four common variants of the hemolytic streptococcus of human origin and designate them the F, M, attenuated M and C variants. The F and M variants have been isolated only from the blood stream in streptococcal infections. Only the M, however, has any primary virulence for the mouse. Both these variants resist phagocytosis in human blood under suitable conditions, and this appears to be a reliable test for human virulence. The attenuated M variant, found only in laboratory cultures, has a capsule as well developed as that of the virulent variants and yet does not resist phagocytosis. The C variant has no capsule and is readily phagocytized. It appears to correspond to the avirulent variant in other species. The authors are inclined to regard the F variant as the parent form of the *Streptococcus haemolyticus* of human origin since they have encountered it only in primary isolation. On the other hand, all the other variants may be derived from the F. While the F variant was isolated from the blood stream the

whole year round, the M variant was isolated in blood cultures only during the winter months—the so called streptococcus season. Since it is known that the M variant may be derived from the F by mouse passage, it is conceivable that the winter prevalence of the M variant may be due to the high incidence of infections of the upper respiratory tract and consequent frequent passage of the hemolytic streptococcus from one patient to another

Familial Renal Glycosuria.—Brown and Poleshuck present four cases as additional evidence of the familial or hereditary nature of the condition known as renal glycosuria. These observations help to substantiate the belief that it is an entirely benign condition. Two of the patients have been known to have glycosuria for seventeen and sixteen years, respectively. At its discovery the diagnosis of diabetes mellitus was made in each case and the treatment for that disease was instituted. The other two patients have absolutely normal dextrose tolerance tests. All these patients showed dextrose in all specimens of urine examined, in one patient even during the hour in which the blood sugar level range was from 85.8 to 50 mg per hundred cubic centimeters. In spite of the persistent loss of sugar in the urine there has been no loss of weight, or polyuria, in any of the four patients. In fact, one patient gained 21 pounds (9.5 Kg) in a period of six weeks on a high caloric diet as reported by Brown and Ralli, and this diet in

no way affected his carbohydrate tolerance. In addition, over a period of two years there has been no change in his carbohydrate tolerance as shown by dextrose tolerance curves

Amidopyrine and Granulopenia.—Limarzi and Murphy report a case of recurring granulopenia in which there were recoveries from four attacks. In all four there was granulopenia and in three a leukopenia. Analysis of the differential blood counts shows that the case was one of granulopenia and differentiates it from aleukemic lymphadenosis and aplastic anemia. Recovery from the first attack followed a blood transfusion that was associated with a severe immediate and delayed reaction. Recovery from the second and third attacks occurred spontaneously. Recovery from the fourth attack occurred after the administration of yellow bone marrow and liver extract (by mouth and parenterally). In the fourth attack large doses of amidopyrine (a total of 370 grains, or 24 Gm) were administered during the malignant phase and were continued into the recovery phase, showing that it was not possible to depress the granulocytosis by the administration of amidopyrine. Since recovery from the last attack, doses of 15 grains (1 Gm) of amidopyrine have been given without influencing the total or differential white count. The amidopyrine patch test was negative.

Effect of Morphine on Human Ureter.—Ockerblad and his associates studied the effect of morphine on the intact human ureter in twenty-four patients by means of hydrophographic tracings by Trattner's method, and some were subjected to roentgenoscopy. Morphine given subcutaneously in the usual clinical doses was found to increase markedly the ureteral tone and the amplitude of the contractions. The larger the dose the greater the effect. The effect is produced by morphine in from two to five minutes and persists for at least three hours and probably much longer. Atropine in doses of $\frac{1}{100}$ grain (0.00965 Gm.) invariably stops the contractions of the morphine stimulated ureter with a consequent loss of tone but does not act strikingly or constantly when given alone. The usual notion that morphine quiets the ureter is wrong and the view based on the experimental data which indicates that morphine stimulates the ureter is the correct one.

Endocrinologic Relationships of Prostatic Hypertrophy—Deming and his co workers in their approach to the study of relationships between the prostate and the endocrine glands studied the influence of castration on the genital tract of three monkeys and two controls. In the castrated animal the seminal vesicles as a whole are smaller and the diameter of the individual tubule is lessened. The prostate has lost in volume. Histologic sections show the expected decrease in height of prostatic epithelium and the size of the individual tubules. Despite the atrophy demonstrated the effect of castration is not so precipitate or complete as it is in the rat. The authors now believe that prostatic hypertrophy arises from the right and left lateral lobes of the prostate and the prespermatic lobe of the prostate and from the submucosal glands of the prostatic urethra and trigon. The anatomic origin of prostatic hypertrophy has an important bearing on the endocrine relationship. Hypertrophy of the submucosal glands arises from the prostatic urethra and should not be influenced by the pituitary-testicle-prostatic relationship. Experimental studies in the castrated monkey are compatible with this idea as castration failed to show any change in the mucosa of the prostatic urethra. Hypertrophy of the prostate has been the subject of an endless dispute as to whether it is a hyperplastic process or a true neoplasia. In all cases of so called hypertrophy there is an atrophy of the uninvolved portion of the gland. This may be ascribed to pressure although it has not been possible to prove this hypothesis. The endocrine relationship on this already atrophied true prostatic tissue following castration would be a negligible factor in relieving obstruction. The authors' work leads them to believe that the monkey does not have submucosal glands in the prostatic urethra but conversely, that the rat has all the anatomic origins necessary for prostatic hypertrophy.

High Voltage Treatment of Cancer—In treating cancer in any stage Smith divides the skin surrounding the tumor in as many 15 by 20 cm. areas as possible and directs the beam of radiation directly toward the tumor. He administers 300 roentgens daily to a single area and treats all areas in rotation until each has received a total of 2,100 roentgens. In the event of the tumor being located close to the surface, the tumor receives additional treatment of one-half erythema dose of low voltage through the use of 185 kilovolts of mechanical rectified current and filters of 0.5 mm of copper and 1 mm of aluminum at a skin distance of 50 cm. The low voltage treatment is administered immediately following the completion of high voltage series. When dealing with recurrent nodules following mastectomy, which frequently occur in and under the skin on the chest wall, the author proceeds in a similar manner employing high voltage radiation for its effect on the deep structures and modifying the voltage to produce a much longer wavelength for the skin effect. Usually 140 kilovolts of mechanical rectified current, 3 mm of aluminum filter, 28 cm focal skin distance is applied for a sufficient time to produce a threshold erythema. The combination of extremely highly filtered x-rays of a very short wavelength and the low voltage or longer and less penetrating radiation seems to produce more rapid recession of cancer tissue. This effect is not obtained when either is employed singly. The marked relief of symptoms and rapid recession of the tumor mass often permit surgical removal, which otherwise would have been impossible. The microscopic examination of numerous sections of tumors treated with high voltage radiation prior to removal shows many striking changes of the cells.

Preparation and Administration of Amniotic Fluid Concentrate—Johnson states that the action of amniotic fluid concentrate on the peritoneum is to stimulate the production of a defense exudate similar to that laid down in the presence of infection. It accomplishes an early peritoneal immunity, giving maximal protection with minimal physiologic disturbance. Its use is especially indicated in surgical procedures of the peritoneal cavity involving widespread trauma or contamination. Operative introduction may be practiced as a routine in all primarily clean cases of abdominal surgery. Preoperative instillation is usually reserved for cases reputed to have a high mortality from postoperative peritonitis. The dosage ranges from 50 to 300 cc, depending on the method of introduction, the nature and severity of the surgical procedure and the size of the abdomen. The dosage for preoperative instillation is from 50 to 100 cc from eight to twelve hours before operation. An intraperitoneal trocar or spinal needle (18 to 20 gage) may be used to accomplish preoperative instillation.

Forced Perivascular Drainage of Central Nervous System—Retan treated a case of syphilitic meningitis in 1930 in an infant, aged 6 months, which had a progressive hydrocephalus. Vigorous antisyphilitic treatment for three months failed to produce any clinical or serologic improvement. He then decided to alter the osmotic pressure of the blood stream by the intravenous injection of a hypotonic solution containing an arsenical, also to drain the spinal fluid, hoping that it might be possible to draw enough arsenic through the lesions of the central nervous system to produce a therapeutic effect. After four such treatments the patient had apparently recovered and has developed normally since. The author suggests forced perivascular drainage as a term that describes the essential factor involved in this treatment. A study of 115 forced perivascular drainage treatments shows the following results in regard to cellular behavior in the spinal fluid. 1 Patients without active infection of the central nervous system fail to show any cells in fractions of fluid examined during the intra-

venous injection of hypotonic solution. 2 Patients with syphilis of the central nervous system, of a duration of many years and who have had years of antisyphilitic treatment, also fail to show cell response. Similar results have been obtained in cases of chronic encephalitis of a duration of six and seven years. 3 In cases of septic meningitis there is a steady reduction in the number of cells found in fractions of the spinal fluid throughout the treatment. These cells continue to be practically 100 per cent polymorphonuclear leukocytes. 4 In cases of acute poliomyelitis, during continuous drainage and before the hypotonic solution is injected into the blood stream, there is a reduction in the number of cells found in fractions of the spinal fluid. However, the relation between the percentage of polymorphonuclear cells and lymphocytes in the spinal fluid is not greatly changed. If a hypotonic solution is then injected into the blood stream there is a prompt increase in the number of cells found in fractions of the fluid, with a shift to a preponderance of lymphocytes. 5 In cases of chorea, in which the cells in the spinal fluid are all lymphocytes, usually with a normal cell count, almost all later fractions contain lymphocytes, usually in increased numbers. However, certain fractions may contain no cells. These cases show in their later fractions a very small number of cells as compared to the later fractions in acute poliomyelitis. The author's technic is given.

Urinary Excretion of Silica—Bloomfield and his associates examined 123 anthracite coal workers, twenty of whom had been out of the industry for an average of seven years, for urinary silica by the method of King and Dolan. The amounts of silica found in the urine varied from 0.6 to 117 mg and averaged 25 mg per hundred cubic centimeters. Normal persons were found to be excreting only an average of 1 mg per hundred cubic centimeters. A close correlation was found between the silica dust exposure of these men for a specified number of years and the amount of urinary silica. A study of former anthracite coal workers showed that, even after a lapse of several years away from any silica dust exposure, an increased amount of silica is being excreted by them. This furnishes additional evidence of the etiology of the disease.

Cause of Death Due to Liver Autolysis—Mason and Nau carried out experiments on dogs and rabbits to determine whether the type of diet could in any way modify their previous results in explaining the cause of death when liver tissue is found free within the abdomen. They believe that their investigations furnish a satisfactory explanation for the cause of death. Sectioned liver tissue undergoing aseptic autolysis within the abdomen is accompanied by definite damage to the host. This is evidenced by changes in liver and kidney of the host and also by toxic symptoms manifested. All their previous experimental data were obtained from dogs. Therefore, when the first three rabbits of the present series survived the operation the authors were of the opinion that the survival was due to the type of diet selected by the rabbit. This conclusion also agreed with the observation of Salzmann. Continuing their experiments they concluded that all the surviving animals received implanted liver tissue sectioned from the periphery of the liver. Such tissue proved to be free of the anaerobic bacillus. They further observed that the implanted liver tissue sectioned from the central portion caused death and also gave a positive culture for the organism. It has been observed by others that this organism may be injected in large amounts into the peritoneal cavity without causing the death of the animal. The authors injected the organism intravenously and found that it affected the animals little, if at all. However, if shortly after such an injection the animals were killed and incubated, the tissues were subsequently found completely riddled by the organism, the liver being destroyed. The sequence of events that leads to the death of the animals appears to be as follows. The bacteria remain in a latent state until stimulated to activity by the asphyxiation of the liver tissue. The activity of the bacteria then accelerates the production of toxic products and these, in turn, cause death by producing a chemical reaction. The picture is not that which is usually considered a generalized peritonitis, but the bacteria confine their activity locally to the selected substrate. The damage to the tissues of the host shown in the microscopic sections, with and without the presence of bacteria, suggests that the process which produces death is not necessarily a difference in kind but rather a difference in degree, the action of the bacteria only accelerating the liberation of toxins from the liver tissue. Trusler and Reeves have demonstrated the fact that the organism does not produce exotoxins, and it has been shown that the organism may be cultured within the abdomen, substrates other than adult liver tissue being used without causing death.

Effect of Viosterol in Jaundice—McNealy and his associates studied the relationship between viosterol administration and blood calcium in 810 unselected cases in an effort to determine clinically whether viosterol would decrease the bleeding tendency of cases of jaundice or hepatic insufficiency. The patients were grouped broadly into 376 surgical and 434 medi-

cal patients. The average dose of viosterol was 30 drops (2 cc.) of 250 D three times a day. In cases presenting acholic stools, bile salts also were administered to ensure the absorption of vitamin D. In addition, calcium and dextrose were sometimes administered orally or intravenously. This administration was done in the control cases in about the same proportion as in the definitive group. There is no single method of predicting a bleeding tendency that is applicable to all types of hemorrhagic diatheses. In purpura the platelet count and in hemophilia the Howell method of coagulation time determination are the most reliable methods of predicting a bleeding tendency. The test that the authors found reliable in cases of hepatic deficiency was an application of the Duke method after a pressure of 40 mm of mercury was applied to the arm. In this test the Ivy bleeding time does not normally exceed 240 seconds. In the hemorrhagic diathesis the Ivy bleeding time practically always exceeds 240 seconds provided there is active or latent tendency to hemorrhage. Viosterol 250 D in doses of 30 drops three times a day supported by bile salts only in the presence of acholic stools almost always succeeded in reducing the prolonged Ivy bleeding time in cases of jaundice or hepatic deficiency to within normal limits in from four to seven days, provided the hepatic deficiency was not too far advanced or fulminating in its progress. With the reduction in the Ivy bleeding time, the hemorrhagic tendency would subside and the clinical condition improve. The most plausible hypothesis in explanation is that in hepatic insufficiency there is difficulty in absorbing fat soluble vitamins, and the deficiency in the latter aggravates the bleeding tendency. When an excess of fat soluble vitamin is exhibited in the form of viosterol this deficiency is corrected. In complete acholia, the absorption of viosterol is practically inhibited. The administration of bile salts then permits the absorption of viosterol.

Treatment for Fractures of Shaft of Femur—Griswold applied the following method of treating fractures of the shaft of the femur, five of which were ambulatory. Under spinal or local anesthesia the patient is placed on the fracture table and extension by Collin's hitches is applied until the length of the limb is restored. After the skin is prepared, a steel pin, one-eighth inch in diameter and from 6 to 8 inches long, is inserted transversely through the distal fragment just above the adductor tubercle. A second pin five thirty-seconds inch in diameter and from 8 to 10 inches long, is inserted in the anteroposterior direction at or slightly below the level of the lesser trochanter. Accurate placement is aided by the fluoroscope. These pins are inserted directly through the skin. The distal pin is slung from the suspension bar of the table by a suitable caliper and lifted to correct flexion of the distal fragment. Flexion of the proximal fragment is corrected by a clockwise motion of the upper pin, which is held manually in a caliper. From the anterior aspect the deformity is corrected by abduction or adduction of the distal fragment combined with medial or lateral traction on the proximal pin. Rotation is corrected by appropriate motion of one or both pins. The position is checked by fluoroscopy or roentgenograms in two planes and any necessary residual correction is carried out. A nonpadded walking spica is applied according to the method outlined by Boehler and Schnek. The anterior superior spines and sacrum are protected by thin padding, which is covered by a circular layer of flannelet extending from the xiphoid process to the symphysis. A previously prepared roll of padding is applied to the tuberosity of the ischium for counterpressure. The pad is about 8 inches long and has the thickness and firmness of a Thomas splint roll. The long ends of the bandage are pulled snugly upward over the flannelet so that the pad impinges firmly against the tuberosity. Circular plaster bandages are applied to the trunk and pelvis and molded about the crest and spines of the ilium. Anterior and posterior splints are applied to the skin from the Collin's hitch well up over the pelvic portion of the cast and covered with circular plaster bandages closely incorporating both pins. On the perineal side of the thigh, plaster is modeled over the ischial roll to form a shelflike structure, which holds the roll in place and transfers some of the pressure of weight bearing to the ischium. The junction of the thigh and pelvic portions of the cast is strengthened by additional splints and bandages. When this plaster

has set, the Collin's litch is removed and the cast is extended. An anterior plaster splint is applied as far as the base of the toes and a posterior one to a point one-half inch beyond the tips of the toes. These are covered with circular plaster bandages, making firm union with the rest of the cast. A Boehler walking iron is incorporated when the plaster has hardened. Trimming of the cast is carried out to uncover the upper part of the abdomen and allow free motion of the uninjured thigh. Weight bearing is allowed as soon as the plaster is sufficiently hard and roentgenograms have checked the position in the cast. Weight bearing should be painless after the first few days. The cast remains in place throughout the period of healing and may take the place of a convalescent walking splint. The pins may be removed at the end of about eight weeks. In feeble elderly patients too weak to carry the cast, the pelvic portion of the cast may be omitted or removed, leaving the ischial pad and maintaining firm fixation of the proximal pin, but pivoting of the proximal fragment on the pin might occur with resulting outward bowing. The omission of the pelvic cast is advisable only if the patient cannot walk and when it is essential to allow him to sit up in bed or a wheel chair.

Aseptic Uretero-Enterostomy—Poth describes an operative technic used in experiments on dogs for performing uretero-enterostomy that ensures complete surgical asepsis, healing in a clean anastomotic bed and assurance of an opening between the ureter and the intestine. The operation is divided into two stages. The first stage is concerned with embedding the intact and uninterrupted ureters in the wall of the intestine between the muscular layers and the submucosa. At the second stage the ureters are interrupted distally, openings are made between the ureters and the intestine, and the bladder is removed. Following the first stage, in which the two ureters are embedded simultaneously, the blood urea is usually increased for three or four days, corresponding to a temporary postoperative anuria. The animals drink and eat little during this time. They then begin to drink and urinate freely, and the blood urea returns to normal in the course of the next two days. Some of the animals eat, drink and urinate normally the day following operation, and the blood urea is not increased during this postoperative period. Intravenous urography reveals no dilatation of ureters or kidney pelves. At the second stage of the operation some three weeks later there is no evidence of hydro-ureters or hydronephrosis. The kidneys are macroscopically and microscopically normal. The establishment of the communication between the ureter and the intestine at the second operation is accomplished with a minimum of healing surfaces. The blood supply to the healing mucosal edges is unimpaired, and so fibrosis must be minimal. Urine flows freely into the proctoscope as soon as the opening is made between the ureter and the intestine. At no time has there been anuria during the second postoperative period. The urea content of the blood rises somewhat in the course of a few days and fluctuates from day to day, apparently depending on the amount of water and nitrogenous material reabsorbed from the intestine. Intravenous urography again reveals normal outlines of the kidney pelves and ureters.

Orbital Teratoma.—Kirwan presents a case of orbital teratoma in a girl baby which was brought to the hospital one week after birth. From the left orbital cavity a red mass about the size of an ordinary tomato protruded and in the middle of the mass the anterior half of the eye could be seen, the posterior half being buried in the growth. The cornea was irregularly opaque. The tension of the eyeball was normal. The size of the cornea appeared to be about the same as in the normal eye. The upper and lower eyelids were tremendously distended. The mass was growing principally on the inner side of the orbital cavity and was pressing on the lateral side of the nose, obliterating the left nasal cavity. The growth was hard and elastic. An exenteration of the orbit was carried out. The mass was incised and found to contain a cyst holding about half an ounce of serous-like fluid. The rest consisted of solid growth about the size of a large walnut. The baby had an uneventful recovery. The palpebral fissure and the eyelids are now (two years later) the same as in the right eye. There is only a small conjunctival sac. The vertical and the horizontal meridians of the bony orbit are somewhat larger than in the right eye. In other respects the child is normal. Serial sections show all the different types of tissues to be found in the body that originate in the three germinal layers: cartilage, nerve lymphoid tissue, fat, involuntary and heart muscle, skin, hair follicles, vascular tissue with melanoblasts, small intestine, liver and parathyroid. The eyeball and the optic nerve are normal and are independent of the origin of the tumor.

Outbreak of Gastro-Enteritis.—Fanning describes an outbreak of gastro-enteritis that differed from the ordinary type of outbreak of food poisoning in that it was spread over a period of a month and it was difficult to find any definite connecting link between the cases. The persistently negative bacteriologic observations in the pathologic specimens examined may be held almost certainly to exclude infection by the *Salmonella* or dysentery group of organisms. Attention is therefore directed to the part played by other organisms in gastro-enteritis. Although suspicion may fall on *Staphylococcus*

aureus as a possible cause of the outbreak there is not sufficient evidence to come to any definite conclusion. It would appear that *Staphylococcus aureus* is a potential cause of gastroenteritis and that butter, the only food that came under suspicion, is sometimes contaminated by that organism to a considerable degree. *Staphylococcus aureus* was isolated from the spleen in one of the fatal cases, but this is not necessarily significant. The symptoms consisted of severe epigastric pain, vomiting, diarrhea and collapse, with a normal or subnormal temperature.

Eosinophilia in Allergic Conditions—Knott and Pearson examined the sputum of 222 asthmatic patients for eosinophil concentration. They observed that there is a slightly increased tendency for respiratory infection to occur in asthmatic patients as age increases. Those developing asthma late in life are more likely to have an associated infection but the length of time during which they have suffered from asthma does not appear to be of importance in this respect. Cases in which there is a heavy infection give less evidence of protein sensitivity as demonstrated by skin reactions than the purely allergic cases and also show a smaller hereditary tendency, but the difference is not sufficiently marked to justify complete subdivision on etiologic grounds of this infected group from the purely allergic group. The difference clearly lies in the degree to which either the allergic or the infective factor predominates. The results of sputum examination, skin testing and analysis of the clinical history of these patients afford support for the suggestion that hypersensitivity is a factor in all cases of asthma. Many also show bronchiolar infection, sometimes so marked as to obscure the presence of eosinophils. Infection may be a dual factor in allergic patients. It may by actual damage to the bronchial mucous membrane and possibly by lowering the general health of the individual render him more liable to development of hypersensitivity, and in cases of subclinical allergy, when the tendency is present but symptoms have not occurred, the mucous membranes may be turgid and "boggy" and therefore more liable to be infected than healthy mucous membrane, when infection does occur, asthma is precipitated. An example of this mechanism is probably seen in the case of the infant with allergic eczema that clears up, leaving the baby well until perhaps 3 years of age, when an infection of the turgid mucous membrane occurs with subsequent development of asthma. Finally, notably various gram-negative bacilli so frequently found in sputum from asthmatic patients can, by their proteolytic action, actually produce histamine-like substances and these by direct effect on the bronchioles may act as a subsidiary cause of the asthmatic attacks. The evidence that the authors collected suggests that infection acts only as a subsidiary cause of asthma, which always develops on a basically allergic (hypersensitive) background.

Healing of Artificial Defects of Duodenal Mucosa—Florey and Harding demonstrate that cells typical of Brunner's glands regenerate conjointly with the cells forming villi, but owing to the fact that the muscularis mucosae does not reform they do not produce a layer of the same structure as Brunner's glands. Instead they are present where Lieberkühn's crypts would normally be. The regenerated Brunner's gland cells are apparently identical with those of true Brunner's glands, so that it is probable that they secrete their contained mucus, which thus forms a film on the villi. It would appear probable that the new Brunner's gland cells spring from the old ones bordering the denuded area. If Brunner's glands when injured can produce epithelium identical with that which occurs on the surface of the stomach as well as epithelium indistinguishable from pyloric glands, it strongly supports the view that in the cat at least Brunner's glands can be regarded as an extension of the pyloric glands into the duodenum. True goblet cells have been observed to occur interspersed among the Brunner gland type of mucous cell. The experiments described by the author have been done on healthy cats and in all cases the ulcer showed evidences of active or complete healing. It is possible to consider that in the healing of "naturally" produced human ulcers a similar regeneration does not occur. It is therefore of interest to find from human pathology evidence of mucosal scars incorporating regenerated "Brunner's glands" at the bases of the newly formed crypts.

The Pituitary Gland in Addison's Disease—Crooke and Russell describe the chromophobe, acidophil and basophil transitional, and ripe acidophil and basophil cells in the normal pituitary when stained by a modification of Mallory's acid fuchsin aniline-blue method. They examined the cellular composition of the gland with the same technic in twelve cases of Addison's disease and made a comparison with the normal. The Addison's disease was due either to tuberculosis or to

atrophy of the adrenals This 'destructive atrophy' has been contrasted with "simple atrophy" secondary to destruction of the anterior lobe of the pituitary In five of the twelve cases the whole pituitary gland was cut in serial sections and differential counts of the cells were made according to Rasmussen's method The counts confirmed the impression gained from inspection The chromophobe cells are increased in number, and a variable proportion of exceptionally large examples is present The acidophil cells are reduced, but seldom conspicuously Constant features are the extreme reduction of the basophil cells and the presence of a series of abnormal basophil transitional cells Evolution of the thymus and hyperactivity of the thyroid have been found in most cases but not in all The reduction in the number of basophil cells in the anterior lobe of the pituitary is considered to be a constant change and the most significant change in the other ductless glands following destruction of the adrenal cortex in Addison's disease The authors suggest that this reduction is the cause of the low blood pressure and possibly of the hypoglycemia in the disease

Encephalomyelitis Produced by Yellow Fever Virus

—Findlay and Stern state that the neurotropic yellow fever virus produced in susceptible animals (1) an inflammatory reaction in the central nervous system, (2) degenerative changes in the nerve cells and (3) acidophilic intranuclear inclusions The inflammatory reaction was characterized by infiltration with mononuclear cells and proliferation of the microglia Degenerative changes in the ganglionic cells were present in all stages, from slight swelling of the body of the cell to neuronophagia with complete disintegration of the cell Specific acidophilic intranuclear inclusions were seen only in ganglionic cells that had not undergone extensive degeneration and never in cells exhibiting neuronophagia The inclusions did not stain with the Feulgen technic Demyelination was not observed

Vascular Transportation of Carcinoma Without Local Metastasis—Oertel presents an instance of a quantitatively massive vascular transportation and generalization in a cancer of the stomach, which throughout maintained a purely intravascular restriction without transgression beyond it to the actual formation of secondary organic tumors At necropsy the case appeared to be free from such metastasis, and only subsequent microscopic examination revealed its concealed generalization From his observations the author believes that the extensive generalization is in all probability not so much an evidence of a massive, sudden invasion as a peculiar restricted manner of cancerous progress which confines itself to the blood and lymph channels The evidence of the case points to the fact that cancer cells are not necessarily destroyed in the circulating lymph or blood of their host but, on the contrary, may thrive in it It is only the markedly retarded or arrested blood and lymph streams which affect their nutrition and growth adversely, for under those conditions nutriment needed in abundance by these rapidly multiplying cells falls below their requirement or is completely shut off The author points out that "aggressive" and "malignant" properties of tumor cells may be simulated and possibly explained by purely nutritive modifications, which their presence imposes on a stationary differentiated tissue He did not observe evidence of a specific antitumor-cell body activity (Borst, Lumsden and others)

Treatment of Vulvovaginitis with Estrogenic Substance—Nabarro and Signy used estrogenic substance in the treatment of twenty cases of vulvovaginitis in children It was

necessary to douche these children once a day, and 4 Gm of iodine to one pint of water was the usual solution used The first ten patients were given intramuscular injections of estrogenic substance The dosage varied from 100 to 1,000 units daily and as a massive intramuscular dose from 20,000 to 50,000 units The second series of ten patients received the estrogenic substance orally In these the results were more uniform The first two received 1,000 units daily for an average period of ninety-three days The length of time between the start of the treatment and the last positive swab obtained was seventy-seven days in each case and both cases relapsed The next five patients received 2,000 units daily, the average length of treatment was fifty days, the time elapsing before the last positive swab was obtained was twenty-seven days, and four of the five children relapsed These seven cases were eventually cured as their relapses responded readily to further estrogenic treatment In the other three children the dose was increased to 4,000 units daily by mouth In these three children the average length of treatment was twenty-eight days, their last positive swabs were obtained only sixteen days after the start of the treatment and none relapsed In conclusion the authors advocate using from 1,000 to 2,000 units of estrogenic substance daily by injection or 4,000 units daily by mouth The latter, besides being a more congenial method to all concerned, can be given to outpatients and the results with the oral method seem more satisfactory, as none of the cases on this dosage have relapsed

Pituitary Disorders in Childhood—Gardiner-Hill points out that the clinical picture of pituitary disorders in childhood varies widely The hypopituitary conditions are in most instances well understood and their underlying pathology has been worked out Their symptoms vary to some extent according to whether or not a tumor is present The most characteristic feature of preadolescent hypopituitarism is a defect of growth Sex infantilism also occurs but is difficult to assess in young children and is, in fact, generally not recognized until the changes of puberty fail to appear Far less is known of preadolescent hyperpituitarism Moreover, adenomas of the anterior lobe, the characteristic effects of which have been so carefully studied in adults, are seldom found before the second or third decades, so that this line of approach to hyperpituitary pathology is not available in children A diagnosis of pituitary disorder in children appears to be made all too frequently and on insufficient grounds The terms hypopituitarism and Fröhlich's syndrome, for instance, are often used in reference to children who are grossly overweight, in the absence of growth and sex defects Fröhlich's syndrome in its true form is comparatively rare and the majority of fat children seen in medical practice have no defects of growth or sex development at all The reverse is more often the case Acceleration of growth during childhood and above the average stature are often found and judging by the family histories both the growth and obese tendencies are inherited characteristics Their growth characteristics suggest glandular overactivity rather than deficiency, and their metabolic tendencies an exaggerated storage mechanism rather than any fundamental inability to utilize food The

clinical syndrome of accelerated growth and obesity may possibly be due to hyperpituitarism. If so, it would seem to be a pituitary disorder in an inherited form. Genetic and chromosomal factors play an important part in the endocrine disposition. However, there is no certain guide to a diagnosis of endocrine diathesis and it would seem wiser to regard this particular syndrome as a constitutional peculiarity rather than an indication of definite pituitary disease.

Cultivation of Vaccinia—Taniguchi and his associates affirm the superiority of the egg method of Woodruff and his co-workers for preparing the bacteria-free variola vaccine. The authors have been able to prepare the bacteria-free vaccine that can affect the rabbit's skin in 1 in 10^{10} dilution by the method of Goodpasture, Woodruff and Buddingh for the cultivation of vaccinia in the chick membrane. They have also been able to produce ovovaccinia vaccine from their strain of varicella virus, which has a noticeable power to give rise to lesions. Thus, they are inclined to believe that a preventive method of chickenpox by inoculation can be devised. By the sequence of the application of the ovovaccine, diluted ten to twenty or again as much, to more than 100 vaccinated and unvaccinated persons, all the inoculations took with the normal process as with the vaccine lymph, but theirs, diluted one in ten, was observed to be more virulent. The authors also tested the ovovaccine of their varicella virus on human bodies and were convinced that vaccination with it is feasible in the human being. Of fifteen unvaccinated persons who had never been afflicted with the disease, two were unsusceptible. Four children who had the disease were unsusceptible. The inoculation of ten vaccinated children with varicella vaccine did not show an allergic reaction as in the case of variola vaccine. The lesion, however, is abortive and is not as typical as in unvaccinated children. The appearance of the local lesion of the varicella vaccine on the human body is practically the same as that of the vaccinia. With an incubation period of from forty-eight to seventy-two hours, papules were observed, which gradually advanced to vesicles and then to pustules with a halo around them. After about two weeks, the scabs fell off. The prophylactic inoculation against varicella with the testicular vaccine is also applicable besides the ovovaccinia vaccine.

- *Clinical Researches on Biliary Secretion E. Chabrol and M. Cachin—p 425
Debate on Diaphyseal Fractures J. Gosset—p 429

Research on Biliary Secretion—Chabrol and Cachin studied the biliary secretion in 300 patients by means of duodenal tube. Most of these showed a close parallelism between bile pigments, salts and cholesterol. Less frequently they observed a dissociation with relative increase of pigments and lowering of bile salts and cholesterol. More rarely a dissociation with increase in the bile salts was noted. The authors therefore conclude that duodenal tube cannot be relied on to establish the diagnosis of lithiasis and that cholesterol pigmentary dissociation is not characteristic of this condition. Duodenal tube shows, however, that all icterus tends toward dissociation with increase of the bilirubin at the expense of cholic acid and that the same dissociation exists in the cirrhoses with out icterus. Tube has similarly shown that the elimination of bile salts contrasting with relatively small amounts of bile pigments.

*Chronic Brucellosis in Man J. Jullien—p 451
Physiologic and Clinical Role of Bromine Exchange L. A. Jacobson—p 452

Chronic Brucellosis—Jullien describes two cases of chronic Brucella infection. In one case a cardiorenal condition and in the other a localized chronic rheumatism appeared undoubtedly to be of this origin. The author agrees that there is no doubt as to the existence of chronic undulant fever. He feels, however, that Brucella frequently prepares the field for associated infections, such as tuberculosis, syphilis, malaria and ordinary infective organisms. The latter should therefore be searched for. The best treatment is preventive. Symptomatic treatment must be applied and occasionally nonspecific vaccines appear to be of some value.

Intestinal Occlusion Due to Meckel's Diverticulum E. Guipponi—p 707
Intestinal Occlusion Due to Meckel's Diverticulum L. Tomasi—p 712

Histamine Test in Pulmonary Tuberculosis—Luzzatto Fegiz injects 1 cc. of a 1:1,000 solution of histamine subcutaneously in tuberculous patients. Following injection the skin is massaged vigorously and the patient remains in the recumbent position for several minutes until the signs of the histamine reaction appear. Auscultation is performed with quiet breathing and with forced breathing. The site of anticipated changes in the respiratory sounds and the appearance of moist rales are observed. Particular attention is paid to the anterior region of the thorax, in which many rales may be heard after injection, revealing foci previously silent. It is important that the patients do not cough much during the test, because coughing tends to decrease the rales rather than to increase them. The patient is examined three or four times in from two to three minutes and then rests for an hour until the signs of peripheral vasodilatation completely disappear. A raised pale wheal surrounded by an area of erythema appears locally at the point of injection after one minute. Immediately afterward peripheral vasodilatation is manifested in the face, the conjunctiva, the neck and the upper part of the thorax, reaching its maximum in five minutes. The patient frequently has a feeling of heat in the face, mild headache, palpitation of the heart and, less frequently, a feeling of constriction of the thorax and a dry cough. The changes in respiration several minutes after injection are (1) increased harshness of the respiratory sounds and (2) disappearance of cogwheel respiration. Rales appearing after injection of histamine in areas where there was previously no moisture are subcrepitant or inspiratory rales of medium size. In cases in

which there is ulceration the rales acquire a clear resonant sound. Frequently dry rales of bronchial quality occur, such as sibilant rales and rhonchi. All auscultatory signs disappear after from fifteen to twenty minutes. Of fifty cases presenting various pulmonary tuberculous lesions, eight showed localized cogwheel breathing following injection, thirteen showed rales, thirteen showed an increase of preexisting signs of moisture and modification of the quality of the rales, six showed rales and cogwheel breathing and ten showed no modifications at all. There were no contraindications, with the exception of patients presenting bronchial stenosis. The test was well tolerated in all instances.

*Depigmenting Action of Microsporon Furfur. F. Franchi — p. 321
Sepsis Due to Pseudomonas Pyocyanea with Benign Course. Case. R. Duroso — p. 326

Depigmenting Action of Microsporon Furfur—Franchi exposed several patients presenting tinea versicolor to ultraviolet irradiation. After irradiation the author treated the dermatosis with lemon and sodium thiosulphate. This has the double purpose of completely eliminating the mechanical protective factor represented by the parasite mixed with the desquamated skin and the other eventual pathologic changes caused by the disease. No appreciable inflammatory reaction was produced and total disappearance of the tinea lesions and of the parasites, checked by repeated microscopic examinations, occurred. The author exposed skin areas previously invaded by the parasite but normal in appearance, and healthy segments of skin, to slight irradiation because an intense erythema would have covered up everything. Twenty-four hours after irradiation, anemic spots with clear margins, representing the negative image of the dermatosis, are observed in the erythema. By their form and site they correspond to the preexisting small spots of tinea. In erythema a pigmentation takes place in which the already anemic small spots are recognized by a moderate achromia. These results demonstrate that *Microsporon furfur* in the skin is the cause of a depigmentation so mild as to escape observation and to require a contrast pigmentation of the surrounding skin to become visible. The removal of pigment in tinea versicolor results from (1) a mechanical protective action of the mycelia of the fungus and (2) the depigmenting action of the parasite itself. The author considers the marked depigmentation in tinea versicolor an exaggeration of a symptom normally observed in the ordinary forms of this disease.

Normal Image of Azygos Vein. F. C. Tucchi and J. E. Mosquera — p. 549

Intraspinal Bismuth Therapy—Bonorino Udaondo and his collaborators state that the treatment of dementia paralytica, taboparesis and tabes by intraspinal injections of a bismuth compound is practicable. It is possible during the course of the treatment, to reach high doses (0.12 Gm. per injection) of a preparation of carbonate of metallic bismuth but it is advisable to start the treatment with small doses (0.015 and 0.02 Gm. per injection) of the bismuth preparation and then to increase the doses until 0.12 Gm. per injection is reached. It is advisable to resort more frequently to the intraspinal bismuth treatment of the forms of neurosyphilis mentioned in order to establish a definite basis for indications, dosification and probable repetition of the treatment. The humoral changes observed in the patients both during the administration of the treatment, which consisted of seven or eight injections given at intervals of one or two weeks, and shortly after its discontinuation, were not related to the clinical improvement of the patients and do not authorize the authors, as yet, to draw definite or general conclusions as to their significance.

Langerhans Cells in Benign and Malignant Neoplasms. B. M. Klein and R. Missriegler — p. 280

Dermatomyositis and Poikiloderma with Changes in Muscles—Zoon points out that it is still a matter of dispute whether poikiloderma atrophicum vasculare (Jacobi) is a distinct disease entity or whether it is identical with dermatomyositis. He made comparative studies in two cases of typical dermatomyositis and one case of poikiloderma (Jacobi). A comparison of the histologic aspects of the skin disclosed that the following changes are present in both disorders: (1) a more or less severe atrophy of the epidermis, without great changes of the epidermal adnexa, (2) atrophy of the stratum papillare, (3) inflammatory manifestations, primarily of lymphocytic character, (4) changes in the elastic tissue, especially in the subepidermal and the perivascular region, (5) noticeable changes in the walls of capillaries and smallest arteries, and (6) pigment in the cutis. Essential differences could not be observed. The fact that in dermatomyositis the muscles are so noticeably involved constitutes, in the author's opinion, the only reason for the differentiation of the two disorders. However, Jacobi's original description of poikiloderma atrophicum vasculare mentions also great muscular weakness. Moreover, Oppenheim, in describing poikiloderma atrophicum vasculare, differentiates cases with and without muscular changes and Petges suggested the term poikilodermatomyositis. The author examined an excision from the quadriceps femoris muscle of the patient with typical poikiloderma and found the identical changes, although in a somewhat milder degree, that are observable in dermatomyositis. He concludes from this that in this case of poikiloderma the muscles were involved, although the clinical aspects did not indicate it. He advises the examination of the muscles in other cases of poikiloderma and thinks that thus it might be possible to establish the identity of the two disorders.

Dermatomyositis—Bezecky describes two cases of dermatomyositis. In one of the patients the disorder disappeared shortly after the extirpation of an ovarian carcinoma, and the author assumes a relationship between the intervention and the cure of the dermatomyositis. The second patient died, but in this one both breasts had carcinoma. On the basis of these observations the author considers it possible that in these two cases the symptoms of dermatomyositis may have been caused by toxins of the malignant tumors, perhaps by way of the sympathetic nervous system. He does not exclude the possibility that the cure in the first case may have been effected by the change in the internal secretion, which was produced by extirpation of the ovarian tumor. He believes that dermatomyositis is a syndrome that may be caused by various disorders.

Natural Diet and Protein Metabolism. A. Bickel — p. 533

*Treatment of Complicated Cases of So-Called Cardiospasm. H. Starck. — p. 537

*Lobar Pneumonia as Epidemic Disease. M. Gundel and E. Wallbrunn. — p. 539

Treatment of Cardiospasm—Starck discusses the non-surgical treatment (cardiotonic dilation) of cardiospasm. In the complicated cases the course of the esophagus is usually abnormal, for, as the disorder continues, the esophagus loses its normal form and becomes wider and longer. Whereas the portion between the cricoid cartilage and the hiatus in the diaphragm ordinarily measures from 28 to 30 cm., it may reach a length of 40 cm. in cardiospasm. The result is that the esophagus is no longer straight but takes a convex or a serpentine course. Occasionally the esophagus descends diverticula-like over the dome of the diaphragm. The older dilation instruments with their rigid guides are unsuitable for such complicated cases. In order to lead the instrument to the diaphragm-

matic hiatus, the author used mercury tubes (from 10 to 25 cm in length) as guides as a result of their weight they follow the shortest route downward, and because of their flexibility they follow the course of the esophagus. In some instances, somewhat more rigid guides have to be used, and, in cases with severe diverticulation, pieces of elastic catheters with diverticular guides are attached to the instrument, or hard rubber guides, bent in the manner of a diverticular catheter are used. With the aid of this instrumentarium it was always possible to pass the hiatus and bring the dilator to the right location. The difficult cases should be treated before the x-ray screen. Force should be avoided. Once the guide has passed the hiatus, the rigid dilator follows easily. The dilation is done suddenly and under strong pressure, so that the ring of the cardia is opened in from one to two seconds, and almost before the patient realizes it the instrument is removed again. The author considers complicated cases of cardiospasm those that occur in children. He suggests a method for these cases. Other difficult cases are those in which the neck is extremely short or in which the head cannot be bent backward. He emphasizes that in complicated cases the treatment requires considerable experience and practice.

Lobar Pneumonia as Epidemic Disease—Gundel and Wallbruch describe an epidemic of lobar pneumonia in a village of approximately 300 inhabitants. Two weeks before the appearance of the first case there had been a mild influenza epidemic, but the nineteen cases of lobar pneumonia that developed subsequently were readily differentiable from the influenza. The nineteen cases occurred in twelve out of the total number of fifty families. The epidemic commenced among the school children. In seventeen cases pneumococci of type I were isolated and in one case the examination of the sputum gave negative results but serologic tests revealed the presence of specific antibodies against pneumococci of type I. The type diagnosis failed in only one of the cases. Examination of the sputums or of the pharyngeal smear preparations disclosed a high percentage of carriers of pneumococci of type I among the inhabitants of the village. The authors conclude that the epidemic appearance of lobar pneumonia cannot be doubted and that it may be grouped with the true infectious diseases.

Klinische Wochenschrift, Berlin

- *Progressive Lipogranulomatosis of Musculature Pathogenesis of Progressive Osteoplastic Myopathy Teutschlaender—p 451
- New Studies on Presence of Acetylcholine in Blood R Ammon—p 453
- *Enteral and Parenteral Administration of Calcium Hoesch—p 461
- *Granulocytopenia Following Medication with Amidopyrine B von Bonsdorff—p 465

Progressive Lipogranulomatosis of Musculature—Teutschlaender reports the formation of lipogranuloma in the musculature of a child, who has been under his observation for five years. He shows that this disorder, which formerly was regarded as probably an early stage of myositis ossificans progressiva, is really not a disease of the muscular parenchyma but a disorder of the intramuscular connective tissue or, rather, of the lipomatous internal perimysium. In lipomyomatosis that develops on the basis of a congenital (or hereditary?) constitutional anomaly there appear, as the result of a locally progressing endarteritis obliterans and of progressive trophic disturbances, necroses with reactive granuloma formation into which calcium salts are deposited. The author applies to these formations the term lipocalcinogranulomatosis. In the reported case the lipocalcinogranulomatosis was symmetrical and progressive. Some processes underwent inflammatory softening, fistula formation, evacuation of the fat-calcium emulsion and finally healing and cicatrization, while others, apparently by metaplastic bone formation, developed into progressive osteoplastic myopathy. The author insists that the disorder, the nature of which has been misunderstood heretofore, is a well defined disease entity and should be differentiated from its possible after-disease, "progressive osteoplastic myopathy," for it does not necessarily terminate in ossification. It may be assumed that, as in other disturbances of the muscular and motor apparatus, this disorder occurs also in different types. The reported case might be considered as an example of an

infantile or juvenile scapular or scapulohumoral type of lipocalcinogranulomatosis.

Administration of Calcium—Hoesch stresses the therapeutic value of calcium gluconate in tetanic spasms and reports his studies on the action of enteral and parenteral calcium therapy on the calcium content of the serum. Whereas former studies investigated the changes in the calcium content only for a relatively short time after the injection, he studied the changes, at intervals of two or three hours, for a period of one or two days. He points out that there are three fractions of calcium in the serum: (1) the ionized calcium, (2) the calcium in a complex compound and (3) the colloidal calcium. In the first series of his experiments he determined the total calcium content and the ultrafiltrable calcium. The total calcium minus the ultrafiltrable calcium equals the colloidal calcium, for the ultrafiltrable calcium contains the ionized calcium as well as the calcium in the complex compound. The colloidal calcium is the fraction that is combined with the protein. The author's studies disclosed that the intravenous injection of calcium gluconate increases the ultrafiltrable calcium greatly and the colloidal calcium slightly. The two fractions reach their maximum usually at different times. Two forms of hypocalcemia occur after parenteral and oral calcium therapy. The intravenous administration of calcium is followed by a renewed increase in the blood calcium after fourteen or sixteen hours. The hypocalcemia following the intravenous administration of calcium gluconate is occasionally accompanied by mild tetanic symptoms. Repeated medication with calcium (oral or parenteral) at shorter or longer intervals (up to twenty-four hours) produces an effect on the course of the calcium content of the blood similar to that produced by the repeated administration of carbohydrates on the blood sugar of persons without diabetes, that is it prepares the way for the assimilation. The author thinks that this facilitation of assimilation is effected by intermediary factors.

Granulocytopenia Following Medication with Amidopyrine—Von Bonsdorff reports the history of three patients with granulocytopenia. In two cases it was virtually certain that medication with amidopyrine was the cause and it was probable in the third case. In some persons a few small doses of amidopyrine elicit a granulocytopenia, while in other cases it appears suddenly some time after large doses of the substance have been administered without causing disturbances at the time of administration. This shows that therapeutic doses of amidopyrine in sensitive persons may have a detrimental effect on the general condition and on the hematopoietic organs. The action on the granulocytopoietic apparatus is stimulating as well as inhibiting. The total number of granulocytes decreases, but the immature and young forms increase. In some instances, leukocytosis may follow. Amidopyrine influences the organs that produce the monocytes and lymphocytes as well as the erythropoiesis. The changes disappear spontaneously when medication is discontinued. However, it may be assumed that the continuous use of amidopyrine may eventually cause grave clinical symptoms. Animal experiments proved likewise that the administration of amidopyrine or of related substances may eventually impair the hematopoietic organs and lead to leukocytosis, leukopenia or anemia. Moreover, amidopyrine tolerance tests on persons who have had granulocytopenia indicate that amidopyrine may lead to granulocytopenia.

Medizinische Klinik, Berlin

- Periodicity of Genital Hemorrhages. H Knaus—p 371
- *Chemotherapy and Serotherapy of Spirochetal Jaundice (Weil's Disease) P Uhlenhuth and E Zimmermann—p 375
- *Antianemic Substances in Urine A Decastello—p 377
- Therapeutic Action of Intravenously Administered Liver Extracts in Hypochloremic Anemia R Bauer—p 380

Chemotherapy and Serotherapy of Spirochetal Jaundice—Uhlenhuth and Zimmermann studied the therapeutic action of several bismuth preparations in guinea-pigs that had been infected with spirochetal jaundice. They found three preparations quite effective and think that with due caution these preparations could be tried in human subjects with spirochetal jaundice. These preparations should be administered

intramuscularly or intravenously. Although chemotherapy of spirochetal jaundice is still in the experimental stage, serotherapy has been proved effective. Studies on patients convalescing from infectious jaundice disclosed that the convalescent serum has the greatest therapeutic value when it is withdrawn between the thirtieth and the fiftieth day following the onset of the disorder. This convalescent serum should not be more than six months old at the time of administration. Rabbit serums have about the same therapeutic value as human convalescent serums and they have the added advantage that they can be preserved for longer periods.

Antianemic Substances in Urine—Decastello gave patients with pernicious anemia daily enemas (300 cc.) of the urine of healthy persons and observed that as the result of this treatment the reticulocytes increased and subsequently the blood picture and the general condition improved. The same effect could be produced also with the urine of patients with pernicious anemia. The author tried the treatment with urine also on patients with other forms of anemia but it proved ineffective. He thinks that the antianemic substance in the urine is probably identical or related to Castle's intrinsic factor. This would indicate that this factor is not entirely absent in patients with pernicious anemia but that it may be present in the blood without reaching the stomach. In megalocytic-hyperchromic anemias with normal gastric chemistry (anemia caused by intestinal worms, anemia developing during pregnancy and some cases of pernicious anemia) the primary deficiency of the blood in antianemic substance may be the etiologic factor. The author thinks that the antianemic factor may eventually be chemically extracted from urine, and thus another biologic preparation would be available for the treatment of pernicious anemia.

Heredity of Deformities—Goldmeier studied twenty-two cases of congenital deformities such as clubfoot, harelip, cleft palate and micromelia. He was able to demonstrate hereditary transmission in nine cases. He found that the hereditary transmission is not necessarily strictly specific in that exactly the same disorder is transmitted, but that the defect may appear in a different form or that other defects may complicate the specific one.

Etiology of Eclampsia—Dienst, on the basis of his studies and of other reports reaches the following conclusion. The relative cardiac insufficiency during eclampsia which leads to an insufficient blood perfusion of the organs that form antithrombin (particularly liver, placenta and thyroid) and the consequent antithrombin deficiency of the circulating blood is, in the last analysis, responsible for the flooding of the arterial blood with the antagonists of the antithrombin, namely, with thrombin or thrombokinase. The presence of the large amount of thrombin has a toxic effect on all parenchymatous organs, the brain, the sympathetic nervous system and the entire capillary system. Among other changes it causes an albuminous degeneration of the fibers of the cardiac muscles, angiospasm, increased blood pressure and permeability of the capillaries, which explains the internal edemas. Serous transudation from the choroid plexus into the third ventricle leads to irritation of the center of convulsion and thus produces tonic-clonic spasms, that is the eclamptic convulsions. If the eclampsia takes a chronic course, the pulmonary circulation becomes involved and then the heart and the arterial circulation including the placenta. This also explains the development of hemorrhagic necroses in the myocardium, liver, kidney and placenta. The author considers the increase of thrombin the true toxin in eclampsia. The excess of thrombin causes general vascular spasms, oxygen deficiency and internal suffocation.

*Experiences with Auto-Urotherapy M Krebs—p 342

Clinical Aspects of Alveolar Enanthem in Measles H Seckel—p 351

*Abortive Form of Pneumococcic Peritonitis E Kramar—p 370

Experiences with Auto-Urotherapy—Krebs points out that if auto-urotherapy is employed in allergic conditions, the result may be favorable or a complete failure. This uncertainty makes it desirable to devise a method for the examination of the urine that will permit the determination of the probable efficacy of the urine in advance. The author's first aim was to detect differences in the urines that were highly effective or entirely ineffective in the same disorder. He found that the therapeutically active and inactive urines differed in a deviation of the normal ratio of oxydase and reductase. He determined the oxydases by means of the artificial oxydase system of Loele and the reductase according to his own method and he gained the impression that to a certain extent these methods permit the determination of the possible effect of the urine before its application. He found auto-urotherapy effective in Quincke's edema, laryngospasm, urticarial disturbances and some cases of migraine. The duration of whooping cough could be reduced in most cases (fourteen of eighteen) by means of auto-urotherapy. Some of the case reports indicate that the author injected 0.5 or 1 cc of urine. He cites another report indicating that in doses up to 2 cc urine may be injected many times. He emphasizes the necessity of sterility and the freedom from toxin. If a patient is sensitive to phenol, it is advisable to add another disinfectant to the urine.

Abortive Form of Pneumococcic Peritonitis—Kramar shows that pneumococcic peritonitis may occasionally take an abortive course. In the two cases observed carefully from the beginning, the disorder began with fever, vomiting and abdominal pains and resembled a simple gastric disturbance. The signs of peritoneal irritation did not develop until several hours later, were not accompanied by severe general disturbances, and disappeared again on the following day. The diagnosis was corroborated by abdominal puncture. The author thinks that the abortive form of pneumococcic peritonitis is not as rare as may be believed and that some cases do not come under medical observation or come so late that they are not recognized. He calls attention to the cases of lobar pneumonia in which operation is performed because appendicitis is suspected. Early operation is inadvisable in cases of pneumococcic peritonitis, because an abortive course is possible. Abdominal puncture and the bacteriologic examination of the punctate is helpful in establishing a correct diagnosis. The author thinks that a high degree of immunity against pneumococci is the chief cause of the abortive course. The term abortive pneumococcic peritonitis should be restricted to mild cases of short duration.

*Experimental Studies on Pathogenesis of Tuberculous Infection and Development of Primary Complex B Busson—p 385

Respiratory Therapy and Physical Exercise K Schutz—p 392

Studies on Pathogenesis of Tuberculosis—Busson observed a paralysis of the hind legs in one of a group of guinea-pigs that had been given a subcutaneous injection of a tubercle bacillus culture into the inguinal fold. The necropsy disclosed no signs of tuberculous infection, even at the site of injection. With the exception of hyperemia of the leptomeninges, there was nothing abnormal. Emulsions were prepared from the brain and spinal cord and were injected into guinea-pigs intracerebrally, intramuscularly or subcutaneously. The guinea-pigs that had been given the intracerebral injections developed, after ten or twelve days, severe cerebral symptoms, then paralytic disturbances of the extremities and finally tonic-clonic spasms. The disease usually lasted about five days. The necropsy of these animals gave essentially the same results as that of the first animal. The histologic examination of the leptomeninges disclosed infiltration, and the bacteriologic examination revealed the presence of tubercle bacilli in the leptomeninges. On the

basis of these observations and of reports in the literature the author concludes that a tuberculosis of the central nervous system is possible in which the changes that generally characterize tuberculosis are absent and in which the histologic aspects frequently can be correctly interpreted only on the basis of bacteriologic examination. Following further discussions on the absence of the primary focus in some cases of tuberculous infection, the author advances the theory of a regulatory action of the macro-organism on the course of the tuberculous infection and thinks that this regulatory action has failed in cases in which no primary focus develops and in which the central nervous system becomes involved at once.

*Aschheim-Zondek's Pregnancy Reaction and Roentgen Rays L. Nürnbergberger—p. 722

*Embolic Transmission of Foreign Body (Rubber Catheter) into Heart in Criminal Abortion J. Bláha—p. 746

*Use of Vernix Caseosa in Formation of Artificial Vagina and Histologic Examination of the Latter R. Kleitsman and L. Poska-Teiss—p. 755

Aschheim-Zondek's Reaction and Roentgen Rays—Nürnbergberger investigated the outcome of the pregnancy reaction in infantile female white mice that had been exposed to roentgen irradiation. The data given in a tabular report indicate that it is possible to elicit the Aschheim-Zondek reaction in infantile female mice even after prolonged irradiation with large doses of roentgen rays. This is surprising, particularly when it is considered that degenerative changes appear in the follicular epithelia a few hours after irradiation with large doses of roentgen rays. In order to gain a better insight into the processes that take place in the ovaries of the irradiated animals, the author subjected to histologic examination the ovaries of control animals that were irradiated and killed after the same number of days as those that had been given injections of pregnancy urine. In all ovaries, changes were evident that are known to be the result of irradiation, namely, shrinking of the ova, globular chromatin degeneration and vesiculovacuolar disintegration of the protoplasm of the follicular epithelia and shedding of debris of nuclei and of protoplasm into the follicular cavity. In spite of these considerable changes in the irradiated ovaries, the administration of the gonadotropic hormone was followed by maturation of the follicle and by formation of corpora lutea. The uterus of the animals treated with pregnancy urine was enlarged and thickened and in the vagina the typical cast-off, non-nucleated horny lamellae were found.

Embolic Transmission of Catheter into Heart Following Abortion—Bláha reports the history of a woman who requested a medical examination because on the previous day she had attempted an abortion by means of a rubber catheter. Examination disclosed a perforation of the cervix. Roentgenoscopy did not reveal the shadow of a foreign body. An exploratory laparotomy was resorted to, but a catheter could not be found. Curettage disclosed that there had been an incomplete abortion and it was assumed that the catheter had induced the abortion and had been expelled without the woman noticing it. Sepsis developed and the woman died on the seventh day. At necropsy, on examination of the cervical organs, the lower, rough end (evidently broken off) of the catheter, which was 23.5 cm long and 4 mm thick, was detected in the inferior vena cava near the diaphragm. From there the catheter extended through the right auricle, the superior vena cava and the innominate vein into the left common jugular vein, in which the upper, smooth end of the catheter was found several centimeters above the clavicle. A comparison of the conditions found at necropsy with the clinical course indicates that, following perforation of the cervix, the catheter must have entered a wide vein of the uterine plexus, from which it slipped directly into the right hypogastric vein and into the inferior vena cava. It may be deduced from a number of symptoms that the catheter reached the heart on the fifth day following its introduction into the uterus. At any rate the catheter must have been in the heart for about forty-eight hours without causing severe impairment of the heart action. The author reviews the literature on foreign bodies in the heart and found that in the majority of cases the foreign body was a projectile. He thinks that the reported case is the first one in which such a large

foreign body entered the heart by embolic transmission. He reviews cases from the literature in which catheters disappeared following introduction into the uterus. In some cases the catheter was extracted from the uterus, in others it entered the retroperitoneal tissue and was later extracted from an abscess, in others it entered the preperitoneal tissue and caused an abscess in the anterior abdominal wall, in others it entered Douglas's pouch, and in a considerable number of cases it entered the free abdominal cavity and produced diffuse peritonitis. The author stresses the necessity of careful inspection.

Vernix Caseosa in Formation of Artificial Vagina—The report of Bregård on wound treatment with vernix caseosa induced Kleitsman and Poska-Teiss to use vernix caseosa in the treatment of refractory bed sores. They gained the impression that vernix caseosa produced more rapid healing than did other measures, and they decided to use sterile vernix caseosa instead of epidermic flaps to cover the wound canal in the artificial formation of a vagina. They describe a case in which this was done and in which complete epithelization of the artificial vagina was obtained in a relatively short period. Histologic examination disclosed that the epithelium of the newly developed vaginal mucous membrane apparently did not develop from the elements of the vernix caseosa. The mode of action of the vernix caseosa is still a matter of conjecture.

Effect of Diphtheritic and Scarlet Fever Toxins on Heart—Reyngold studied the effects of diphtheria and scarlet fever toxins on the heart of a dog under the conditions of the Starling preparation of heart and lungs. The animal's own blood and Ringer-Locke solution were used for perfusion. Nine successful experiments were carried out. He found that the dog's heart is capable of tolerating large doses of scarlet fever and diphtheria toxins. The diphtheria toxin affects primarily the heart muscle, causing a diminution in the minute volume, lowering of pressure in the right auricle and acceleration of the pulse after an initial slowing. The diphtheria toxin is capable of producing at times a temporary initial stimulation of cardiac activity, causing an increase in the minute volume output of blood and an increase in the pressure within the right auricle. The scarlet fever toxin affects the heart musculature to a lesser degree than the diphtheria toxin. Its effects in the beginning are to increase the cardiac contractions with a consequent increase in the minute volume output and a fall of the blood pressure of the right auricle. This is followed by cardiac depression and involvement of the cardiac musculature as a result of which the minute volume output diminishes, the pressure in the right auricle increases and the pulse becomes accelerated. Scarlet fever toxin was found to lower the oxidizing power of blood in experiments. The alterations produced in the heart by the diphtheria or scarlet fever toxins are permanent and are influenced for only a short time or not at all by stimulation with cardiac stimulants and nutritive fluid (blood).

FOODS THAT COMMONLY DISAGREE WITH PEOPLE

WALTER C. ALVAREZ, M.D.
AND

H. CORWIN HINSHAW, M.D.
Fellow in Medicine the Mayo Foundation
ROCHESTER, MINN.

Which are the foods difficult of digestion or likely to cause distress of one kind or another? Which are the most likely to cause gas, abdominal discomfort, heartburn, regurgitation, "biliousness" or urticaria? Surely, after thousands of years of cumulative experience we physicians should be well prepared to answer these questions which are being put to us several times a day, and yet, it does not look as if we were.

Today the average physician when asked for advice as to diet, is likely to warn against the eating of fried or greasy or rich foods, or of foods that he himself cannot digest, or he will give a printed list, which may fit the needs of his patient about as well as the key to one door fits the lock of another. And if the patient should protest that he is unable to partake of, let us say, milk or eggs, he is likely to be told impatiently that the trouble is in his head and that he must do what he is told. Even the hospital dietitian is likely to insist that milk and eggs are invaluable "health foods" which must be taken every day if disaster is to be avoided and unless she is an unusually intelligent woman given to habits of independent thought, or unless she has worked with an allergist, she will not budge an inch from the way in which she was taught to go.

And who can blame her for this when her whole training was built around one idea namely, that of supplying to her patients, each day a diet complete enough to insure good growth in a baby rat? In recent decades the leaders in dietetics have been so absorbed in the search for "the little things in the diet" that there has been no time left for consideration of such a minor (?) matter as the digestibility of the foods that happen to carry the desired vitamins or iron or calcium. By digestibility we mean here the likelihood or unlikelihood that the food will disagree in some way with the person who eats it. Some of the books on diet fail even to mention digestibility, others comment briefly on the subject, and one book written by a practicing physician, has a short chapter on it.

DIFFICULTY OF DISCOVERING OFFENDING FOODS

Another reason for present-day disregard of this item of digestibility in a diet is doubtless to be found in the fact that the attainment of knowledge in this field is difficult. The most intelligent observer can easily be deceived and the patient may well be mis-

taken when he states his inability to eat some particular food. Often it was condemned unjustly and on insufficient evidence perhaps the fish was blamed when really the culprit was the tartar sauce, the cottonseed oil in which the fish was fried, or the pie that was eaten for dessert. Or the food eaten at dinner was blamed when really the offending substance was taken into the body with luncheon or breakfast. Or the upset was due simply to overeating or to back pressure from an over-filled colon, to annoyance over an argument at the dinner table, to an oncoming cold, or even to a slight flareup in an unrecognized cholecystitis. Under the circumstances, surely, no one should reject a food unless it gives trouble repeatedly and at times when other causes for the symptoms can be excluded.

THE ATTITUDE OF THE PHYSICIAN

There appear now to be three courses open to a physician: one, to pooh-pooh all but the severest manifestations of food sensitiveness, another, to look on almost every illness known to man as due to food allergy, and another, to steer his way carefully between the error of operating on a patient with an allergic intestinal crisis and the tragedy of trying to cure with diet a patient with empyema of the gallbladder.

There is no doubt that some half-starved "dyspeptics" dominated by the fear of many foods, can be cured only when as an experiment, their protests are overridden and they are made to eat, but it is equally certain that others, now badly handicapped, could easily be cured by the complete removal from their diet of one or more foods.

THE CONTRIBUTION OF THE ALLERGISTS

Curiously, in the advance that is now being made it is not the gastro-enterologist or the dietitian who is leading the way but the allergist. He became interested in diet through his efforts to help persons with asthma, hay fever and skin lesions. First he tried to discover the offending foods with the help of skin tests, but when these often failed him he turned to the method of trial and error first simplifying the problem by limiting the patient to a few foods, and these chosen from a list of the ones that seldom give trouble.

FOOD SENSITIVENESS NOT ALL ALLERGIC IN NATURE

Perhaps because this new knowledge has come from the allergists it is customary now, when a food disagrees with a patient to take it for granted that the offending substance was a protein and the mechanism of injury an allergic one. Actually, there is no reason for assuming that even a large number of the patients with whom foods disagree suffer in an allergic way. The trouble does not have to have an allergic mechanism back of it, even when it occurs in persons who suffer with allergic types of disease. Thus one can hardly

call sulphur dioxide a protein, and yet the inhalation of this substance may throw an asthmatic person into an attack. Similarly, substances such as pepper and mustard and alcohol may well alter peristalsis by direct irritation of nerve endings in the mucosa of the stomach and the intestine. There are reasons for suspecting that cucumbers, melons and tomatoes contain an emetic substance that in small doses produces only regurgitation and belching. Fats can produce distress simply because of their tendency to delay the emptying of the stomach, and flatulence and colicky distress can be due to the presence in some foods of laxative substances which in small doses produce only peristaltic unrest.

Furthermore, the stories that many persons tell are incompatible with the theory that their sensitiveness is allergic in nature. For instance a woman who usually vomits milk states that she can digest it perfectly when a patented egg-powder is added to it, and two others who regurgitate or vomit cold milk have no trouble when this food is warmed. Many others who say that they are highly sensitive to undisguised egg will eat angel food cake, custard and chicken and the many who have trouble with boiled cabbage can usually digest cole slaw.

If as we believe, much of the trouble caused by food is due purely to irritation of the intestinal mucous membrane by chemicals or by woody cellulose it is easy to see why in so many cases the skin tests are useless. One can expect them to be positive only when the symptoms are due to unchanged protein getting into the blood stream.

It is the severe reaction at a distance from the abdomen that is most likely to be due to foreign protein but even some of these upsets can be due to small amounts of poisonous drugs, such as the oxalic acid in beet greens, the solanin in potatoes, the powerful hemolysin in raw onions¹ or the laxative substances in rhubarb and prunes.

FOODS THAT COMMONLY DISAGREE WITH THE EATER

But to get back to our original problem how can we physicians secure information as to the foods that commonly disagree with the eater? Probably the best way would be to list all the foods incriminated in the production of symptoms in hundreds of cases of fairly definite food sensitiveness. Thus Rowe² reported the curing of 175 patients by the elimination from the diet, in order of frequency, of wheat, eggs, milk, chocolate, cabbage, tomato, oranges, walnuts, strawberries, bananas, white potato, cauliflower, oats, pork, carrots, rice, oysters, salmon, celery, lettuce, squash, apricots, apple, cantaloup, grapefruit and peaches.

Rowe's list of skin reactions to food observed in 500 patients is also of interest but probably not so helpful. Most commonly irritating to the skin were wheat, spinach, egg, milk, celery, squash, string beans, corn, cabbage, tomatoes, cauliflower, white potatoes, black pepper, onions, rice, oranges, asparagus, turnips, grapefruit and lettuce.

Vaughan's³ list is not comparable with Rowe's, because he studied 508 persons living in villages in Virginia and then chose from these the 244 who complained only of symptoms designated by him as being

those of "minor allergy." These are nausea, vomiting, heartburn, belching, flatulence, cramps, hives or rashes, headache and the prolonged tasting of food. The foods blamed were, in order of frequency, cabbage, onion, tomatoes, cucumbers, strawberry, watermelon, pork, cantaloup, apple, beans, potato, sea foods, banana and egg.

Obviously, further research is needed, and particularly with large unselected groups of persons. Fortunately there is enough agreement among investigators so that one can now be fairly certain that the commonest offenders are the foods, such as wheat, eggs, milk, chocolate, cabbage, onions, tomato and orange, which are eaten almost every day. It is this very fact that they are eaten almost every day that has so greatly retarded knowledge in this field. It is only the unusual patient who, without expert help, can discover that his breakfast cup of coffee or the toast that goes with it are responsible for such mild symptoms as flatulence or a stuffy head.

While waiting for the publication of more studies like those of Rowe and Vaughan, we decided to see what we could learn by questioning several hundred patients as to the foods which they had been forced to give up or which they could eat only with some distress.

THE NEED FOR CARE IN QUESTIONING PATIENTS

Obviously such questioning had to be done with care and discrimination. Too often, cross examination showed that some foods, such as cucumbers mentioned as indigestible had really never been touched because of their bad reputation, while other foods had not been touched for years following some occasion when they were blamed, perhaps unjustly, for a digestive upset. Accordingly, we have listed only such foods as were incriminated on what seemed to us to be fairly valid evidence, and whenever the type of answers given by an individual showed a lack of intelligence and judgment we stopped the questioning and rejected the data already obtained from this source.

It was found necessary also to ask specifically in regard to one food after another, because, time and again, the patient who first said he could eat everything told a different story when his memory was helped by perusal of a list of foods.

Unfortunately, also, patients are prone to blame, perhaps unfairly, the food that is tasted during belching or regurgitation. As W. E. Garrey⁴ once pointed out to us the fat in a meal must tend to gather in a layer, which floats on top of the fluids in the stomach. If onions have been eaten, the odoriferous essence will become dissolved in this layer of fat lying next to the cardia, and every time the person belches he will taste onions and will blame them for an indigestion that may have been caused by something else.

In many cases aversion to a particular food is of psychic origin and due to the patient's association of this food with some particularly unpleasant digestive upset of the past. In some of the persons questioned by us, even the thought, sight or smell of such a food caused nausea or belching. One man told of being nauseated by scrambled eggs, but he can eat them fried or poached, and, as is well known, many who eat cooked eggs cannot bring themselves to touch a raw egg.

We questioned more than 700 patients, most of them complaining of gastro-intestinal troubles, but we

⁴ Garrey W. E. Personal communication to the authors.

analyze here only the answers given by the first 500 intelligent or fairly intelligent men and women who admitted food sensitiveness and talked sensibly about it. In making some of the tables we were able to use only data from the last 400 records in which we took care to note the nature of the disturbances produced by the different foods.

THE FREQUENCY WITH WHICH SENSITIVENESS TO FOOD OCCURS IN THE GENERAL POPULATION

Before going on to tell how many patients we found sensitive to various foods, we feel we should warn the reader that the percentages given by us must be larger than those likely to be obtained through a study of an unselected group of persons, such as might be found in a restaurant. We dealt with selected patients, most of whom were suffering with indigestion and many of whom were seen by the senior writer because they complained of food sensitiveness or of symptoms that were thought to be due to it. Among those with an apparently functional type of indigestion there was hardly one who did not feel that he was sensitive to one or more foods.

According to Rowe,⁵ 31 per cent of 400 university students and nurses were sensitive to food, and in a house-to-house canvass of 508 villagers in Virginia, Vaughan³ obtained a corresponding figure of 62.6 per cent. Apparently, then, some idea of the percentages of the general public sensitive to the various foods can be obtained by multiplying our figures by some factor between 0.3 and 0.6. This factor will be the larger, the more intelligent the persons questioned and the more skilled and pertinacious the interrogator.

The physician who may wonder why he so rarely encounters food sensitiveness in his practice should remember that even the man of science tends to see only those things that he has been trained to see or that he is looking for, all else is likely to be missed or ignored or pooh-poohed.

THE MOST COMMON OFFENDERS

In all the lists published here it must be remembered that the frequency of appearance of a food must depend partly on the frequency with which it appears on the table of the average American. Obviously, then, the poor representation in these lists of a food like butter means much more than that quail or *pate-de-fois-gras* are not mentioned. This difference in the frequency with which foods are eaten may account for the fact that cauliflower and sprouts do not rank as high in table 1 as does cabbage.

The first thing to be noted in table 1, which sums up all the complaints made against the various foods, is that some of the most commonly eaten ones head the list. One patient in every four or five suffered discomfort after eating onions, apples, cabbage or milk. Certainly it does not look now as if an apple a day would keep the doctor away!

We can abundantly confirm the well known fact that many of the persons who cannot touch raw onions or apples can digest with comfort boiled onions or cooked apples. Curiously, most of the patients who dare not eat boiled cabbage are able to digest cole slaw and sauerkraut. One patient who has violent symptoms after eating boiled cabbage can eat it raw and another can digest sauerkraut only when it is not cooked.

Another striking fact to emerge is that chocolate is such a common offender, and, what is more, it is often a serious offender. The percentage given in the list should probably be larger, as it seems that a number of the persons who knew only that they must avoid sweets or candy were really sensitive to chocolate. In one case even the smell of chocolate causes sneezing. As will be seen later, this food seems to be the worst offender in cases of migraine.

One of the interesting points brought out by this study is the fact that pie and pastry, which have such a bad reputation, were rarely complained of and hence are not represented in our lists. The commonly despised fats and greasy foods were blamed by many persons, but often this may have been due solely to the fact that they were tasted at the time of belching.

CURIOUS OBSERVATIONS

Curiously, we found one person, a physician, who gets an attack of asthma after eating onions, raw or cooked, but who can eat them if they are first soaked in vinegar. Another patient who expected his statement to be received with incredulity, maintained that for him cucumbers with the rind on were harmless, it

Pork	7	104 other foods 1 per cent or less	

was only when peeled that they gave him distress. Another stated that for him, the harmful part of the apple was in the peelings.

It is hard to understand why, in one person so slightly absorbable a substance as agar should produce stiff and tender fingers. In another person the eating of bran brings pain in the jaw, and in another, a highly allergic girl, even a small amount of hydrocarbon oil, eaten inadvertently in mayonnaise, produces violent abdominal pain.

Seven patients knew that they could bring on attacks of asthma or vasomotor rhinitis by eating certain foods. Three others appeared to have become sensitive to food after cholecystectomy, and we wonder if changes in the flow of bile served to alter the permeability of the intestinal mucosa to intact foreign protein. Another person, however, lost much of his food sensitiveness after cholecystectomy. It is interesting that in several persons the eating of certain foods caused pain typical of cholecystitis.⁶

There were three cases of an ulcer-like syndrome due apparently to the eating of one or two of the following

foods banana, apple, "meat," cabbage, turnips and milk. In five other cases presenting a deformed duodenum, hunger distress was brought on by the eating of such foods as apple, tomatoes, milk, eggs, radishes, onions, pickles, sauerkraut and spinach. In one case, appendicitis was simulated by the eating of onions.

Eight patients attributed canker sores or sore tongue or burning in the mouth to the eating of certain foods,

TABLE 2—Severe Reactions of 500 Patients to Food, with Symptoms Such as Vomiting, Diarrhea or Severe Pain

Per Cent Cases		Cases	
Milk cream and ice cream	7 34	Peanuts	4
Chocolate	5 21	Pork	4
Apples (raw)	4 10	Strawberries	4
Onions (raw usually)	3 17	Raw fruits	4
Eggs	3 10	Lobster	4
Tomatoes	3 15	Veal	4
Cabbage (cooked)	2 12	Dried beans	4
Meat—beef and beef fat	2 11	Cucumbers	3
Corn	2 11	Oranges	3
Coffee	2 8	Radishes	3
Bananas	2 8	Sweets	3
Nuts	1 6	Peas	3
Caulliflower	1 5	Fats	2
Cantaloup	1 5	Peppers	2
Fish	1 5	Pickles and sour foods	2
Chicken and chicken broth	1 5	Spinach	2
Watermelon and melons	1 5	Oat meal	2
Cheese	1 5	Sauerkraut	2
Lettuce	4		

The following foods were each complained of once

Wheat	Chili peppers	Okra
Potato	Brazil nuts	Vinegar
Butter	Walnuts	Cranberries
Coco cola	Broccoli	Raspberries
Rhubarb	Shrimp	Asparagus
Sprouts	Oysters	Vienna sausage
Eggplant	Crab	Green beans
Mushrooms	Scallops	Garlic
Pepper	Grapes	

and food seemed to be responsible also for joint pains in five persons and for irritation of the bladder in three.

SEVERE REACTIONS

As Vaughan has wisely pointed out some of the foods that appear high on the list of those that cause trouble are only mild offenders in that the symptoms produced are belching, regurgitation, "tasting" or slight urticaria, which do not greatly inconvenience the victim. Other foods such as chocolate shell-fish or eggs when they do offend are likely to cause such serious trouble that the patient has to consult a physician.

Table 2 shows, in order of frequency with which complaint was made, the foods which produced such a troublesome reaction that the patient was compelled to avoid them. It is interesting to note that milk heads the list, and that seven in 100 persons seen by us were almost unable to touch it. From our figures it appears that perhaps nineteen more in 100 patients consulting a gastro-enterologist will not be able to take it with comfort. Three persons in every 100 questioned by us did not dare to eat eggs.

One of the most interesting observations is that only one person in the 500 questioned knew that he must not eat wheat, and, as we remember, this handicap had been pointed out to him by an allergist. If, then, the allergists are right, and wheat is the commonest of all seriously offending foods, it is apparent that patients, by themselves, practically never discover their sensitiveness to it.

MIGRAINE

A number of patients who suffered with migraine had discovered a relation between their attacks and the ingestion of food, they knew that the eating of certain foods would be followed by headache, but only a few had been able to cure themselves by restricting the diet. Unfortunately, in each case there were other causes at work besides food.

The most interesting feature to be noted in the list of foods complained of by migrainous patients is the fact that it is headed by chocolate. Following chocolate came onions, milk, peanuts, cabbage, eggs, pork, apples, coffee, cucumbers, "meat" and oranges. According to the allergists, the commonest offender in cases of migraine is wheat.

BAD EFFECTS OF FOOD ON THE NERVOUS SYSTEM, OTHER THAN THOSE SEEN IN MIGRAINE

One of the most interesting facts and one that should be brought forcibly to the attention of the medical profession is that in many persons the eating of certain foods has a disturbing effect on the nervous system producing not only headache but such symptoms as nervousness, irritability, sleepiness, drowsiness, dizziness, numbness "queer feelings," cold sweats, feverishness, and perhaps even some mental aberration. One patient seen by us was so benumbed mentally that for many years he was unable to work and spent his time going from one psychiatrist to another. Within a few days after the removal of fish and a few other foods from his diet "his head cleared" and he returned to work.

One of the most striking examples of what seemed to be a cerebral disturbance due to food was encountered in the case of a husky chauffeur who one evening did his best to eat a freezer-full of strawberry ice cream left over from a party given by his employer. About 2 a m his wife woke to find him unconscious and in violent convulsions which lasted for several hours. Next day there was an eosinophilia of more than 25 per cent. He had never had a convulsion before this.

TABLE 3—Foods Blamed by 157 Among 400 Patients Who Complained of Gas, Belching, Flatulence or Distention

	Per Cent of 157		Per Cent of 157
Onions	36	Strawberries	7
Cabbage	34	Pork	6
Apples	33	Meat and beef	6
Radishes	21	Bananas	5

Coffee	11	Peas	3
Lettuce	11	Prunes	3
Watermelon and melons	10	Sweets	2
Peanuts	9	Ginger ale	2
Eggs	8	Sour foods	2
Oranges	8	Sweet potato	2
Tomatoes	8	Beer	2

episode, and he was well for years afterward. Another patient in the group studied was almost freed from epileptiform attacks by the removal of beef from his diet.

Such observations should not be surprising when it is common knowledge among laymen that certain foods, such as cooked cheese, are likely to produce nightmares and restless sleep. Not infrequently the first comment of a patient who responds well to an elimination diet is "my head feels right again."

URTICARIA, RASHES AND ITCHING

Most interesting is the fact that 40 per cent of the patients who were subject to transient attacks of urticaria were unable to incriminate any particular food. As one would expect, strawberries head the list of the foods that were blamed, and after them come tomatoes, eggs, fish, milk, chocolate, meat, pork and oranges. In most of the cases of severe, almost constant urticaria, neither we nor the victim could pin the blame on any food.

TABLE 4—Foods Blamed by 98 Among 400 Patients Who Complained of Regurgitation, Lingering Taste or Repeating

	Per Cent of 98		Per Cent of 98
Onions	22	Caullflower	0
Radishes	20	Strawberries	6

Watermelon and melons	8	Salmon	3
Apples	8	Celery	3
Eggs	8	Beans	2
Tomatoes	8	Cheese	2
Coffee	7	Nuts	2
Oranges	7	Sweets	2

GAS, BELCHING, ABDOMINAL DISTENTION, REGURGITATION AND HEARTBURN

Table 3 gives the foods that most frequently seemed to be responsible for the production of gas, belching or distention of the abdomen. It is interesting that onions, cabbage, apples and radishes are to be found listed ahead of dried beans, which are commonly supposed to take first place. It is interesting to find milk in seventh place. It is possible that onions head the list on account of the fact already mentioned that when they have been eaten the belcher tastes them.

As one would expect, onions head the list of foods (table 4) that were blamed by patients as producers of regurgitation, usually because they could be tasted for hours after a meal.

It is interesting to note that the foods which were blamed for heartburn were somewhat different from those that were tasted for hours after a meal. This would indicate that the mechanism producing these two groups of symptoms is different. At the head of the list were tomatoes, onions, oranges, apples, radishes, coffee, pork, spices, cabbage and eggs.

ORIGIN OF AND PERIODIC VARIATION IN SENSITIVENESS

In a few instances the patient questioned during this study was able to trace his or her sensitiveness to a period of overindulgence in a particular food. Thus, one man in his student days ate at one sitting 2 pounds of dates left over from a fraternity party and thereby became highly sensitized to this food. Another became sensitized to milk by taking from four to six quarts a day during treatment for tuberculosis. After that small amounts produced nausea and diarrhea.

As was to be expected, many persons who could not eat full servings of certain foods were able to eat small amounts or they could eat these foods for one or two days but not for three. One patient who can digest one egg usually vomits when he eats two; another can eat eggs for four days in succession before he begins to regurgitate them; another can drink milk for three days

before getting an attack of migraine, and another can drink it for three days before his bowels become loose.

Several allergists have commented on the way in which sensitization comes and goes, so that at times the patient can eat a certain food with impunity and at other times it will make him sick.⁷ One of the patients studied by us has difficulty in digesting some foods only if she exercises after the meal.

TWO FACTORS COMBINING TO PRODUCE UPSETS

Some observations recently made indicate also that two sources of irritation, both constituting subliminal stimuli, may combine to produce serious trouble. Thus a woman of our acquaintance who is insensitive to wheat during the winter can avoid severe hay fever in the summer by excluding this food from her diet. Another patient becomes wheezy on exercising only if he is eating wheat.⁸

Similarly, fatigue, nervousness and psychic strain can at times so injure, perhaps, the absorptive power of the intestine that a food which ordinarily would cause some flatulence will produce violent diarrhea and mental dulness.

A LIST OF FOODS THAT SELDOM OFFEND

Once the most common offenders are well known, a complementary list of probable nonoffenders can be made, and this can then be used as the starting point of investigations into the food sensitiveness of individuals.⁹

Unfortunately, the list presented here cannot have great value until the foods on it have been tested by

TABLE 5—Number of Complaints Lodged Against Each Food During an Investigation of 400 Patients (Not Percentages)

Nuts (various kinds)	21	2	6	0	2	0

many patients. As we said before, the fact that a particular food is not found in tables 1 or 2 of this paper may mean simply that it is seldom eaten by persons living in the North Central states.

⁷ Rowe, Food Allergy, p. 29.

⁸ An introduction to some of the literature on this phase of the problem is given by Gelfand, H. H., Extra Pollen Hypersensitivity—An Important Consideration in the Treatment of Hay Fever, *Am J M Sc* 182: 81-86 (July) 1931.

⁹ Such a list may be found in Rowe, A. H., Food Allergy, 3rd Revised Edition, *Am J Digest Dis & Nutrition* 1: 387-392 (Aug.) 1934, and Vaughan, W. T., The Diagnostic Program in Food Allergy, *Am J M Sc* 182: 459-467 (Oct.) 1931.

Fortunately for the student of food sensitiveness, when a patient is markedly sensitive to one of the foods seldom eaten he is usually aware of the fact and can warn his physician not to include it in his first elimination diet. Presumably also the foods seldom used are the least likely to get into the blood in such large quantities as to produce sensitization.

For a supply of protein, the deviser of an elimination diet will depend largely on lamb and gelatin. Oysters and scallops might perhaps be added occasionally, because if the patient is sensitive to these foods he will probably know it.

The best fat is probably butter. If well washed, it can usually be eaten even by persons sensitive to milk.

Among carbohydrates, the most useful appear to be cane, beet or maple sugar and rice. Trial may be made also of rye, barley and arrowroot. Tapioca and sago might be more useful if they could be prepared tastily without milk and egg. Some persons who are moderately sensitive to wheat can eat a little highly dextrinized, thin toast or zwieback. Lima, soya or string beans might be useful especially as they contain needed protein. Perhaps cooked apple would be harmless in most cases. Pineapple juice might also be tried.

For vegetables, the patient will try perhaps beets, asparagus, peas, Irish or sweet potato, egg plant, turnips, parsnips, pumpkin and artichokes. For fruits he may try cooked pears.

Tea rarely seems to give trouble. Occasionally a person who is somewhat sensitive to milk will take with comfort buttermilk, boiled dried or curdled milk (junket) or cottage cheese. There is evidence to show that the lactalbumin of milk can be changed and rendered harmless by heat.

Usually a patient is kept on a narrow elimination diet for so short a time that no one need feel worried because it is not well balanced and not full of vitamins and salts.

ELIMINATION DIETS

In some ways the ideal elimination diet would consist of no food at all. If the symptoms continued during a fast, it would be obvious that foods were not at fault. If, however, the symptoms disappeared, foods could be tested singly, one after the other, until all were classified as harmless or hurtful.¹⁰

In order to spare the patient the annoyance of fasting, and in order to conserve weight and strength in the weak and the thin, it is customary now to give, at the start, a few foods that are not likely to cause trouble. When relief follows, the search for the offending food is then fairly easy. If relief does not follow, the physician must fear either that one or more of the foods in the basic elimination diet used is an offender or else that the disease is not due to the eating of food.

Physicians will find that the much traveled and intelligent "dyspeptic" will usually welcome enthusiastically this idea of searching for the offending foods. He is sick and tired of diets imposed *ex cathedra*, and he is much impressed with the logic underlying the new idea.

SUMMARY

Patients who ask for dietary advice usually get either indefinite or inadequate or antiquated information, or else a ready-made formula or list which may or may not fit their individual needs and idiosyncrasies. Unfortunately, today, most textbook writers and many

dietitians are so concerned with the vitamin content of foods that they ignore the matter of digestibility and refuse to make allowances for individual weaknesses.

Unfortunately also it is not easy for the physician to get trustworthy information as to the likelihood or unlikelihood that a given food will disagree with the eater.

The allergists have contributed much toward a solution of this problem. They are finding that the commonest offenders against health and comfort are the foods most commonly eaten, such as wheat, milk, eggs, chocolate, cabbage, tomatoes and oranges.

Not all food sensitiveness is on an allergic basis. There appear to be many druglike substances in food that can cause irritation of the bowel or even disturbances at a distance from the abdomen. The largely indigestible cellulose in many foods is another factor in causing discomfort.

This paper is based on answers obtained on questioning 500 patients of fair or good intelligence who were for the most part complaining of indigestion. They were asked about the foods that they could not eat or could digest only with discomfort. With the exception of wheat which was mentioned once, the foods complained of were those already incriminated by students of allergy. Many of the patients suffered after eating onions, apples, cabbage or milk. Other common offenders were chocolate, radishes, tomatoes, cucumbers, eggs, fats, cantaloup, beef, strawberries, coffee, lettuce, dried beans, cauliflower, melons, pork, corn and pickles.

Because most of the persons studied were seen because they were suffering with indigestion, the percentages given here must be considerably higher than those obtainable in an unselected group of persons.

Seven patients in 100 were unable to drink milk because the distress produced was so severe, three in 100 could not eat eggs.

A number of patients with migraine had recognized a connection between the headache and the eating of certain foods such as chocolate, onion, milk, peanuts, cabbage and eggs.

Food can at times produce mental depression, drowsiness, and a number of curious sensations in the head.

Transient urticaria was commonly ascribed by the patients to the eating of strawberries, tomatoes, eggs, fish, milk and chocolate. Constant urticaria seldom seemed to be due to food.

Onions, cabbage, raw apples, and radishes were rated above Boston beans as makers of gas. Milk also was a common offender.

Two factors may combine to produce symptoms in some persons, one coming from food and another perhaps from pollen, dust, fatigue or emotion.

A list has been made of the foods that are seldom mentioned by patients with indigestion. These foods, which are probably fairly innocuous, can be used as a basis for the "elimination diet" with which the physician and patient can narrow down their search for offending foods. The substances suggested for trial are lamb, gelatin, butter, sugar, rice, rye, barley, arrowroot, tapioca, sago, lima or soya or string beans, cooked apple, pineapple juice, beets, asparagus, peas, Irish or sweet potatoes, eggplant, turnips, parsnips, pumpkin, artichokes, cooked pears and weak tea.

The idea today is not to warn only against greasy foods or to hand out a ready-made diet list but to fit a diet to the individual. Often by such study it can be shown that the nature of the diet has nothing to do with the indigestion complained of.

¹⁰ Alvarez, W. C. Ways of Discovering the Foods That Are Causing Indigestion. Proc. Staff Meet. Mayo Clin. 7: 443-446 (June 27) 1932.

CENTRAL FRACTURES OF THE
NECK OF THE FEMUR

AN ANALYSIS OF THE END RESULTS

J S SPEED, MD

MEMPHIS TENN

A great deal of confusion still exists in regard to the results obtained in the treatment of central fractures of the neck of the femur. This is unquestionably the result of a lack of uniformity in the methods of compiling the statistics and explains the otherwise impossible disparity in the published results which vary from 20 to 90 per cent in which bony union is obtained. In other words, for figures to be of value one must know exactly how the cases were selected, under what circumstances they were treated and on what criteria the assumption of bony union was determined.

It is fairly well conceded that the reports of end results in central fractures of the femoral neck which are properly and accurately compiled average about from 55 to 60 per cent solid bony union.

My colleague Dr Willis C Campbell has recently compiled an analysis of all our fractures about the hip joint. In this classification of true central fractures of the neck of the femur, excluding impacted or incomplete fractures, the end results showed 53.3 per cent solid bony union. These cases were all treated by the Whitman method and were personally observed for a minimum period of two years. The mortality was 12

per cent. These figures correspond with other published results.

In view of the work that has come out in the last ten years, especially the articles of Phemister and of Santos regarding aseptic necrosis of the femoral head following fracture of the neck of the femur, it was thought that a study based on these facts might give interesting data regarding the cause for the high percentage of nonunions. Consequently a series of 100 acute complete central fractures of the neck of the femur adequately treated and traced to a final determination as regards union or nonunion

in which it became necrotic and to determine, if possible, the bearing this had on union or nonunion.

Roentgenologic and histologic study of the femoral heads removed during reconstructive operations in cases from this series and from other cases will be used to illustrate and confirm the conclusions drawn.

A tabulation of the results in this series showed 52 per cent solid bony union and 48 per cent nonunion.

There has been a great deal of controversy regarding the causes of nonunion in fractures of the neck of the femur, the more common explanations given may be discussed under the heads of improper or incomplete reduction, insufficient immobilization and aseptic necrosis of the femoral head.

IMPROPER OR INCOMPLETE REDUCTION

There is no question that improper or incomplete reduction is a common cause of nonunion in cases improperly treated. It cannot be consid-

ered as an important element in this series, however, as the cases were all treated by the Whitman method which, in the hands of those accustomed to its use, is generally conceded to effect an accurate apposition of the fractured surfaces. The reliability of this statement is substantiated, both by the postreduction roentgenograms in the closed cases and by the visual demonstration, which may be obtained in those cases treated by open reduction. We have operated on a number of acute fractures recently for the purpose of using some type of internal fixation. In each of these cases the Whitman manipulation has been carried out with the head and neck under direct vision and it is very comforting to see the accuracy of the reduction and to know that certainly in the average case there is sufficient apposition of the fractured surfaces to permit bony union. The introduction of the lateral views of the hip the technic for which has recently been perfected, is a further check and help in closed reductions.

INSUFFICIENT IMMOBILIZATION

There is unquestionably some motion permitted between the fragments in a fractured hip even in a double spica cast. This is particularly true in obese patients after the cast has become loose. How seriously this affects the apposition of the fragments and the formation of callus can be judged by the number of cases in which the roentgenogram shows displacement immediately after removal of the cast. It has been our experience that, in those cases in which the head is living and in which union is progressing satisfactorily, the position is almost uniformly held satisfactorily. In those cases in which apposition has been lost it will usually be shown, either at the time or subsequently that other factors such as necrosis of the head and absorption of the neck account for the displacement. Again it is a common observation to find excellent apposition of the fragments on removal of the cast, which later is lost when immobilization is removed. Here the cast has maintained position in spite of the fact that union has not occurred.

Fig 1 (case 1)—Mrs S R D had a central fracture of the neck of the femur ununited of five months duration. The illustration shows a head with corresponding atrophy in the head and trochanteric region, indicating a living head. (In the illustrations it has been extremely difficult to reproduce the contrast in density between the head and trochanteric regions which is clearly evident in the original roentgenograms.)

was selected. Incomplete or impacted fractures, and those cases in which death occurred or which were lost sight of were discarded.

Basing conclusions on the evidence afforded by the roentgenograms I made an effort to divide the series into those in which the head remained viable and those

Fig 2 (case 1)—Head removed at reconstruction operation showing symmetrical atrophy.

Consequently, while incomplete reduction and inefficient immobilization may account for a small percentage of the cases treated by the Whitman method, one must look further for the fundamental cause producing such a high percentage of nonunions

ASEPTIC NECROSIS OF THE FEMORAL HEAD

A careful roentgenologic study of the femoral heads in sixty cases of nonunion, and microscopic studies of

Fig. 3 (case 1) —Section showing junction of the articular cartilage with the medullary cavity. Both the cartilage and the cells in the medulla are living

those heads available lead to the very definite conclusion that the vast majority of nonunions are the result of an aseptic necrosis of the femoral head. Deprived of the major portion of its blood supply, it does not receive sufficient nourishment to maintain the viability of its cellular elements

Clinical recognition of the fact that the femoral head undergoes necrosis following central fractures of the femoral neck dates back to the time of Sir Astley Cooper, approximately 100 years ago. Kocher in 1896, basing his conclusions largely on clinical observation, stated that in all fractures of the femoral neck the head became necrotic

It has been only in the last ten years that the earlier clinical observations regarding the process of aseptic necrosis have been placed on an accurate scientific basis and that a complete pathologic description of the process of necrosis with subsequent revascularization and substitution has been given

Schmor, Hesse and Bonn were among the earlier investigators to describe the process of secondary revascularization. Phemister has recently contributed valuable studies on the general subject of aseptic necrosis. The comprehensive article of Santos which was published in 1930, reviews the entire subject and, using the data gathered from the study of a series of femoral heads removed at autopsy or operation, clearly describes the entire pathologic process, correlating the clinical, x-ray and microscopic changes

In attempting to estimate the number of heads in this series which became necrotic, it was necessary to rely almost entirely on the x-ray evidence, as in only a few cases were the heads obtained for microscopic study. It is realized that even though the roentgenograms were all taken at the same place with a routine technic there still remains a probable percentage of

error due to the element of personal equation in interpreting the comparative density of the femoral head and the adjacent bone. It is on this variation in density that distinction between the viable and the necrotic heads is made

It is frequently impossible to determine the viability of the head from a single film, but in most instances if the cases are followed over a sufficient period of time with successive roentgenograms, a very definite decision can be reached

In every case in which it has been possible to check the x-ray reading with the microscopic examination of the head they have been found to coincide. Based on the roentgenologic evidence, it was found that the head was necrotic in 34 per cent of this series of 100 acute fractures of the femoral neck. In thirty cases nonunion occurred. Granting that the average series reported will show 40 per cent of nonunions, it is apparent that approximately 75 per cent of our nonunions can be explained on the basis of aseptic necrosis of the femoral head

SOLID BONY UNION WITH VIABLE HEAD

Cases that are progressing to a solid bony union with a viable head show definite characteristics at the end of the routine three months period of cast immobilization. Roentgenograms show the normal relative position of the head and neck to have been maintained. The density of trochanter, neck and head are approximately the same, each having undergone the usual physiologic atrophy that characterizes bone with a normal blood supply

At this time it should be possible to form a fairly definite idea as to the probable prognosis in each case. Variations from the

normal should be viewed with apprehension. It is true that some cases will go on to solid union after slight displacement of the fragments or after absorptive changes in the neck but they are unusual. Even though perfect anatomic alignment has been maintained definite contrast in density between the head and the distal neck fragment and trochanter should make the prognosis guarded. There have been a number of such cases in this series in which the head proved to be necrotic, the apparent union disintegrating as soon as immobilization was removed and a typical nonunion resulting

Fig. 4 (case 2) —Mr. H. B. G. had a central fracture of the neck of the femur with nonunion of nine months duration with aseptic necrosis of the head. The trochanter and acetabulum show normal physiologic atrophy producing a definite contrast in density with the head which has retained its original density

Definite evidence that bony union has taken place is first shown by the reformation of the lines of force extending from the neck across the fracture line into the head. If the normal anatomic relationship between

the head and the neck has been maintained, these lines assume the same location and arrangement as those of the normal hip, but if the neck has become shortened or a coxa vara deformity has occurred, these reinforcement lines will follow the lines of greatest mechanical force.

The final evidence of union is shown by a gradual recalcification of the head, neck and trochanter as function and weight bearing are resumed.

Forty-eight per cent of this series obtained solid bony union with viable head.

Fig 5 (case 2)—Aseptic necrosis of head. The normal density has been retained except for small areas of early replacement changes.

NONUNION WITH LIVING HEAD

In improperly treated cases nonunion in the presence of a viable head is a common occurrence. It is easily explained by failure to secure or maintain apposition of the fragments.

That it is relatively infrequent in cases treated by the Whitman method is clearly shown by the fact that only 7 per cent of the cases in this series showed nonunion with a living head. Here again the conclusions were based on x-ray evidence, only one living head having been available for microscopic study.

If the head, neck and trochanter showed a uniform decrease in density, or if the head showed a regular symmetrical atrophy as shown by successive roentgenograms during the first six months following the fracture, it was considered viable.

The accuracy of the x-ray deductions is supported by the fact that the one head removed showed unchanged marrow cells and living bony trabeculae in the microscopic sections and that in two other cases union was obtained following bone grafting.

Bony union associated with a necrotic head occurred in 4 per cent.

It is clearly evident, both from cases observed in this series and from those reported by other authors, that union may, and does take place between the living distal fragment and a necrotic femoral head. Ahausen explains this by the formation of a bridge of connective tissue and callus extending from the distal fragment across the fracture line and into the necrotic head. The head later undergoes revascularization and eventually replacement by newly formed bone and cartilage.

Santos states that "in none of the cases here reported was there any evidence either histologic or roentgenologic that the new bone formed in connection with the blood vessels entering the head by way of the fovea played any part in the healing of the fracture."

It must be concluded, then, from the evidence at present available that union under such conditions is entirely the result of an outgrowth of living elements from the distal fragment that invade the necrotic tissues of the head. This new growth or bridge consists at first of the same young connective tissues and blood vessels seen in the early substitution of the head. Later new living bony trabeculae grow out from the distal portion of the neck, crossing the fracture line and extending up into the head.

Santos reports a case of an impacted fracture of the femoral neck which came to autopsy four weeks after the injury, in which histologic sections taken across the fracture line showed new bony trabeculae extending from the distal portion of the neck into the necrotic trabeculae of the head.

It does not seem improbable that they may here blend with the new bone formed in the process of substitution of the necrotic head.

It must be assumed that in such cases, if one is to obtain a satisfactory functional result, a complete substitution must be made for the necrotic head, which must be replaced by living bone and cartilage. Otherwise degenerative changes with subsequent erosion and fragmentation of that portion of the head which is not so replaced will occur on the resumption of weight bearing.

With present knowledge and methods of observation, it is impossible to determine when this process of substitution has progressed sufficiently to allow the resumption of function. It is probable that in many cases it never does occur and that years after unquestionable bony union has taken place between the neck and the necrotic head trophic changes with complete disintegra-

Fig 6 (case 2)—Section showing characteristic aseptic necrosis of the head with early replacement changes. Normal marrow cells have disappeared being replaced here and there by early fibrous tissue with some new blood vessels. The bony trabeculae are necrotic.

tion of the head may occur. This is illustrated by the following two cases.

Two and one-half years after a fracture of the femoral neck, unquestionably ununited, the patient returned because of pain in the hip. She had been walking without support for two years. Roentgenograms showed the old fracture united in good position but with degenerative changes throughout the head and beginning disintegration.

Another patient, Mrs. C. C. J., had a fracture of the femoral neck, which apparently united normally except for a persistent

contrast in density between the head and the trochanter. She resumed walking and, except for occasional pain in the hip, was free from symptoms for four years, at the end of this period she returned because of disability in the hip. Roentgenograms at that time showed complete disintegration and fragmentation of the head. The union in the neck remained solid.

Union with a necrotic head is of relatively infrequent occurrence, being present in only 4 per cent of this series. In these cases the x-rays showed persistent con-

nosis in such cases. However, a careful study of the roentgenograms invariably revealed an increasing contrast in density and usually beginning substitutive changes in the heads. In no case did the lines of force reform across the fracture line.

It has been stated by Santos that the process of revascularization and substitution of the necrotic heads begins within the first month and is usually evident in the roentgenogram at three months, but in some cases the process is much delayed and may not occur for years.

Studies of the heads in this series are entirely in accord with this statement. The majority did not show definite substitution as shown by the x-rays, under six months; in many it was not present until one year. In some old cases seen because of disability from nonunion heads have been observed which maintained their original density for four or five years.

The period of time that the necrotic head retains its appearance of uniform density depends on the rapidity of secondary revascularization and replacement of the necrotic bone elements by newly formed fibrous tissue and living bony trabeculae.

When the head is detached from the distal fragment the first evidence of replacement usually appears around the focus and is produced by an ingrowth of blood vessels and young connective tissue, either from the vessels of the ligamentum teres or from a pannus-like growth of connective tissue which covers the outer surface of the articular cartilage and enters the head by way of the focus. The same pannus covers the fractured surface of the neck and begins an invasion of the necrotic head from this location.

Revascularization and replacement of a necrotic head is shown in the roentgenogram by irregular areas of decreased density which increase in size as the process continues until the greater portion of the head may be replaced by living tissue which differs little in density from the living atrophic head. It can usually be dis-

tinguished from the living head, however, by the fact that the structure of the living head is much more regular, but in some old cases this distinction is impossible.

NONUNION ASSOCIATED WITH NECROTIC HEADS

It is usually possible at the end of the three months period of cast immobilization to determine by the roentgenographic appearance whether the head is necrotic or viable. In this series of 100 acute fractures the contrast in density between the head and the trochanter was sufficiently clear in twenty-four cases after three months to warrant the conclusion that the head was necrotic. The contrast in density is first evidenced as an absorption of the lime salts in the distal portion of the neck and the trochanteric region. Having an adequate blood supply this portion of the bone undergoes the normal physiologic atrophy of disuse. The head, deprived of its blood supply, does not show in this atrophy, retaining approximately the same density that it presented at the time of fracture. Subsequent roentgenograms showed that all but two of these cases resulted in nonunion.

In eleven cases a definite conclusion could not be drawn from the roentgenogram at three months. Eight of these subsequently proved to be necrotic, six resulting in nonunions.

In a number of cases in the nonunion group the normal anatomic relations between the fragments was maintained for months after immobilization had been removed. The apparent union disintegrated only when direct weight bearing was begun.

Relying solely on the maintenance of position, one would have been greatly deceived as regards the prog-

Fig 7 (case 3)—Mrs. T. L. D. illustrating impacted or incomplete fracture eventually resulting in nonunion with a necrotic head. *A*, original appearance at time of fracture showing incomplete fracture without displacement. *B*, four months later showing definite contrast in density between atrophic trochanter and the necrotic head which has retained its original density. Normal position of the fragments has been maintained. *C*, sixteen months after injury showing typical nonunion with displacement of the fragments and a necrotic head.

Fig 8 (case 4)—Mrs. C. C. J. had a complete central fracture of the neck of the femur adequately treated resulting in solid bony union with a necrotic head which later completely disintegrated on resumption of weight bearing. This case shows that even though union may be obtained with a necrotic head, subsequent degenerative changes may occur unless the head is completely revascularized and replaced. *A*, complete central fracture of the neck of the femur with the usual displacement of the fragments. *B*, one year after injury, solid bony union with normal relation of the head and neck fragments; also atrophic changes in the head, trochanter and neck with retention of the original density in the head indicating union with a necrotic head. *C*, six years after fracture, complete disintegration and fragmentation of the head.

Microscopic sections have been made on nine femoral heads removed at operation, some of which are cases included in this series. Eight of the heads were necrotic and one was viable. The changes seen in these heads corresponded accurately to the roentgenographic appearance and in each case corroborated the preoperative diagnosis as regards the viability of the head. The pathologic changes were the same as those described by Santos and will not be repeated here. With the roentgenologic evidence as a basis for conclusions, it is possible to state from this series that one may expect approximately 35 per cent of the femoral heads to become necrotic following central fracture of the neck of the femur. Thirty per cent will result in nonunion.

Assuming that failures in the average reported cases are 40 per cent, it is possible to explain 30 per cent, or 75 per cent of the nonunions, on the basis of aseptic necrosis of the head. This is a factor over which one has no control with present methods of treatment and must remain as an irreducible minimum unless some method is discovered of reestablishing or improving the blood supply to the head.

It is possible that some of the recent methods of open reduction and internal fixation used in the acute fractures may accomplish this by a more accurate and constant coaptation of the fragments, a reestablishment of circulation being permitted before necrosis of the head occurs. Knowledge gained in the treatment of the acute fractures is a valuable guide in determining the type of operation to be employed in cases of definitely established nonunion.

If the head is viable, union may be induced and a satisfactory functional result obtained in many cases by a bone graft or some other method of internal fixation, even years after the fracture.

Smith-Petersen reports a remarkable case in which union was obtained by means of a nail ten years after the injury.

Practical experience has shown that in the presence of a necrotic head it is difficult to restore union by bone grafts or any other method of internal fixation. Such operations result in failures almost as a routine, either because of failure to induce union or because of degenerative changes appearing later in the head.

It is apparent, then, in cases of nonunion with necrotic head, that a reconstruction operation offers the patient the best prognosis.

869 Madison Avenue.

Flying in the Face of Nature—The point of view that plants and animals including our own bodies are nature's wholes which have evolved in relation to each other can help us in grasping two important facts. One is that we are 'flying in the face of nature' and shutting our eyes to one of the plainest implications of the evolutionary point of view when we take our nourishment too largely in artificially refined forms—in forms from which we have rejected parts of those wholes to which we are attuned by evolution. And the other of these facts is that if we plan our dietaries to meet all our known nutritional needs and meet these by the use of reasonably natural foods these, as nature's wholes of the kinds to which our own bodies have been adjusting themselves throughout our evolutionary history, will almost certainly furnish any substances which may be essential to our nutritional well being though still scientifically unknown to us. This is not to suggest a return to nature but only an intelligent application to the problem of food and health of one of the simplest and most fundamental implications of the general evolutionary and scientific point of view of today.—Sherman H. C. *Food and Health*, New York: Macmillan Company, 1934.

CORONARY THROMBOSIS

FOLLOW-UP STUDIES WITH ESPECIAL REFERENCE TO PROGNOSIS

WARREN B. COOKSEY, M.D.
DETROIT

A more convincing physiologic experiment could scarcely be devised as illustrative of the recuperative power of the human heart than the restoration of cardiac function following acute coronary occlusion. That it is possible for the human heart to reestablish its intrinsic blood flow, both through collateral vessels and through channels other than the coronary tree, is now well established and undoubtedly is an important factor in aiding recovery in cases of cardiac infarction. Allbutt,¹ Wearn,² Scott³ and others have reported cases of complete occlusion of the coronary orifices from syphilitic aortitis in which no serious myocardial change was present. In these cases a gradual occlusion of one or both coronary orifices over a period of months was so completely compensated for that the patients were able to continue their daily work with comparative ease. It is quite apparent, therefore, that if the initial shock of acute cardiac infarction is not too great and the first few weeks are survived, many patients will recover so completely and the coronary circulation will so thor-

TABLE 1—Duration of Condition in Thirty-Two Living Patients (61.4 Per Cent of Total)

oughly reestablish itself in time that many useful years will remain to the individual. Such an optimistic outlook for cardiac infarction is, however, not very general among the medical profession and, it seems to me, is badly in need of emphasis.

The basis for this study and for the preceding note of optimism is a series of private cases seen over a period of seven years. No case has been used which did not show positive evidence of infarction, with clinical and electrocardiographic data to substantiate amply the diagnosis. Very mild or questionable cases have been rejected. In all, fifty-three cases have been studied.

In table 1 are shown the living patients grouped according to the time that has elapsed since the initial attack. A few details warrant further elaboration. In the thirteen year group, one case is listed. This man, a real estate operator, suffered a most severe infarction at the age of 61 and during the past four years has had occasional mild attacks of acute pulmonary edema following moderately strenuous exertion. However, in the thirteen years elapsed, he has continued steadily to earn his livelihood, drives his own car and goes up and down stairs without discomfort.

From the Freund Clinic.

In the six year group, ten patients are living. Of these, seven are well and have been restored to their previous occupation. Of the three not working, one is a man, aged 75, who has diabetes and tabes but absolutely no cardiac difficulties. The second is a retired physician, aged 70, who is able to walk long distances and who, two weeks ago, was sufficiently well to remove an old stump from the grounds of his summer cottage. It is of interest that he worked for nearly three hours

with a pick and spade, and in his own words was wringing wet with sweat but hadn't a single symptom referable to his heart. The third of the inactive patients in this six year group has become a chronic invalid at 55, more functionally ill than otherwise. During the six years she has had a thyroidectomy for adenoma, a cholecystectomy for common duct obstruction and numerous hospital entries for various minor complaints. She walks stairs as desired, however and does not suffer significantly from her heart. I will not detail further the patients in this group, but the foregoing four cases are representative and illustrate very well how much a restoration may be expected in some cases.

In table 2 is enumerated the number of living patients who have been restored to their previous occupation. Only seven, or 21.9 per cent, have not been so restored, and of this group three are able to drive their own cars at the ages of 52, 67 and 70. Of the four who are less active, one includes the neurotic patient already discussed, while three are aged 75, 74 and 74. It would seem, therefore, that there is even some basis for optimism in this inactive group. As noted, 75 per cent of all living patients are free from symptoms. Of the eight patients who have mild symptoms of stenocardia or dyspnea, four are working and four are inactive.

Table 3 covers the electrocardiographic changes in these cases at the present time. Only three cases in this group do not show evidence of coronary disease, and it is instructive that in not one of these three cases were there attacks associated with shock or marked by the more usually severe reaction on the pulse and blood pressure. The high incidence of persistent changes in the electrocardiogram for many years following cardiac infarction is an important finding and is just beginning to be recognized. As has been previously reported, the more common persistent changes are RT alteration, curve negative T₁ or T₂, or diphase T₁ or T₂. While a prominent Q_s was present in 16.6 per cent of this group, it was not present alone in any case. From these data I feel justified in concluding that for the remainder of these patients' lives following coro-

nary thrombosis approximately 90 per cent may be expected to have electrocardiographic evidence of coronary disease. This should prove of distinct value in the evaluation of etiologic factors in individual cases of heart disease.

In table 4 are listed the occupations of the active group who have survived a coronary thrombosis. This list I have included merely to illustrate that such patients are able to carry responsible positions, entailing not a little physical and mental strain, with no apparent harm to themselves.

Table 5 is of interest chiefly because of the age groupings. It will be noted that the average age of this fatal group is 63.4 years, while the average age of the living group is only 54.2 years. It has often been contended by students of this subject that individuals above 60 years of age tolerate acute coronary occlusions better than those below 60 years of age. This study does not bear out such a contention and would seem much more in harmony with clinical experience in which other circulatory insult is tolerated less well by such elderly patients. As indicated by the chart, only two patients died two months after the occlusion, the greater majority succumbing within a relatively few days. Several cases in this fatal group warrant some elaboration.

CASE 1—A man, aged 35, was stricken with a most severe attack in which auricular flutter quickly resulted. He was hospitalized and the flutter and decompensation were controlled. After two months his condition was quite satisfactory and he was allowed to work a few hours each day managing his butcher shop. Two years elapsed and the depression came, so that he began to do all his own work, lifting heavy loads and making trips up and down stairs. He soon began to have attacks of precordial pain which he would not heed, and a few weeks later was found dead in his bed.

CASE 2—A salesman, aged 44, had a moderately severe attack, but after the third day he refused absolutely to say in bed. On the tenth day he attempted to go to the bathroom, where he collapsed and died immediately.

TABLE 4—Occupations of Active Group

Merchant	8	Attorney	1
Housewife	4	Printer	1
Physician	2	Engineer	1
Broker	3	General agent for life insurance	1
Sales manager	2	Accountant	1
Bill collector	1		

TABLE 5—Analysis of Twenty One Fatal Cases (39.6 per Cent Mortality)

Average age of all patients at death 63.4 years			
Age Group	Number	Fatal Cases per Cent	
60-70 years	15	71.5	
50-60 years	4	19	
35-50 years	2	9.5	
Patients dying few hours to 2 months	19	90.5	
Patients dying after 2 months	2	9.5	

CASE 3—A housewife, aged 70, had a very severe attack and for six days was unconscious. On the thirtieth day after the attack, although she was still mildly decompensated, she refused to stay in bed any longer. Orthopnea and edema developed within a few weeks and she was again persuaded to stay in bed for a time. She was never entirely free of decompensation, however, and died eight months after the infarction.

Such histories as these, I believe, are most significant, for they indicate that many patients with coronary occlusion might be saved who are now succumbing. Of recent years I have adopted the policy of very early enlisting the patient's full cooperation in remaining

absolutely at rest in bed for a minimum of six weeks following the attack. After this, another six weeks elapses before any resumption of activity is permitted, and careful supervision of the patient's activities is continued for a full year. If a sensible explanation of the exact mechanism of coronary occlusion, with the necessity for healing of damaged tissue, establishment of collateral circulation and the opening up of the thebesian channels is given in understandable terms, I believe that few patients will refuse to obey orders. I fear a great deal more any overactivity in the early weeks than the possibility of a later cardiac neurosis.

CONCLUSIONS

Fifty-three cases of acute coronary thrombosis, with a mortality of 39.6 per cent, have been studied from private practice. Of the thirty-two living patients, 78.1 per cent have been restored to their previous occupation, with one patient living thirteen years after acute infarction and ten patients living six years after the onset of infarction. The electrocardiogram is positive for coronary disease at the present time in 90 per cent of these cases. The mortality of the patients suffering occlusion at the age of 60 and above is distinctly higher than is the case at ages below 60. A much more hopeful prognosis seems justified on the basis of these studies than is generally prevalent. Of great importance is a period of many weeks' convalescence, with appropriate restrictions for a full year following acute coronary occlusion.

MYASTHENIA GRAVIS

EFFECT OF TREATMENT WITH ANTERIOR PITUITARY EXTRACT. PRELIMINARY REPORT

HAROLD E. SIMON, M.D.

BIRMINGHAM, ALA.

Myasthenia gravis is a rare disease characterized by excessive fatigability of muscles, especially marked in certain characteristic groups. The ocular muscles are usually first involved and there is unilateral or bilateral ptosis of the eyelids, diplopia, occasionally strabismus and a fixed eyeball, which makes it necessary for the patient to turn the body rather than the eyes in order to see objects at one side. The muscles of mastication and deglutition are frequently involved early, and the jaw sags soon after the patient starts to chew. There is strangling and difficulty in swallowing. The voice weakens rapidly, the muscles of expression tire and a masklike expression results. In more severe cases there are attacks of rapid, shallow breathing when the accessory respiratory muscles or the diaphragm are involved, and weakness of the cardiac muscle may result in palpitation and tachycardia. The involvement of the muscles of the trunk and upper and lower limbs later and in more severe cases may produce weakness and helplessness so marked in some instances that the patient is unable even to turn over in bed.

The onset of myasthenia gravis is usually gradual and the course is progressive over a period of from several to twenty or more years. Remissions are so frequent that they are regarded as a part of the disease, especially in the milder and more prolonged cases. More rarely the onset may be acute and the course rapid, resulting in death within a few weeks. Untreated, the outlook is grave, death resulting from strangulation, inanition and dehydration or secondary complications.

Spessard¹ reported twenty-six deaths in thirty-eight cases while under observation.

Constant or significant pathologic changes have not been observed either clinically or at necropsy. There is wasting of the muscles from poor nutrition, but no constant or marked changes are demonstrable in the neuromuscular mechanism. Weigert demonstrated lymphocytic infiltrations in the muscles. Abnormalities in the thymus gland in patients who have died from myasthenia gravis have been noted in some instances. The constancy or significance of neither of these changes has been shown.

Since the first descriptions of the disease by Wilks, Erb, Goldflam, and others in 1877, 1878 and 1891 respectively, some 300 cases have, according to Keschner and Strauss,² been reported in the literature up to 1927. Boothby³ in 1934 reported the largest individual series, which consisted of forty-seven cases observed in the Mayo Clinic over a period of twenty-six months.

Previous to 1930 no treatment of any value was known. The importance of rest and the necessity for the maintenance of nutrition were recognized. Strychnine has been given for many years and in large doses was thought to be beneficial. Arsenic, thyroid extract, parathyroid preparations, calcium, thorium and roentgen exposure over the thymus gland have all been employed with indifferent results.

In the last four years two significant discoveries have been made in the treatment of myasthenia gravis. Harriet Edgeworth⁴ in 1930 reported the beneficial effects of large doses of ephedrine in her own personal case of myasthenia gravis. She used three-eighths grain (0.025 Gm.) doses of the drug twice daily. This results in prompt alleviation of symptoms in many instances, but the improvement is not always constant and, according to Boothby, excessive amounts may not only cease to allay the symptoms but even appear to aggravate the weakness and produce intense nervousness.

In 1932 Remen in Germany and Boothby⁵ in this country reported beneficial effects from the ingestion of aminoacetic acid (glycine or glycoll), which is the simplest of the series of amino acids and is present in gelatin. This suggestion was based on the work of Milhorat and others, who first noted disturbed creatine metabolism in progressive muscular dystrophy, and on the observation that of all the amino acids aminoacetic acid produces the greatest increase in creatine excretion in the urine. The results of treatment with aminoacetic acid have been encouraging. Boothby contrasts the twenty-six deaths in thirty-eight cases reported without details by Oppenheim, with the results in forty-seven cases treated with aminoacetic acid and ephedrine at the Mayo Clinic over a period of twenty-six months. In the latter series thirteen of the patients were able to work practically at full time, nine were greatly benefited, seventeen were moderately improved, one was not heard from, and seven died. Of the seven patients who died, two abandoned treatment, one died within

forty-eight hours after coming under observation one died from pneumonia one committed suicide, and two had failed to show any improvement under treatment.

The results of treatment with aminoacetic acid, in some instances combined with ephedrine, are definitely encouraging and are vastly superior to the results of any previous method of treatment, they fall short, however of being entirely satisfactory. There is still a large group of cases in which recovery is incomplete and a small group in which this treatment is entirely without avail. For these cases there has hitherto been no therapeutic alternative.

Since July 2, 1934 I have used injections of anterior pituitary extract⁶ in treating two cases of myasthenia gravis, the results have been surprisingly good.

CASE 1—A woman aged 31 had a negative past history except for diphtheria at the age of 5 years. The onset of the present illness was in 1923 while she was three months pregnant, headache, double vision, ptosis of the left eyelid and slight dizziness appeared. Later there was bilateral ptosis and general weakness. When she played the piano the fingers and hands became powerless after a few minutes when she ate the jaws tired quickly and had to be assisted with the hand. The face felt stiff. The condition became progressively worse with slight remissions. In 1927 she was confined to bed and the diagnosis of myasthenia gravis was made by Dr. G. C. Anderson of New Orleans. Another remission occurred and she was nearly normal until 1933 when the symptoms recurred. At this time there was considerable respiratory difficulty on occasions with rapid shallow breathing and palpitation. Muscular aching was noted especially in the chest and shoulders. She was confined to bed except for a few hours each day and wore a patch over one eye to avoid the double vision. Difficulty in swallowing was noted, the voice rapidly weakened and she stuttered. She had lost weight and was unable to eat much on account of weakness of the jaw muscles.

On examination she appeared slightly undernourished and very weak. A patch was worn over one eye, the face was somewhat expressionless, the left eyelid drooped. When she walked she supported herself along the wall and on furniture and on several occasions she had to be assisted about the room. The reflexes were normal. The blood pressure was 115 systolic 75 diastolic. The urine appeared normal, the blood Wassermann reaction was negative and the basal metabolic rate was minus 14.

Ephedrine, even in small doses produced such marked nervousness that she refused to take it. Aminoacetic acid was not given. July 2, 1934 daily subcutaneous injections of 1 cc of anterior pituitary extract were started. After the second day all muscular discomfort disappeared. After the third or fourth day she was able to remain up out of bed nearly all day, and after the tenth day no symptoms whatever remained. Treatment was stopped for eight days and all symptoms returned. July 28 the injections were again started and continued at daily intervals for about ten days and then every two or three days until November 15. The symptoms promptly cleared up as they had done at first. She stated that she felt better than at any time since 1923, she pursued all her activities normally without unusual fatigue and the weight increased from 105 to 118 pounds (47.6 to 53.5 Kg.). From Nov. 15, 1934 to Jan. 15, 1935 she received no further treatment without recurrence of symptoms. During the entire period of treatment she has eaten her usual mixed diet and has not taken any ephedrine or aminoacetic acid or been permitted to eat any gelatin preparations.

CASE 2—A man, aged 50 while walking to the office July 8, 1933 experienced a sudden weakness of the legs and he fell to the ground. Eversion of any kind produced markedly abnormal weakness and he was obliged to remain in bed. Double vision, ptosis of the right eyelid, weakness of the jaw, difficulty in swallowing and weakness of the voice developed. At times the muscles cramped and pained him severely. Difficult breathing occurred on some occasions. There was a weight

loss from 149 to 105 pounds (67.6 to 47.6 Kg.) and he was confined to bed on a number of occasions for long periods. On one occasion for five months he was so helpless that he had to be turned in bed. There were several remissions, but for two months previous to the present examination he had been getting progressively worse and he was confined to bed almost continuously. Ephedrine had been given previously with slight transitory benefit, aminoacetic acid had not been used.

On examination he appeared poorly nourished and excessively fatigued. The face was expressionless, the eyelids drooped slightly and the movements of the eyeball were slow and absent at times. The reflexes were normal. The urine appeared normal, the blood Wassermann reaction was negative and the hemoglobin estimation was 80 per cent.

The patient was hospitalized and placed on a 2,000 calorie balanced diet. Aug. 20, 1934, daily subcutaneous injections of 1 cc of anterior pituitary extract were started. After the second day all pain and discomfort had disappeared, after the fifth day he was able to be up out of bed for several hours at a time without marked fatigue and by the tenth day he was able to walk at least half a mile without undue fatigue. Treatments were then continued at intervals of from two to three days, after three weeks he was able to perform hard work daily in the employ of a railroad company without undue fatigue. He stated that he had never felt better in his life. From October 13 to 23 treatment was omitted and he worked in the cold and rain on several occasions for sixteen hours at a time, all symptoms returned and he was again confined to bed. After resumption of treatment improvement again resulted. During cold weather it was necessary to continue the injections at daily intervals and on occasions two injections were given each day. No untoward effects have been noted from the injections at any time, no other treatment was given. Jan. 15, 1935, he was doing full time work. An attack of influenza in December, 1934, confined him to bed for about one week, but he convalesced from this without unusual difficulty.

SUMMARY

This report of the effect of subcutaneous injections of anterior pituitary extract in the treatment of myasthenia gravis is a preliminary study. The number of cases available is too small and the period of time over which they have been observed is too short to permit general conclusions, but the results so far are very encouraging. Both of these patients presented undoubted clinical evidence of myasthenia gravis. In both instances the response to treatment with anterior pituitary extract was prompt and complete, and a relapse promptly followed when the injections were omitted. On the resumption of treatment the symptoms again promptly disappeared in both cases. Since no other treatment was employed it would seem justifiable to conclude that this preparation had a marked beneficial effect on all the clinical manifestations of myasthenia gravis in these two cases.

In case 1 it was possible to discontinue the treatment after four and one-half months without recurrence of symptoms. It is impossible to determine whether this was the result of the fortuitous occurrence of a remission or whether a remission was induced by the treatment. In the second case it has been necessary to continue the treatment and during cold weather to increase the frequency of the injections in order to keep the patient clinically well. Whether a remission will be induced or not remains to be seen. In no instance have any untoward effects, either local or general, been observed as a result of the injections.

The oral administration of the extract would be preferable to its hypodermic use if it should prove as efficient. It is planned to try the relative merits of the two methods of administration.

1131 North Twenty-Eighth Street

⁶ The preparation used was an acid aqueous extract of the anterior lobe of the pituitary (Antuitrin) prepared by Parke Davis & Co.

ANORECTAL TUBERCULOSIS

A J CHISHOLM, MD
AND
HARRY GAUSS, MD
DENVER

By anorectal tuberculosis is understood a chronic inflammatory process of the terminal region of the bowel, caused by the tubercle bacillus, occurring commonly as a secondary involvement in pulmonary tuberculosis. It is characterized pathologically by swelling, induration, caseation, abscess, sinus and fistula formation, and clinically by a variety of symptoms including itching, sense of irritation, localized pain, painful defecation and the presence of a purulent discharge.

The literature on anorectal tuberculosis, or tuberculous fistula in ano as it is commonly called, is large and voluminous. Up to a few years ago considerable thought was given to the question whether or not all anorectal fistulas were tuberculous in character, and proponents of each view were easily found. Likewise, the questions of incidence, pathology, diagnosis and treatment have been the subject of many an acrimonious discussion. In addition to the modern literature, the ancient writings of Celsus, Hippocrates, the Old Testament, and even the Code of Hammurabi, probably the oldest known code of laws, contain references to fistula or related problems, so small wonder that the subject seems a bit bewildering at first glance.

It is our purpose in this paper to discuss our experiences with anorectal tuberculosis as we have encountered the problem in sanatorium and private practice in Denver. Our study is based on an analysis of seventy-one cases of proved or probable anorectal tuberculosis and 106 cases of nontuberculous supportive lesions of the terminal end of the bowel taken for comparative purposes.

INCIDENCE

The incidence of anorectal tuberculosis seems to be one of the disputed problems. In 1920 Thoss¹ reviewed the current German literature. He cited Richard Volkmann and Franz Koenig as believing that rectal fistulas were of tuberculous origin in the majority of cases, that de Quervain considered at least half of all rectal fistulas to be tuberculous, and that Melchior² found an incidence of 61 per cent at Breslau while Gös found rectal fistulas to be tuberculous in 45 per cent of cases at Munich. However, opposed to this view are the opinions of Lanz, who considers tuberculosis to be of little significance, and Frey, who found only 69 per cent of seventy-two surgical cases to be tuberculous by macroscopic and microscopic methods. Frey maintains that the criterion for the diagnosis is the nature of the pathologic alterations at the site of the lesion, while tuberculosis elsewhere in the body does not constitute sufficient evidence to justify the diagnosis. Melchior, however, contends that even negative microscopic examinations do not exclude the presence of tuberculosis in the fistulous tract. Thoss concludes that the reported incidence of from 50 to 60 per cent is entirely too high.

Martin³ states that 7 per cent of the patients at the Chicago Municipal Sanitarium have anal fistula.

Lockhart-Mummery⁴ states that 4 per cent of the tuberculous patients admitted to the Brompton Hospital were suffering from fistulas. Rickmann⁵ found that 26 per cent of the patients in a German private sanatorium had fistula in ano, and he believed that the percentage was higher in sanatoriums for the poor. Lawrason Brown⁶ states that fistula is a rather frequent complication of pulmonary tuberculosis, occurring in about 3 per cent of all cases.

In 1926 Clarke⁷ of Belfast reported his observations in 109 cases of fistula occurring in persons with pulmonary tuberculosis and observed that about 5 per cent of male patients have at some time ischiorectal abscess or chronic fistula, that about 5 per cent of fistula in ano can be proved tuberculous by histologic methods, while 20 per cent can be proved tuberculous by inoculation methods, further, that it is not always possible to distinguish by inspection the difference between a tuberculous and a nontuberculous fistulous tract, and that fistula in ano is thirteen times commoner in tuberculous patients than in nontuberculous patients.

In 1926 Leslie⁸ reviewed the literature and concluded that there was no uniformity of opinion regarding the incidence of tuberculosis of the terminal end of the bowel, he suggested that the following criteria be used to determine the pathologic nature of fistulous tracts: (a) guinea-pig inoculation of material from all specimens, (b) a histologic study of sections from all cases, (c) a comparative study, following definite diagnosis, of the history of all cases treated, and (d) more complete examination for tuberculous foci elsewhere in the body.

In 1925 Fansler⁹ stated that the diagnosis of tuberculous fistula is not justified except by definite microscopic picture or in cases in which the lesion has a typical appearance, further considering all cases of fistula in ano, it is doubtful whether more than 2 or 3 per cent are tuberculous in character.

In 1921 Gabriel¹⁰ made a detailed bacteriologic and histologic study to determine the percentage of rectal fistulas that are tuberculous, the required proof being the definite demonstration of the tubercle bacillus. The material examined was taken from seventy-five unselected cases coming to operation at the St. Marks Hospital. In thirty of seventy-five cases, guinea-pigs were inoculated. Pus, scrapings and granulation tissue taken from the lesions were properly prepared and inoculated into guinea-pigs. Histologic study was made on the tissues removed from all seventy-five patients. Of the thirty cases studied by guinea-pig inoculation six, or 20 per cent, proved positive for tuberculosis. Of these six patients, five were males. In age they ranged from 21 to 62 years. In the twenty-four cases that were negative by the guinea-pig test, only one pre-

sented evidence of pulmonary tuberculosis, while in two cases giant cells were found on microscopic section. In the forty-five cases examined by histologic methods only, tubercle bacilli were found in the stained sections of four cases (9 per cent), and these also revealed characteristic giant cells. Of these four cases, two showed evidence of pulmonary tuberculosis and two presented no evidence of pulmonary tuberculosis. Nine others showed giant cells but no tubercle bacilli, while the remaining thirty-two presented no suggestion of tuberculosis.

In 1933 a more detailed study was made in which the pus, scrapings and tissue removed from fistula in ano at operation were examined, every precaution being used to avoid extraneous contamination.¹¹ Only standardized histologic and bacteriologic methods were employed, and precautions were taken to obtain accurate clinical records regarding the tuberculous status of the patient. The guinea-pigs used were specially raised and safeguarded against spontaneous tuberculosis infection. The culture methods employed were those described by Corper and Uyei.¹²

A total of 155 cases were studied. 106 were clinically and roentgenologically negative for tuberculosis, eighteen presented evidence of arrested pulmonary tuberculosis, in thirty-one presenting active tuberculosis, tubercle bacilli were isolated in the specimens from twenty-four patients by the guinea-pig and culture methods, while one case showed tubercle formation or giant cells, another specimen showed granulation tissue reaction, while in none were tubercle bacilli found by any of the simple staining methods. Of the eighteen cases of inactive tuberculosis there were ten specimens in which tubercle bacilli were found by the guinea-pig or culture methods, and only three of these showed tubercle formation or giant cells. Of the 106 cases in which the patients were clinically free from tuberculosis, tubercle bacilli were not found by any of the methods.

These experiments lead to the observation that it is futile to place too much reliance on histologic methods alone, that the guinea-pig and culture method such as described by Corper are far more reliable tests, and that ischiorectal abscess and rectal fistula in persons clinically free from tuberculosis are seldom tuberculous, since tubercle bacilli were not isolated in any of the 106 patients who were clinically free from tuberculosis. On the other hand, when the patient has clinical tuberculosis either active or quiescent, the process is very likely to be tuberculous, since 77 per cent of these patients with active tuberculosis and 55 per cent of those with inactive tuberculosis were positive for tubercle bacilli.

The conclusion reached from a study of the literature and of the foregoing experiments regarding the incidence of anorectal tuberculosis is that from 3 to 5 per cent of all persons with pulmonary tuberculosis develop anorectal complications at one time or another and that these are generally tuberculous in character, whereas, similar lesions in persons who are clinically free from tuberculosis are likely to be nontuberculous in character.

AGE AND SEX

Powell and Hartley¹³ say that rectal fistula is almost entirely confined to males. Melchior found 92 per cent in males in a study of 192 cases of fistula. Von Kozuchowski found that 87 per cent of his 203 patients were males. Clarke found that ischiorectal abscess and fistula occur in males about eight times more commonly than in females. Our series of seventy-one patients with anorectal tuberculosis shows fifty-three males and eighteen females, a ratio of 3 to 1.

All ages are involved. Gabriel reports an age incidence of from 21 to 62 years. Our series shows the ages to range from 16 to 52 years. Since anorectal tuberculosis is a complication of pulmonary tuberculosis, the age incidence will follow the general age incidence of tuberculosis, as shown in the accompanying table.

PATHOLOGY

Anorectal tuberculosis generally occurs as a complication to pulmonary tuberculosis. It rarely occurs as a primary lesion. Fansler emphatically states that tuberculosis is but rarely primary in fistula in ano and that, if it occurs at all, the incidence is not more than a small fraction of 1 per cent. This view is entirely consistent with our own observations. In the examination of specimens removed at operation from 106 patients with ischiorectal abscess or fistula who were clinically free from pulmonary tuberculosis, tubercle bacilli were not

Age Incidence of Anorectal Tuberculosis Analysis of Seventy One Cases

Age	Number of Cases
16-20 years	4
21-30 years	30
31-40 years	24
41-50 years	12
51-60 years	1

demonstrated in a single specimen by the guinea-pig test or culture method, and histologic section showed giant cells in only two instances. It has been repeatedly argued that giant cells are suggestive but not pathognomonic of tuberculosis. On the other hand, in 77 per cent of thirty-one active cases of pulmonary tuberculosis and in 55 per cent of eighteen arrested cases the tubercle bacilli were recovered from the rectal lesions. It is quite likely that the actual incidence of anorectal tuberculosis was even higher than these figures indicate, since even the guinea-pig requires a minimum dose of from ten to 100 bacilli of a virulent strain to produce infection. Fansler¹⁴ states that in tuberculous patients more than 90 per cent of perirectal abscesses and fistulas can be proved tuberculous by laboratory methods.

Anorectal tuberculosis probably begins as an infection of a crypt at the junction of the skin and mucosa. When an infection has set in, certain forces operate to favor the spread of the inflammatory process. The first of these forces is the normal physiologic activity of the rectum and anus, wherein the periodic contractions and dilatations due to the passage of gases and fecal material prevent the infected parts from resting or adhering to one another. The second factor is the constant contact of the lesion with bacteria and fecal matter, which tends to maintain the septic process and favors reinoculation and secondary infection.

14 Fansler W. A. Rectal Care of the Tuberculous. Am. Med. 77: 8: 1931.

Once a tuberculous infection has set in at the anorectal region, there is a strong probability of the process spreading and giving rise to infiltration, caseation, abscess, sinus and fistula formation.

Regarding the gross appearance of the lesion, we do not believe that the gross pathology is diagnostic of tuberculosis. Of course it would be absurd to say that any tuberculous process does not produce characteristic changes but a study of the literature certainly indicates that there is no agreement as to what these gross evidences are. If there is any group or school that has a strong heritage of anatomic pathology, it is the disciples of Virchow. There are numerous German writers, such as Volkmann, Koenig, Melchior and Gös, who regard the majority of all rectal fistulas as being tuberculous in character, yet they are not supported by experimental studies which have shown that the majority of all rectal fistulas are definitely not tuberculous whereas it is only in those patients who have pulmonary tuberculosis that the rectal lesion is apt to be tuberculous. So the description of the gross appearance of the lesion must be left for further study.

In the past, most of the emphasis of anorectal tuberculosis has been paid to the fistula stage of the disease. One even finds efforts to drag the term "fistula" into the clinical picture. References to "closed fistula" are abundant in the literature, whereas the term is a contradiction, since there is no such thing as a closed fistula; the lesion rather is a "sinus." Between fistula and ischiorectal abscess there seems to be a literary gap, when actually all fistulas are terminal stages of abscesses. From a therapeutic point of view there is little difference between sinus, abscess and fistula. The indications and procedure of treatment is about the same in all.

Nevertheless, anorectal tuberculosis begins with a tubercle, a productive inflammatory reaction consisting of monocytes, lymphocytes, epithelioid cells and giant cells. The lesion begins in a crypt, which also harbors other pathogenic organisms, hence secondary infection takes place early. Induration, caseation and necrosis follow, giving rise to the anorectal abscess. Once formed, the abscess continues to enlarge and the pus burrows in the direction of least resistance. It may invade the ischiorectal fossa, producing an ischiorectal abscess, or it may burrow through the skin or mucosa forming a sinus, which becomes internal or external depending on its location, or it may form an artificial communication between the mucosa and any other neighboring surface, producing a fistula, which in turn may assume any of several forms and becomes designated as simple, multiple, complex, horseshoe or by any other descriptive term used to indicate its shape, position, complexity or multiplicity, or it may communicate with any of the neighboring organs, such as the bladder or the vagina.

SYMPTOMS

The symptoms of anorectal tuberculosis are extremely variable and depend on the extent and character of the pathologic process. The symptoms may consist of nothing more than a rectal consciousness, or there may be present intense pain markedly aggravated by defecation. Obviously, in the early stages of the disease the symptoms will be mild or even absent. Then as induration develops there will be a sense of fullness, discomfort on defecation, or itching, and on examination a lump may be palpated. As the induration stage passes on to caseation and abscess formation, the symp-

toms become markedly aggravated. The rectal consciousness develops into a sensation of discomfort, which progresses into pain commonly of a throbbing character, which tends to localize in one segment of the anorectal region. Constitutional symptoms may appear as chills, fever, leukocytosis, headache, backache, lumbago, and loss of appetite. Defecation becomes painful, sometimes micturition also becomes painful accompanied by a tendency toward inhibition, and the patient may become toxic. On examination a soft, tender, red mass is evident. Sometimes the symptoms of the abscess stage are much milder. In untreated cases the abscess will probably rupture into some outlet surface, producing either a sinus or a fistula, depending on the number of openings. At this stage the acute symptoms tend to subside and are followed by more chronic and less violent manifestations. From the opening of the sinus or fistula, a seropurulent exudate is discharged. The symptoms are rectal discomfort, burning, itching, and sometimes pain on defecation. Examination shows an adventitious opening into the rectum, anus or skin into which a probe may be passed. Sometimes the opening is difficult to locate, sometimes it is raised, or indurated, reddened and surrounded by an irritated or even by an eroded area while sometimes there is present fibrous tissue about the opening indicating an attempt at repair. Manifestations of skin tuberculosis may be present as milium cutaneous tuberculosis, lupus vulgaris, or scrofuloderma. When the opening is located, the contour of the fistulous tract may be evaluated by injecting methylene blue or, still better, an opaque substance that casts a shadow on an x-ray plate, which may then be studied leisurely for proper evaluation.

Secondary colon symptoms are quite common. Elsewhere we pointed out that rectal diseases, such as cryptitis, proctitis, hemorrhoids, fissures, fistulas and abscesses, commonly result in increased irritability, and thus gives rise to spastic or irritable colon, which becomes manifested by spastic constipation in which the stools are unsatisfactory to the patient, infrequent, difficult to evacuate, and of small caliber. Many patients acquire the cathartic habit as a result of prolonged colon irritability. Abdominal consciousness is common, also abdominal distress and pain are likely to occur in those cases in which there is already a centering of interest in the abdomen. Gastric symptoms sometimes occur as epigastric distress, hyperacidity and pylorospasm, and the differential diagnosis between peptic ulcer and rectal disorder with secondary gastric symptoms is by no means always a simple procedure. Flatulence and gas distress are of common occurrence. Sometimes certain constitutional symptoms develop, such as chronic fatigue, chronic indigestion, underweight, nausea, vomiting, introspection, insomnia and mental depression.

DIAGNOSIS

In the diagnosis of anorectal tuberculosis we are governed by the guinea-pig and culture studies in which anorectal material such as pus, scrapings or tissue removed from 106 patients who were clinically free from pulmonary disease failed to yield the tubercle bacillus, whereas similar material from thirty-one active cases and eighteen cases of arrested pulmonary tuberculosis yielded the tubercle bacillus in 77 and 55 per cent of the cases, respectively, and it is our impression that the actual incidence in these cases was even higher. In the case of intestinal tuberculosis, we have already expressed the opinion that in adults we would hesitate

to diagnose anorectal tuberculosis in the absence of pulmonary disease. In advanced anorectal tuberculosis, in which there is appreciable excoriation, fibrosis or skin involvement, the signs are very suggestive, but in the early case we hesitate to diagnose anorectal tuberculosis in the absence of pulmonary disease.

As to the type of anorectal lesion, whether it is a fissure, an infected crypt, a hemorrhoid, an abscess or a fistula, the diagnosis is readily made from the signs and symptoms. The differential diagnosis between these lesions has been amply covered in numerous standard textbooks on proctology and need not be repeated here.

It does not follow that all rectal lesions in patients with pulmonary tuberculosis are also tuberculous in character. In the case of intestinal tuberculosis, we¹⁵ reported elsewhere a study of 125 patients who were residents in a tuberculosis sanatorium and who presented gastro-intestinal problems. In this series, intestinal tuberculosis was diagnosed in only twenty-nine cases, or 23 per cent of the series. The remainder, or 77 per cent of the cases, presented nontuberculous ailments. Likewise, there are undoubtedly numerous anorectal lesions in the tuberculous that are nontuberculous, but they are of the type that are less likely to become involved in a tuberculous process by reason of not presenting an easy portal of entry, such as hemorrhoids, polyps and other lesions of a noninflammatory character, or open lesions in the early stage of development. The reason that fissures, sinuses, fistulas and other open lesions tend to become tuberculous, even if they are not tuberculous in the beginning, is the constant passage of tubercle bacilli at their openings, which, of course, favors tuberculous infection if it has not already set in. Thus Nussel¹⁶ in 1923 showed that, in 120 patients who had pulmonary tuberculosis, tubercle bacilli were found in the feces of 110 patients, which he explained as being swallowed organisms. Certainly since tubercle bacilli occur in the intestinal contents of so high a percentage of patients it becomes evident that any open lesion readily favors inoculation with the tubercle bacillus, in addition to those already infected.

The diagnosis of anorectal tuberculosis is another phase of the subject that is a matter of controversy. Sweany¹⁷ states that the diagnosis of tuberculosis in fistula of the anus and rectum depends entirely on the histopathologic changes, because the gross, clinical and bacteriologic changes are indefinite or of no value. The histopathologic diagnosis, he states, depends on the time honored presence of tuberculous granulation tissue with Langhans' type of giant cell characteristic tubercle formation and necrotic center, fibroblastic capsule and monocyctic and lymphocytic infiltration, however, he admits that granulation tissue of any chronic nature may simulate tuberculosis, even to the presence of giant cell formation. Nevertheless he maintains that with careful study more than 75 per cent of fistulas in the tuberculous should be found to be tuberculous, and he believes that all of them but an insignificant minority are tuberculous in character.

Our own experience, interestingly enough, arrives at the same conclusion as that of Sweany but by different diagnostic methods. In our hands histologic methods have proved disappointing, whereas the cul-

ture methods of Corper and the guinea-pig test have given high results comparable to that found by Sweany.

The diagnostic conclusion that we have arrived at is that in nontuberculous persons open anorectal lesions such as sinus and fistula are rarely tuberculous in character, whereas in patients with pulmonary tuberculosis such lesions are nearly always tuberculous.

INDICATIONS FOR TREATMENT

Tuberculous sinus and fistula are notoriously chronic in character. This holds true of all forms, whether they are located in the cervical region, bones, chest, anorectal region or elsewhere. Metcalf¹⁸ has pointed out that, of all forms of tuberculosis, ulcerating and fistulous tracts are the most difficult and least favorable for treatment, further, secondary infection is usually present, and if a cicatrix starts to form before the source of the discharge has cleared up, it soon breaks down again, reestablishing the fistula. In all forms of tuberculous fistula or sinus, there are present at least two factors that promote chronicity, namely, the tuberculous infection, and, second, the superimposed secondary infection. In lesions of the anorectal region there are present in addition to these the periodic contractions and dilatations, which interfere with the opportunities of the infected parts for rest and recuperation. In tuberculous fistula of the anorectal region it is true that healing sometimes begins, as manifested by the presence of scar tissue, but it is seldom completed. The statement that tuberculous fistulas are notoriously chronic is especially true in the anorectal region.

The following indications are present for treatment. The symptoms of rectal discomfort, pain, swelling or discharge demand attention as much in the rectal region as they do elsewhere. Further, a person who is burdened with a general disease should have the burden mitigated to any extent that it is possible to do so. In the general management of tuberculosis, the program calls for long periods of rest. This has its advantages, but it also has its disadvantages, one of which is giving the patient excessive opportunity for introspection, self analysis and self pity. The presence of a rectal lesion gives the patient one more opportunity in this direction. Another indication for treatment is the casual relationship existing between rectal pathologic changes and spastic or irritable bowel. A pathologic condition of the rectum is a direct etiologic factor of irritable colon and irritable bowel can make a hypochondriac of any person who has time for self analysis combined with a tendency in that direction, and many sanatorium patients are candidates for this additional burden.

Another indication for the treatment is the menace of focal infection. The infected rectum can become a primary focus of infection for lesions elsewhere in the body. The role of infected teeth, tonsils and sinuses as sources of focal infection is well recognized, infections about the rectum as a primary focus of infection is slowly being established. It is no longer an unusual experience to have some systemic infection such as arthritis persist after the teeth, tonsils, sinuses, gall-bladder and other viscera have been removed and then yield to treatment on the clearing up of a rectal infection. It has been our experience that many tuberculous patients who had an arthritis as well as fistula improved markedly after fistulectomy, as far as the arthritis was concerned in addition to some improvement in the pulmonary lesion.

TREATMENT

Treatment can be divided into three classes (a) therapeutic nihilism, (b) medical management and (c) surgical therapy

Therapeutic nihilism, a relic of a past age, is still extant today. There still remain therapeutic nihilists in existence. One encounters them here and there. The therapeutic nihilist has faith in nothing, sees no virtue in any procedure, does nothing, lets nature take its course and follows the path of least resistance.

Medical management consists of the general care of the tuberculous and secondly, local treatment of the lesion. Local treatment consists of various types of applications, injections, instillations and irrigations. Local therapy can be disposed of by simply stating that it is not effective. The general care for the tuberculous has its place in the therapy.

The third class is surgical therapy. Up to a few years ago surgical treatment was strongly condemned. It was generally considered merely a procedure for substituting one fistula for another. In 1926 Clarke wrote "Pulmonary tuberculosis should be rigorously excluded in every case of fistula before surgical treatment is considered." In 1927 we undertook to ascertain the existing attitude of internists in Colorado toward surgical treatment of anorectal tuberculosis. Questionnaires were sent to twenty-eight physicians who had had experience in the treatment of tuberculosis in sanatorium or private practice. Out of the twenty-eight replies only two favored the operation, four approved of it in selected cases and twenty-two opposed it.

In the light of existing experience with the knife operation performed under general anesthesia, this adverse reaction was justified. Too often the operation accomplished only an extension of the tuberculous process rather than a cure. The failure of operated lesions to heal after the knife operation probably resulted from an extension of the tuberculous infection along new channels that were opened up by the incision. The operation simply opened up new channels for the tubercle bacillus to infect, and, like similar lesions in the neck, chest, bones or elsewhere, the clinical results were unsatisfactory. Furthermore, the general anesthetic was regarded as having a deleterious effect on the pulmonary lesions.

However, important progress was made when the cautery was introduced and sacral anesthesia was substituted for the general inhalation anesthesia. Wood¹⁹ showed experimentally that in treating localized tuberculosis with the cautery there is a rewarding influence on the tuberculous infection, both in the immediate area and in the area adjacent to the operated tissue. The tissue treated with direct heat seems to be stimulated to fibrous tissue formation, which is a desirable result, also the use of the cautery seems to induce a type of inflammation that results in the formation of new blood vessels, which aids in the nutrition of the local tissues. Cauterization seals the lymphatics and blood vessels, thereby preventing a spread of the disease either locally through the lymphatics or generally through the blood vessels.

In the surgical treatment of anorectal tuberculosis, the matter of anesthesia occupies an important place in the therapy. The inhalation method of general anesthesia was found objectionable because of its deleterious effects on the pulmonary lesion. Too often

an aggravation of the pulmonary tuberculosis was noted after a general anesthesia. In the caudal anesthesia administered sacally, the objections to the general anesthesia are eliminated, yet complete anesthesia is obtained in the rectum, anus, perineum and buttocks, with complete relaxation of the sphincter muscles.

RESULTS OF SURGICAL TREATMENT

Within the past few years one of us (A. J. C.) employing the cautery and sacral anesthesia has operated on seventy-one tuberculous patients presenting various types of anorectal lesions such as abscess, sinus and fistula. Of these seventy-one patients fifty-one had active tuberculosis, while twenty had arrested tuberculosis. In one case only the clinical results after operation were unsatisfactory. In seventy cases, or 98 per cent the clinical results were very gratifying. Beyond a temporary discomfort and a slight increase in the pulse and temperature in some cases, the patients showed a marked improvement. Healing generally took place in from six weeks to three months. There was no spread of the tuberculous process at the rectum. There have been no recurrences in any of the patients, some of whom have been under observation for more than five years. Most of the patients made a slight gain in weight following the operation, and they showed a general improvement. In a few of the patients who had had some evidence of focal infection such as arthritis and rheumatism the improvement in these syndromes was most gratifying due to the removal of the foci of infection.

SUMMARY

1 This study is based on seventy-one cases of proved or probable instances of anorectal tuberculosis and 106 cases of nontuberculous suppurative lesions of the terminal end of the bowel, taken for comparative purposes.

2 In from 3 to 5 per cent of patients with pulmonary tuberculosis anorectal complications develop and these are generally tuberculous in character.

3 The age incidence of the patients with anorectal tuberculosis follows the general age incidence of tuberculosis.

4 Anorectal tuberculosis generally occurs as a complication of pulmonary tuberculosis. Primary anorectal tuberculosis is extremely rare.

5 The symptoms are variable and depend on the extent and character of the lesion. There may be present itching, irritation, localized pain, painful defecation, purulent discharge, induration, abscess, sinus, fistula or cutaneous tuberculosis.

6 In the diagnosis of anorectal tuberculosis, we have found that the injection of emulsions prepared from pus, scrapings or tissue injected into guinea-pigs or inoculated into suitable culture mediums is the most reliable test.

7 Experimentally we have found that such material from thirty-one active cases and eighteen arrested cases of pulmonary tuberculosis yielded the tubercle bacillus in 77 and 55 per cent of the cases, respectively. It is our opinion however, that the vast majority, over 90 per cent, of open suppurative lesions of the rectum in patients with pulmonary tuberculosis are or become tuberculous in character, this figure agrees with the opinions of Fansler and Sweany.

8 Treatment can be divided into (a) therapeutic nihilism, (b) medical management and (c) surgical care.

¹⁹ Wood G. B. The Use of the Electric Cautery in Laryngeal Tuberculosis. *Am J M Sc* 103: 854 (June) 1922.

9 Therapeutic nihilism and medical management of the anorectal lesions in the tuberculous are impotent in removing either the lesions or the symptoms arising from them

10 Surgical treatment employing the cautery and sacral anesthesia eliminates the older objections that were raised against the deleterious effects of the general anesthetic on the pulmonary lesion, and the dissemination of the local tuberculosis by the openings of new channels for further infection by the tubercle bacillus

11 One of us (A J C) has operated on seventy-one patients with proved and probable anorectal tuberculosis, including sinus, abscess and fistula. In seventy patients the clinical results were most gratifying. There occurred a complete healing of the local wound in from six to twelve weeks, there resulted in most patients a slight gain in weight, some improvement systemically, complete relief from the anorectal symptoms and in the case of those with manifestations of focal infection, a marked improvement from these syndromes

GOUT

CHANGES IN SYMPTOMS AND PURINE METABOLISM PRODUCED BY HIGH FAT DIETS IN FOUR GOUTY PATIENTS

L MAXWELL LOCKIE, MD

AND

ROGER S HUBBARD, PHD

BUFFALO

It has been known for many years that there is some relationship between gout and uric acid, and many investigations of the uric acid metabolism of gouty patients have been carried out¹. Because the number of cases of gout reported throughout the country is increasing, such studies are of especial interest at the present time. Some of the recent studies have shown that the methods of diagnosing the disease are apparently not wholly satisfactory, for in 100 cases an average period of fifteen years elapsed between the first appearance of symptoms and the establishment of the correct diagnosis². The differentiation of gout from chronic arthritis, when joints other than the big toes are involved, seems to be particularly difficult. We feel that the experiments reported here may serve as a basis of a useful test in helping to establish a correct diagnosis.

A number of workers have found that there is an increase in the blood uric acid and a decrease in the amount of that compound in the urine when normal subjects fast or ingest diets high in fat. In 1924, as the result of long and careful study, Lennox described such observations during twenty-two fasting periods, each at least eight days long, in two normal subjects and twenty-two patients with epilepsy³. When diets

high in fat were fed at the end of these fasts, no changes in the blood uric acid were observed, but when diets high in protein or carbohydrate were used there was a prompt return to the prestarvation level in the blood within twenty-four or forty-eight hours. As the blood uric acid fell, there was an increase in the amount of uric acid in the urine. Hoeffel and Moriarty⁴ in 1924 noted an increase in the blood uric acid of two fasting children. Harding and his co-workers⁵ in 1925 produced a marked increase in the blood uric acid concentration by giving high fat diets to women in the various stages of pregnancy. In these experiments a prompt return to normal values occurred as soon as high carbohydrate or high protein diets were fed.

It seemed logical to determine the effect of similar diets in gout, and therefore diets high in fat were fed to four gouty patients who came under our observation. The studies were carried out in the first medical service of the Buffalo General Hospital. To Dr Nelson G Russell, the attending physician, we are indebted for advice and encouragement extended during the experiments. The diagnoses were made according to the criteria of Hench². The details of the diets were arranged by the dietitians of the hospital, based on McLester's⁶ tables. The purine content of each diet was approximately equivalent to 0.042 Gm of uric acid daily, and the other constituents were varied to suit the needs of the individual patients and the experimental conditions that we wished to produce. The urinary uric acid was determined by the method of Benedict and Franke⁷ and the blood uric acid by Folin's direct uric acid method⁸.

Much to our surprise, striking changes in symptoms occurred when these diets were ingested. These clinical changes, which formed the most interesting part of the study, are described in the protocols of the separate experiments.

CASE 1⁰—History.—E H, a man, aged 52, admitted to the hospital in July 1930, complained of persistent headaches. During his stay he had an attack of gout in the left knee, characterized by increased warmth, pain and swelling, which lasted for about one week. Further questioning at this time revealed the fact that he had had periodic attacks of gout during the preceding eighteen years and that each of these incapacitated him for a period of from one to two weeks. During the intervals between the attacks he was completely free from joint symptoms. The joints most frequently involved were those of the knee and big toe. On two occasions tophi containing sodium urate crystals had been removed from the lobe of the right ear. In July 1932 many of the joints of the body were involved. There was marked swelling of the joints of the hands and feet. Both knees were swollen, warm and painful. It was necessary to give large doses of salicylates and opiates to control the pain. Small doses of colchicum did not help, large doses had not been tried.

Physical Examination.—The patient was well nourished and well developed. The afternoon temperature was 101 F and the pulse 110 per minute. He appeared to be suffering intense pain. The pharynx was reddened and a few cervical lymph nodes were enlarged. No rales were heard in the lungs, and

⁹ A preliminary report of the results obtained on this patient was given in the Proceedings of the Buffalo Academy of Medicine (Lockie, L. M. and Hubbard, R. S. Presentation of a Case of Gout. Bull. M. Soc. County of Erie and Buffalo Acad. Med. 11: 10 [Feb.] 1934).

the breath sounds were not changed. The left border of the heart was 11 cm from the midsternal line in the sixth interspace. The aortic second sound was accentuated. No murmurs were heard. The blood pressure was 175 mm of mercury systolic and 100 mm diastolic. The liver was not tender but the edge was palpable. No masses were felt in the abdomen. The hands, wrists, knees and ankles were swollen, warm, tender on pressure, and very painful on motion.

The urine was cloudy, with a specific gravity ranging from 1.010 to 1.020. The albumin content was 2 plus. The sediment contained from 30 to 40 white blood cells per high power field. The phenolsulphonphthalein excretion was 40 per cent in two hours. There was 80 per cent of hemoglobin present (Tallqvist). The red cell count was 4,800,000 and the white count 9,300 with 63 per cent polymorphonuclear leukocyte cells. The blood Wassermann reaction was negative. The blood uric acid was 6, the urea nitrogen 14, and the dextrose 130 mg per hundred cubic centimeters.

On roentgen examination the distal ends of the first phalangeal joints of the great toes had a punched out appearance that suggested gout.

Course—At a time when the patient had been practically free from symptoms for two weeks he was put on a high fat diet consisting of 50 Gm of carbohydrate, 50 Gm of protein and 220 Gm of fat. When he had been on this diet seven days, pain, swelling and tenderness in the joints of the feet and ankles developed. During this period the blood uric acid increased. The initial value was 5.5 mg per hundred cubic centimeters, and after eleven days on the diet it reached 8 mg per hundred cubic centimeters. There was also during this period a diminution of the amount of uric acid in the urine.¹⁰ No medication of any kind was given but the diet was changed to one consisting of 380 Gm of carbohydrate, 60 Gm of protein and 130 Gm of fat. Within two days a marked improvement in the symptoms took place. The carbohydrate was then reduced to 200 Gm because the patient could not eat the larger amount. Pain did not return, but the blood uric acid remained high for fourteen days. After that period of time 250 Gm of liver was fed. This did not cause an exacerbation of symptoms or a significant further increase in the blood uric acid. The blood uric acid remained high (between 7.2 and 7.8 mg per hundred cubic centimeters) for the next eleven days. Five days later, just before the patient left the hospital it fell to 5.7 mg; the value found before the dietary experiments were begun. Throughout this twenty-five day period the basal diet was 200 Gm of carbohydrate, 60 Gm of protein and 130 Gm of fat.

The patient has been seen every two or three weeks in the outpatient department up to the present time (October 1934). He has had a few twinges of pain in the small joints of the hands and feet, which have lasted for two or three hours at a time. His general health has been good.

CASE 2—History—W. R., a man, seen for the first time in February 1934, had been well until January 1930, at which time he had an excruciating pain in the left ankle. This disappeared in a few days, but shortly afterward the right knee became swollen and very painful. A diagnosis of rheumatism was made in another hospital, and the tonsils were removed one month later.

Each year after that time he had several attacks, presumably of gout, which involved the weight-bearing joints. One of these in 1932 also involved the small joints of the hands. He found that strenuous exercise, an alcoholic debauch or thorough chilling provoked attacks. Each episode followed the same course. There was marked swelling, pain, tenderness and limitation of motion. Within from ten to fourteen days there was complete recovery from joint symptoms.

¹⁰ Marked temporary fluctuations in the rate of excretion of uric acid are common in gouty patients (His, W. Die Ausscheidung von Harnsäure im Urin der Gichtkranken mit besonderer Berücksichtigung der Anfallszeiten und bestimmter Behandlungsmethoden. Deutsches Arch. f. klin. Med. 65: 156, 1900) and were found during our experiments. These made interpretation of the urine changes difficult, for it was necessary to follow the general trend of changes in values and to ignore occasional large variations in them. The interpretation was further complicated by failure to collect accurate twenty-four hour specimens in all instances. To minimize the effect of such failures the creatinine content of each urine was determined, the ratio between creatinine and uric acid calculated and variations in the values of this ratio studied.

Albuminuria was found in 1926. A molar tooth was extracted and an incision washed in 1933 without producing a flare up of symptoms.

Physical Examination—The patient was fairly well nourished. The temperature was 99.6 F. No tophus was found. The heart was slightly enlarged. No heart murmurs were heard. The blood pressure was 130 systolic and 80 diastolic. Several joints were involved. Those showing the most pronounced symptoms were the left knee and ankle. There was marked swelling, tenderness and limitation of motion. No urethral discharge was present.

Analyses of the urine showed that the specific gravity varied between 1.013 and 1.020 and that it contained 3 plus albumin and a few hyaline casts. The hemoglobin was 68 per cent (Sahli). The red blood cells numbered 4,400,000 and the white cells 14,000 with 75 per cent polymorphonuclear cells. The blood sedimentation rate was greatly increased. The uric acid concentration was 6.2, the urea nitrogen 35, the nonprotein nitrogen 71 and the creatinine 2 mg per hundred cubic centimeters of blood.

Course—He recovered from the joint symptoms in a few days and stated that, judging from past experience, he would not have another attack for some months. After one week he consented to ingest a diet containing 60 Gm of carbohydrate, 60 Gm of protein and 230 Gm of fat. Within three days he felt poorly. The left hand and knee were swollen and painful. The joints in the left hand were especially sore. He felt so ill that he stayed in bed although previously he had been ambulatory for five days. No medication of any kind was given and the diet was changed to one consisting of 400 Gm of carbohydrate, 70 Gm of protein and 60 Gm of fat. There was marked improvement in the symptoms within forty-eight hours. No significant variations in the blood uric acid were found at any time during the experiment. In three determinations on different days the values lay between 5.5 and 5.8 mg per hundred cubic centimeters of blood. The explanation of this constancy of the blood uric acid seems obvious. The diet high in fat was taken for only three days, and demonstrable changes probably should not have been expected.

During the five months that have elapsed since the experiment there has been no recurrence of joint symptoms.

CASE 3—History—A. A., a white man aged 74, Jewish, admitted to the first medical service in October 1933, during the preceding twenty-three years had had at least twelve attacks of gout. Each time there was pain, redness and swelling of the joints of the lower extremities, particularly of the big toe joints, the right knee and the right ankle. Between attacks he felt entirely well. Two weeks before he entered the hospital pain developed in the right foot. This was followed a day later by swelling of the subcutaneous tissue. During this period he felt poorly.

For ten years dyspnea on exercise and occasional edema of the ankles had been present. He had had nocturia for three or four years and had lost 30 pounds (13.6 Kg) during the two years preceding admission.

Physical Examination—He seemed well nourished. No tophus was seen. The area of precordial dulness was slightly enlarged. No murmurs were heard on auscultation of the heart. The blood pressure was 128 systolic and 90 diastolic. The liver edge was palpable. The right foot was warm and painful to touch and could be moved very little without causing great pain. No other joints were involved.

The specific gravity of the urine varied from 1.015 to 1.018 in various specimens, and 3 plus albumin was present. The hemoglobin was 78 per cent (Sahli) and the red cells numbered 4,200,000. There were 12,000 white cells, 75 per cent of these were polymorphonuclear cells. The blood Wassermann reaction was negative. The basal metabolic rate was minus 3 per cent. The concentration of uric acid was 6.8, of urea nitrogen 34 and of dextrose 130 mg per hundred cubic centimeters of blood.

On roentgen examination the feet showed a decreased density in the distal ends of the first metatarsal bones and two small areas that had a punched out appearance.

Course—The patient had entered the hospital at approximately the end of an attack of gout. After he had been without signs or symptoms for one week he predicted that, judging from past experience, he would not have another exacerbation for at least ten months. A diet of 20 Gm of carbohydrate, 30 Gm of protein and 300 Gm of fat was then given. Within forty-eight hours pain developed in the right foot. Shortly afterward the foot became swollen and tender. No medication was given, but the diet was changed to one consisting of 350 Gm of carbohydrate, 60 Gm of protein and 8 Gm of fat. Within seventy-two hours all the signs and symptoms had disappeared. After he had been free from pain for one week he agreed to take the high fat diet again. Within two days he noticed the same symptoms and signs that he had felt during the previous test. The diet was changed to 440 Gm of carbohydrate, 80 Gm of protein and 120 Gm of fat and the symptoms disappeared within three days. At no time during the experiment were significant changes in the blood uric acid found. Seven of eight determinations gave values between 6.5 and 7.0 mg per hundred cubic centimeters, and the eighth was only slightly lower than the others 5.8 mg. The lowest value was present on the second day of the second period on a high fat diet.

The patient left the hospital thirteen days after the last bout had subsided. He was seen two months later in the outpatient department and reported that he had been free from symptoms during the intervening period.

CASE 4—History—N. G., a white youth, aged 16 years, admitted to the first medical service Feb. 22, 1934, stated that in 1932, following a respiratory infection, hematuria, albuminuria, edema of the face and legs, and an increase in blood pressure had developed. It was noticed that tophi were present in the lobes of the ears at that time. The family physician advised the boy to be very moderate in exercising and to eat very little meat. He had rarely tasted liver and other internal organs. He had never used alcohol. During the latter part of December 1933 he suffered his first joint pains, which began in the right ankle. It was red, swollen and very painful. He could not allow the bedclothes to touch his foot. The attack lasted ten days and was followed by complete recovery. He was well for five weeks, and then the left wrist became swollen, tender and painful for one week. Following this there was no residual deformity or loss of function. He entered the hospital at the end of his third attack which had begun one month after the previous one. This time the left ankle and big toe joint were involved. There was some pain and tenderness with limitation of motion.

His father and four males on his father's side had died of kidney trouble. No family history of gout was obtained.

Physical Examination—He was well nourished and not acutely ill. Tophi were present in both pinnae. The pharynx was reddened. The heart sounds were regular, but the first sound at the mitral area was roughened, and the pulmonary second sound was greater than the aortic second sound. The blood pressure was 142 systolic and 100 diastolic. The left knee was red and swollen. It was warm and extremely painful when touched. There was no evidence that other joints were actively involved or that they had been affected by his previous bouts.

The specific gravity of the urine varied from 1.007 to 1.022 and no albumin or dextrose was found. The hemoglobin was 90 per cent (Sahli). The red blood cells numbered 4,250,000 and the white cells 9,050, with 67 per cent polymorphonuclear cells. The two hour urine concentration test showed a variation in specific gravity from 1.003 to 1.015. The night output of urine was about one third of the day output. The blood sedimentation rate was greatly increased when he was admitted and normal when he was discharged. The basal metabolic rate varied with therapy from minus 29 per cent to plus 3 per cent. No agglutinins for *Streptococcus haemolyticus* (A B 13) were found in the blood serum. The blood chemical examinations on admission revealed dextrose 143, calcium 11.9, inorganic phosphorus 4.4, cholesterol 153 and uric acid 7.6 mg per hundred cubic centimeters of blood.

On roentgen examination the left wrist and the feet did not reveal punched out areas or signs of decalcification. No renal or bladder calculi were seen.

Course—With few signs of the active attack remaining, he was placed on a diet of 225 Gm of carbohydrate, 60 Gm of protein and 70 Gm of fat. Sodium salicylate and colchicine were given for one day. He felt better for a few days, but then several joints became involved. After six days the symptoms disappeared and he felt very well. During this period he was taking 2 mg of colchicine daily.

After he had been clinically free from symptoms for one week the diet was changed to 50 Gm of carbohydrate, 50 Gm of protein and 250 Gm of fat. The colchicine, 2 mg daily, was continued during one week of this experimental period. The amount of fat was raised to 300 Gm, and six days later he had pain in the wrists and metacarpal joints. There was no swelling at this time. On the following day the pain increased and he felt poorly. The third day after the onset of the attack pain appeared in the right shoulder, and after another twenty-four hours there was swelling in the left wrist and hand. Then the joints of the right hand became involved, and within another day the joints of the left foot were sore. The pain persisted in all the joints that had already been affected. An injection of 50 cc of 50 per cent dextrose intravenously gave a little relief, but this lasted only for an hour. The pain now was almost unbearable when he touched the bed. The diet was changed to one consisting of 350 Gm of carbohydrate, 50 Gm of protein and 50 Gm of fat. Within two days he felt much better although no medication of any kind was given.

During the time he was on the high fat diet the concentration of uric acid in the blood increased from a value of 8.6 to one of 16.0 mg per hundred cubic centimeters, and there was a significant decrease in the rate at which uric acid was excreted in the urine.¹⁰ There was no drop in the level of uric acid in the blood during the first eight days when he was taking the high carbohydrate diet. Determinations on four occasions gave values between 13.5 and 15.0 mg per hundred cubic centimeters. Again it should be pointed out that the patient was free from symptoms during this period. Because of the persistent hyperuricacidemia, he was given sodium salicylate in doses of 2 Gm every two hours. The blood uric acid dropped to 10 mg per hundred cubic centimeters after this drug had been used for three days and eight days later, with continuation of the therapy, it reached 6.5 mg, a value slightly lower than the one found on admission.

Five days after the conclusion of the experiment just described, while the patient was still on a diet low in fat (50 Gm) and high in carbohydrate (350 Gm) there was a recurrence of symptoms that lasted for five days. At this time the basal metabolic rate was minus 29 per cent. Thyroid extract (Parke, Davis & Co.) was given in doses of 0.03 Gm three times a day to raise the basal metabolism and to aid in the excretion of uric acid. No other medication was used. During the remainder of his stay in the hospital he was free from symptoms except for occasional fleeting pains in the hands. Ingestion of 500 Gm of liver did not aggravate his condition. The diet was kept at 500 Gm of carbohydrate, 50 Gm of protein and 50 Gm of fat.

During three months of observation in the outpatient department, he has had only two or three days of mild pain.

COMMENT

The ingestion of high fat diets by these patients with gout resulted in certain metabolic and clinical changes that merit detailed discussion. The metabolic changes will be discussed first. Two of the patients took the diets high in fat for fairly long periods. In the blood of each of them the amount of uric acid at the end of the experiment was markedly higher than it had been at first. Patient 1 showed a uric acid concentration of 8 mg per hundred cubic centimeters after he had been on the diet for eight days. This value was 60 per cent higher than the one found when he first presented himself at the clinic. Patient 4 took the diet for eleven days. On the last day of the test, 16 mg of uric acid was present in each hundred cubic centimeters of his blood. This was double the concentration present at the beginning of the test. In two

other patients such extreme pain developed when they took the diet that it was necessary to discontinue the diet after three days. Neither of them showed any significant change in the blood uric acid. The results closely resemble those found in various investigations of persons not suffering from gout, high fat diets fed for a week or more regularly cause increases in the blood uric acid comparable to those observed in the experiments first described, while similar diets fed for shorter periods do not cause such changes. Patients with gout and normal subjects therefore show the same metabolic response to diets high in fat.

When, however, attention is centered on the rate at which the blood uric acid values decreased after the diets high in fat were replaced by those high in carbohydrate, a striking difference between patients with gout and those with other conditions is seen. In all previous articles dealing with such metabolic studies in nongouty subjects it has been stated that the blood uric acid returned promptly to normal when the high fat diets were discontinued. Neither of our subjects who ingested the diet for a long period showed a prompt change of this kind after the diet had been stopped. It was not until a diet high in carbohydrate had been fed to patient 1 for twenty-four days that the blood uric acid fell to the level present before the high fat diet was begun and such high values were still present eight days after the diet in case 4 had been changed that we felt it desirable to use salicylates to hasten the excretion of uric acid. It seems to us that there is some resemblance between this marked persistence of increased blood uric acid values after the ingestion of high fat diets and the delay in the excretion of uric acid after feeding diets rich in purines,¹¹ or after injecting uric acid,¹² which patients with gout regularly show. It seems probable that all three changes result from the same underlying cause.

The most interesting observations in this study were the changes in the clinical symptoms of the patients. There was an exacerbation of the signs and symptoms when these patients were fed diets high in fat, and in a majority of the experiments the attacks developed within a few days after the patients had been placed on the diet. It should be stated explicitly that these clinical changes were fairly independent of changes in the uric acid content of the blood, for (1) they were noticed in experiments that were too short in duration to cause variations in the blood uric acid, and (2) in two cases with marked increases in the blood uric acid the symptoms decreased or disappeared while the blood uric acid was still high. These changes in symptoms might have been due to changes in the amount of uric acid in the tissues around the joints, but no evidence is available to prove such a theory.

The regularity with which this clinical response was observed led us to investigate the relationship between the ingestion of a high fat diet and the occurrence of joint symptoms in other conditions. No mention of the development of such symptoms is contained in the physiologic papers to which reference has already been made. Wright and Hubbard,¹³ who fed diets high in fat to fifteen patients with chronic arthritis, did not encounter any noticeable exacerbation of the signs of

the disease.¹⁴ The results of a few experiments of our own were similar to those of the authors just mentioned. Four patients with chronic arthritis were fed diets high in fat for at least seven days, and there was no change in the clinical manifestations of the disease in any instance.

Since patients with gout appear regularly to experience an exacerbation of joint symptoms when they are fed diets high in fat and since other groups of patients do not do so, we propose the following test for differentiating gout from various forms of chronic arthritis. Feed a diet consisting of from 250 to 350 Gm of fat, 50 Gm of protein and from 30 to 50 Gm of carbohydrate for a period of from five to seven days. If within that time pain in the joints has developed, or if existing mild joint pains have markedly increased in severity, a diagnosis of gout must be carefully considered. The symptoms that may develop can be promptly relieved by feeding a diet high in carbohydrate and low in fat.

SUMMARY AND CONCLUSIONS

When diets high in fat and low in carbohydrate and protein were fed to patients with gout, the following effects were observed:

- 1 The concentration of uric acid in the blood increased and the amount excreted in the urine decreased if the diets were ingested for reasonably long periods. These results were approximately the same as those which have been found in the study of normal subjects.

- 2 When diets high in fat were withdrawn and replaced by diets low in fat and high in carbohydrate the blood uric acid returned very slowly to the initial level. This result differs from experience with normal subjects who under similar conditions show a prompt return of the uric acid in the blood to normal values.

- 3 Each time a patient was given a diet very high in fat, an attack of gout occurred within a few days. The joint symptoms subsided shortly after the patients were placed on a low fat-high carbohydrate diet.

- 4 These variations in the clinical symptoms were not directly dependent on changes in the uric acid concentration in the blood. Attacks were noted before increases in the blood uric acid occurred in some instances and disappeared while the blood uric acid was still high in others.

- 5 Similar diets did not cause exacerbations in the symptoms of patients suffering from chronic arthritis.

We feel justified in making the following recommendations as the result of these experiments:

- 1 The development or exacerbation of joint symptoms following the ingestion of a diet high in fat and low in carbohydrate and protein for several days may serve as a useful test in the differential diagnosis of gout.

- 2 Diets high in fat and low in carbohydrate should be avoided in the treatment of patients with gout.

THE QUESTION OF HOMOPLASTIC
SKIN GRAFTING

H M TRUSLER, MD

AND

H D COGSWELL, MD

INDIANAPOLIS

The homoplastic transplantation of skin, in other words, the transference of skin from one individual to another, is a procedure about which there is much controversy. The subject receives such apparently favorable publicity that most laymen and likewise many physicians assume that the homoplastic transplanting of skin is a successful procedure, another accomplishment of modern science. The fact is that practically all recent scientific observation has proved that the homoplastic skin graft is unsuccessful.

These rather disconcerting statements deserve an explanation which we hope to give after reviewing a few salient facts. Practically speaking, skin grafting of any type was first accepted as a surgical procedure in 1869 after Reverdin¹ had reported his success with "pinch grafts." Following this, the various types of split skin and whole thickness skin grafts were described by Ollier, Thiersch, Wolfe and Krause. Along with the numerous reports of success with autoplasmic transplants of skin, various efforts at homoplastic grafting were likewise reported.

Girdner² in 1881 reported a case in which skin was taken from a body six hours post mortem and placed on a granulating area on a boy aged 10 years. He reported that most of this graft sloughed because of infection. Bartens,³ however, in 1888 reported a similar case, which he stated was successful.

Gatch⁴ in 1911 reported the case of a Negro who received grafts from two donors. These homoplastic grafts all sloughed, while autoplasmic grafts were highly successful on the same patient.

With the advent of knowledge concerning blood groups and the success of blood transfusion, interest arose in the thought that blood compatibility might be a factor in homoplastic skin grafting. The transference of skin between individuals of the same blood group was termed iso-skin grafting, and Davis⁵ has given several reports of success with isodermal grafts. In accounting for the failure observed in many of his cases he was inclined to assign infection as the cause, although he observed that infection was much less frequent in his autoplasmic grafts. Neuhoef,⁶ Underwood,⁷ Hoguet,⁸ Masson⁹ and Shawan¹⁰ also expressed the view that satisfactory results in homoplastic skin grafting could be obtained when donor and recipient were in compatible blood groups.

Loeb,¹¹ however, considered it very improbable that the blood group of donor and host could be of any great significance. Blair and Brown,¹² who followed their cases very closely, stated that homoplastic grafts could be made to take but that in all cases after a few weeks the grafts sloughed away.

Faced by such conflicting reports, the average physician naturally has felt inclined to look on the homoplastic skin graft as a "noble experiment" worthy of trial when indicated. On several occasions we have faced a situation with relatives and friends eager to sacrifice small areas of skin to an unfortunate victim of a third degree burn. In most instances we have not accepted these offers, stating that the procedure probably would not be successful and might even be dangerous. Underwood⁷ and Holman¹³ both have reported what appeared to be serious allergic reactions following the application of isodermic grafts.

PERSONAL OBSERVATIONS

In five cases we have felt justified in attempting the homoplastic transplantation of skin. In brief, the results were as follows:

1 In most instances the grafts took, that is, they adhered and remained in place for a variable number of weeks. In no case, however, was a homoplastic graft permanently successful.

2 In one case a child was burned over such an extensive area that her survival for a period of approximately a month seemed miraculous. At that time a few small Thiersch grafts were taken from her mother, who was of the same blood group, and placed on the granulating surfaces of the child, together with several grafts cut from accessible areas of her own skin. The grafts took, homoplastic and autoplasmic alike, but after several days the child became toxic with chills and septic temperature and died.

3 The other four patients all survived and eventually the wounds healed, but certainly the healing could not be taken as proof of successful iso-grafting. We observed definitely that these grafts sloughed away, usually in a gradual fashion over a period of days or weeks, while autografts in adjacent areas remained viable. Furthermore, it was quite apparent that the ultimate healing by cicatrization was markedly delayed in the areas which had received the homoplastic grafts.

4 We can readily understand why infection might be assigned as the cause of failure in such grafts. It is common knowledge that infection and slough may complicate any skin grafting procedure, though with proper technique the autoplasmic skin graft is highly successful. In our experience the appearance of the gradually sloughing homoplastic graft is not unlike that of indolent infection, but infection probably is not the basic cause. More will be said of this.

5 In one instance a child presented extensive granulating areas three months following a burn on the back. Together with a few Thiersch grafts cut from her own skin, several similar grafts were transferred from the father, whose blood was compatible. All these grafts adhered completely and appeared to grow for six weeks, during which time the child's general condition remained good. The father's grafts then began slowly to melt away, while her own skin grafts remained

health. After two more weeks it was apparent that the grafts from the father were undergoing progressive necrosis, mere fragments of the basal layers remaining. At this time a different area of granulation tissue received Thiersch grafts from the mother, whose blood was not compatible, and also several small grafts from the child's own skin. None of the mother's grafts grew. At the end of two weeks those which had first shown a tendency to take were undergoing rapid necrosis. During this interval the child's temperature, which previously had been normal, became septic and toxic symptoms developed. Following this all granulations became unhealthy and healing progressed very slowly, even though the areas were given radical debridement to remove all remnants of the homoplastic grafts. With the aid of small Thiersch grafts from the remaining areas of her own available skin healing eventually was sufficient to permit release from the James Whitcomb Riley Hospital four months following the initial graft.

COMMENT

From our own experience and a critical survey of the literature we are led to believe that most reports of success with homo-skin grafts arise from the fact that these grafts can and often do adhere and appear to grow for several weeks. In our cases, however, such grafts have not remained viable their ultimate fate being a more or less delayed slough. Healing by cicatrization eventually occurs. These observations are in agreement with recent reports of others. Padgett,¹⁴ however, although in general his observations agree with ours, has reported successful growth in skin transplants between identical twins. The grafts in one such instance were healthy and growing after three months. Gilhes¹⁵ states that at the present time homolografting in general is successful when the transplants involve vascular tissues, notably cartilage and cornea. He admits that homografts of skin, as commonly transplanted are for all practical purposes unsuccessful. Certainly this is in accord with our experience. It does appear that blood compatibility may tend to favor the initial take of the graft. We have found, however, that ultimately these grafts not only are futile but are detrimental to healing or even dangerous to the life of the host.

It would seem that homotransplanting of tissues in man, for the most part, fails because of biologic incompatibility, the necrosis that occurs being due primarily to antagonism between the host and the foreign protein of the graft. The infection that may be observed is probably secondary and not the basic cause of the slough. We note with interest the report of Stone, Owings and Gey¹⁶ concerning the successful homoplastic transplantation of glandular tissue by a technic in which the donor's tissue is first transferred to culture in vitro with the recipient's serum as a medium. This work is as yet in the experimental stage, but the reports are encouraging.

The fact remains that, as commonly practiced, homolografting of skin is useless, deleterious and unnecessary. Massive destruction of skin is usually due to a burn, and the individual who survives such an injury will have sufficient intact surface to make healing possible with the aid of grafts from the patient's own skin.

In passing, we wish to emphasize the importance of early skin grafting in the management of such burns.

By this procedure much deformity, disfiguration and suffering will be prevented and lives will be saved. Many severe burns are seen unhealed and septic after many months. In the management of such cases we wish to emphasize the value of ultraviolet therapy as reported by Gatch and Trusler.¹⁷

We do not deny the obvious fact that in many cases the homoplastic grafting of skin would be a great help if a practical solution of the problem could be discovered.

THE TREATMENT OF VARICOSE VEINS

IS SYSTEMIC DISEASE A CONTRAINDICATION?

EDWARD A. EDWARDS, M.D.
BROOKLINE, MASS.

This paper is based on a study of 1,000 consecutive patients treated for varicose veins in the circulatory clinic of the Boston City Hospital from late in 1930 to the close of 1933. It includes many patients suffering from coexisting systemic diseases such as diabetes and syphilis, and diseases of the heart, lungs and kidneys. The study was undertaken to determine whether it is dangerous or unwise to treat such patients by the injection of sclerosing agents or by this injection plus the operation of ligation.

The literature is controversial on this subject. Of those taking a cautious attitude may be quoted de Takats,¹ Kilbourne,² Beckman³ and McKinstry.⁴ The conditions that they list as contraindications to treatment are old age, simple debility added to old age, nephritis, heart disease, hypertension, diabetes, tuberculosis, hyperthyroidism, severe focal infection, and the common cold. De Takats believes that the treatment may bring on angina in a patient who is subject to this disease. He has also seen a case of military tuberculosis which he infers was caused or precipitated by the injection.⁵ Kilbourne includes focal infection because of the danger of a metastatic phlebitis in the treated vein and for the same reason advises against injection immediately after the extraction of a tooth or during an acute cold or pharyngitis. A midway position is maintained by Forestier,⁶ O'Neil⁷ and Schussler.⁸ Forestier says: "Old persons with enfeebled health should not be given injections." A previous medical examination is necessary, particularly as to the condition of the heart, the function of the kidneys (albuminuria) and the possibility of diabetes." O'Neil

says "Every patient is (first) to be examined to determine whether there exists any contraindication to the treatment"

Genevri⁹, who introduced quinine and urethane as a sclerosing agent, makes no mention of any contraindication to its use McPheeters¹⁰ takes a positive and optimistic stand He has summed up his attitude as follows

Neither a high nor a low blood pressure is a contraindication per se If the patient has diabetes and bad varicose veins, he should be treated, but avoid the sugar solutions If the patient has nephritis, avoid any solution which is irritant to the kidney In cardiac conditions the patient's general condition is improved by the treatment of his varicose veins, but in no case should treatment be given when the patient is decompensated or bed-fast for any reason

The latter caution is to avoid the danger of embolism from a propagating stagnation thrombus, which may form if a patient goes to bed after the injection

THE STUDY¹¹

At the inception of the circulatory clinic of the Boston City Hospital in 1929, the rule was made that no patient was to be treated unless he was first examined by the medical department "to rule out any disease that might contraindicate treatment" However, the injection treatment was early shown to be quite innocuous through the efforts of Dr E E O Neil of the circulatory clinic It seemingly came about that the internists and the surgeons were equally puzzled as to what constituted a systemic contraindication to the

treatment of the varices It was therefore very soon that patients were treated whether or not they had other concomitant diseases like those previously mentioned The only condition that has remained a contraindication in the clinic is pregnancy, which condition I shall discuss later

The records of these 1000 treated patients are therefore rich in instances of coexisting systemic disease The patients were examined by either the house officers or the visiting physicians, and, since the house officers in the medical clinic change every three months and the visiting physicians every month there was a considerable number of men who handled these patients The thoroughness of the examinations varied all had at least their hearts and lungs examined

Almost every patient had the urine examined and the blood pressure taken But frequently the history was brief One may therefore presuppose that if these records are in error, they are more apt to leave out systemic disease when it existed than otherwise

The age of the patients at the time of first application for treatment was such as to make likely the frequent existence of conditions such as senility, arthritis, constipation, obesity, cholecystitis and, in the women, the menopause (chart 1) I feel that whether or not these diagnoses were placed in the record depended largely on the extent of the history, and the

Chart 2—One thousand consecutive patients with varicose veins Incidence of serious systemic disease

individuality of the examiner I therefore merely note that a great number of the patients suffered from these conditions

Considering the more serious diseases with more objective changes we found an incidence of 375, or 37.5 per cent of the 1,000 patients (chart 2) Of this number 219 patients were suffering from hypertension¹² There were 123 patients with some disease of the heart, many of whom had hypertension with arteriosclerotic and hypertensive heart disease, while others were merely diagnosed as having myocarditis, auricular fibrillation or cardiac hypertrophy There were but few cases diagnosed as angina pectoris, though heart pain was described in many of the histories of the patients with the other heart diseases There were only eight cases labeled nephritis, with many more probably implied in the hypertensive or arteriosclerotic heart patients An additional forty-four patients had albuminuria There were seventy cases of respiratory disease, including chronic bronchitis, bronchiectasis, emphysema and tuberculosis, and one case of pneumoconiosis There were four cases of extrapulmonary tuberculosis There were three cases of alcoholic cirrhosis of the liver Diabetes was diagnosed twelve times, syphilis fifteen times (The blood was examined for syphilis in only 149 patients) Diseases of the thyroid were diagnosed fourteen times and included toxic and nontoxic goiters colloid goiters and hypothyroidism Peptic ulcer was diagnosed five times There were only five patients diagnosed as suffering from malnutrition or anemia or both This figure is of course too low, as approximately from one third to one half of our patients are destitute and receive aid from the city welfare department For the same reason the stated presence of carious teeth and other foci of infection may be passed over as altogether too low, they are actually very frequent in our patients It is worthy of note that many of these patients were in middle or old age (chart 1)

As to the type of treatment and the substances used, every one of these 1,000 patients had received at least one injection of quinine and urethane, and, in some cases as many as ninety-five injections were given

Chart 1—One thousand consecutive patients with varicose veins Age in decades at which patients appeared for treatment.

the house officers in the medical clinic change every three months and the visiting physicians every month there was a considerable number of men who handled these patients The thoroughness of the examinations varied all had at least their hearts and lungs examined

11 I am indebted to Dr Cadis Phipps, professor of medicine at Tufts College Medical School director of the First and Third Medical Services and physician in chief Third Medical Service of the Boston City Hospital for advice concerning the medical problems involved

12 The criterion used was a systolic blood pressure above 145 mm of mercury In most of the patients diagnosed as hypertensive the blood pressure was tested several times

The solution used contained 0.091 Gm of quinine hydrochloride and 0.052 Gm of urethane in each cubic centimeter of water.¹³ The dose used by most of the surgeons was 0.5 cc at the first visit and 2 cc thereafter, although I have been using 5 cc of this solution as a routine dose for the past two years. In addition to the quinine urethane, we have used 5 per cent sodium morrhuate in some cases¹⁴ and less frequently sodium chloride (20 per cent) or sodium chloride (15 per cent) with dextrose (25 per cent) or varisol (invert sugar and sodium chloride). Also since early in 1932 we have used the ligation of the saphenous vein as a preliminary to the injections in some cases. This operation of ligation of the great saphenous vein was carried out seventy-five times in this series.¹⁵

In considering the possible systemic effect of the various sclerosing agents their pharmacology might perhaps be discussed briefly. In the combination of quinine and urethane, one has to consider the action only of the former, as urethane (ethyl carbamic ester) is too weak and inconstant in the dosage used to be of any possible danger, especially as it is easily oxidized to urea. Aside from the possible idiosyncrasy for quinine, I realize that large doses, given intravenously, may result in a fall in blood pressure and cardiac depression as well as in a depressing effect on the central nervous system but in the dosage used for the treatment of varicose veins (from 0.182 to 0.455 Gm) there is no reason to expect any general or systemic results, and apparently no definite ones have been reported. There seems no valid objection to the use of quinine in an individual suffering from nephritis, as the drug is not stored to any appreciable extent within the kidney and only one third is recovered in the urine. Heart disease is of course a very inclusive diagnosis and obviously there are cardiac conditions in which the injection treatment of veins would be contraindicated aside from any possible systemic effect from the agent used. In regard to hypertension and hypertensive heart disease, my feeling is that, if there should be any systemic results from quinine, it would be of benefit in vasodilatation and lowering of blood pressure. The experience of Tunick and Nach,¹⁶ and of Cooper¹⁷ indicates that sodium morrhuate is entirely nontoxic. I usually use up to 15 cc, given at multiple points, but I have used 30 cc at one sitting in one individual, with no untoward result. The use of sodium chloride in 15 or 20 per cent solution, invert sugar and the like would have a negligible systemic effect in the amounts administered with the exception of the obvious contraindication to the use of sugar solutions in diabetes.

RESULTS AND COMMENT

From what has been stated it may be noted that 375, or 37.5 per cent, of our 1,000 patients might have been labeled "treatment contraindicated." They were, nevertheless, treated. There were no deaths in the entire 1,000 cases. We have, of course observed an occasional case of vomiting, dizziness or moderate allergic shock after the injection of quinine, but in this particular series, aside from occasional simple syncope,

untoward general reactions were noted in only three patients, all women. The reactions consisted of vomiting and dizziness in one patient, uterine bleeding in one pregnant woman, and uterine bleeding in one non-pregnant woman.

CASE 1—A woman aged 47, with normal physical examination aside from varices had one injection of 0.75 cc of the quinine urethane solution and a second injection of 2 cc eleven days later. Vomiting and dizziness followed the second injection and the treatment was discontinued.

CASE 2—A woman aged 42 with compensated rheumatic heart disease had injections of 2 cc of quinine urethane solution at weekly intervals. After the ninth injection she complained of vaginal bleeding. On questioning, she stated that she had had a few minutes of painless vaginal bleeding after each injection. During this time her menses came at regular intervals as they had always done. She was a multipara who had been married for twenty-five years. Pelvic examination was normal.

CASE 3—A woman aged 43 had her last period four days before starting a series of injections for her veins. Quinine urethane was used at intervals of three weeks. A slight amount of vaginal bleeding occurred immediately after her fourth injection, when she was three months pregnant, and again after her fifth injection when she was three and one-half months pregnant. She told of this five weeks later and the treatment was discontinued. She went on to a normal completion of her pregnancy.

None of the other 997 patients showed any general or remote effect important enough to be noted in the records. Of course many patients with hypertension later suffered from the usual accidents of this disease, such as cerebral hemorrhage or cardiac decompensation. Likewise many of the patients known to have heart disease showed decompensation at some later time, as such patients generally do, but there was no single instance in which there seemed to be any relationship of the decompensation to the treatment. Many of the cardiac patients were undergoing treatment for slight or moderate decompensation during their injection treatment, and their course did not seem altered by the injections. The same can be said of the patients afflicted with pulmonary or kidney disease. No one patient seemed to be made worse by the injection. The few cases of pulmonary or extrapulmonary tuberculosis were not made worse by the injections, nor were those with thyroid disease affected. Likewise no general or unusual local effect was noted in the diabetic patients.

From these results one may take a positive stand, and that is that severe systemic disease is not a contraindication to the injection treatment of varicose veins. McPheeters' exception to the rule (already quoted) is pertinent, viz, the avoidance of sugar solutions (dextrose or invert sugar) in diabetic patients, and kidney irritants (mercuric chloride or metaphen) in nephritic patients.

The general point may further be made that when a patient has one or more of these considered diseases it would benefit his general condition to be rid of varicose veins or their complications, ulcer and phlebitis. This is important for two reasons: first, the presence of discomfort or pain incident to varices and their complications and second, the presence of infection. It is probable that infection is constantly present in the varicose ulcer and in the entire limb that is the seat of such an ulcer, and it may be present in many cases of phlebitis. In injecting varices, one occasionally sees a serious phlebitis or cellulitis follow a technically perfect injection when neither ulcer nor phlebitis has been previously present. This resulting phlebitis or cellulitis

¹³ This is weaker than Genevieve's solution.⁹ The formula for that solution which is identical with the solution on the market in this country consists of quinine hydrochloride 0.133 Gm and urethane 0.067 Gm in each cubic centimeter.

¹⁴ The sodium morrhuate used was supplied by Searle & Co.

¹⁶ Tunick, I. S. and Nach, Robert. Sodium Morrhuate as a Sclerosing Agent in the Treatment of Varicose Veins. *Ann. Surg.* 95:734 (May) 1932.

¹⁷ Cooper, W. M. Use of Sodium Morrhuate in Injection Treatment of Varicose Veins. *Am. J. Surg.* 21:408 (Sept.) 1933.

has all the earmarks of a bacterial infection, and I believe they may be explained by the presence in varicose veins of what de Takáts calls "resting infection", i. e., the presence of bacteria in the vein walls of large varices.¹⁸ More obvious is the infection in the limb affected with varicose ulcer. It is frequent to observe large inguinal nodes on the affected side, which disappear as the ulcer heals. Considering the length of time a varicose ulcer may exist, the effect of its infection may be considerable. It may be profitable to add to the list of common foci of infection large varicose veins, ulcers and phlebitis.

When one applies this reasoning to decide whether or not to treat a diabetic patient, it becomes obvious that if the diabetic patient, of all people, is to avoid infection he should be treated for varices and their complications. From my practical experience, I can reiterate that I have never seen any harmful effect from treating the diabetic patient for varices.

McPheeters¹⁹ of this country was the first to overthrow the notion that varices are not to be treated during pregnancy. He uses a solution of sodium chloride. Recently also Ritchie²⁰ of Edinburgh reported a group of pregnant patients treated with sodium morrhuate without ill effect. In this hospital we have neatly side-stepped the question by adhering to the rule that no pregnant woman is to receive injections for varicose veins. I admit that after the pregnancy is over the engorged veins of the lower extremities or vulva may entirely disappear, or at least diminish in size. For this reason alone it is certainly not proper to attempt a complete sclerosis of the varices during pregnancy. Frequently, however, the woman may suffer from severe pain in some individual segment of the varices, especially in the vulva or upper part of the thigh. Occasionally, too, these varices may be so huge and thin walled as to rupture and give rise to dangerous or even fatal hemorrhage during labor. In private practice I regularly inject such isolated segments of varices during pregnancy. I do not use quinine and urethane because of its oxytocic effect. I use 5 per cent sodium morrhuate, and I have never seen any bleeding or untoward effect, the patients going through their pregnancies as usual.

CONCLUSIONS

A study was made of 1,000 consecutive patients with varicose veins treated in the outpatient department of the Boston City Hospital. Seventy-five of the patients had a preliminary ligation. All were treated by the injection of quinine and urethane, or sodium morrhuate, and a few by solutions of sodium chloride and dextrose, or invert sugar.

Three hundred and seventy-five, or 37.5 per cent, of these patients suffered from at least one complicating serious systemic disease, and, according to previously noted criteria, treatment would have been contraindicated in them. There were no deaths. Aside from syncope there were only three reactions, all in women, consisting of vomiting and dizziness once and uterine bleeding twice.

A consideration of the pharmacology of the substances injected suggests no contraindication to their use in the presence of systemic disease. The removal of pain incident to varices, and ulcers and phlebitis, and the infection present at least in ulcers would seem of

very definite value in the treatment of heart disease, hyperthyroidism, tuberculosis and especially diabetes.

The results obtained from this series of cases would suggest that the injection treatment of varicose veins may be safely employed even in the presence of conditions in which it was previously considered as contraindicated. I agree with the rule that no bedfast patient should be injected for varices.

During pregnancy, the treatment of individual segments of varices that are large or painful is desirable and safe, provided oxytocic substances, such as quinine, are avoided. Sodium morrhuate would seem to be the solution of choice.

Clinical Notes, Suggestions and New Instruments

AXIAL TORSION OF A FULL TERM PREGNANT UTERUS

RALPH A. REIS, M.D. AND ARTHUR J. CHALOUPKA, M.D. CHICAGO

The pregnant uterus usually shows some degree of torsion during the latter half of pregnancy. Such torsion is merely an exaggeration of the physiologic rotation of the pregnant uterus. This usual type of rotation is readily seen at laparotomy, especially at term. It consists of a longitudinal twist of a few degrees. The twist is to the right in 80 per cent of patients and to the left in only 20 per cent. Torsion of this type has no major clinical significance.

True axial rotation of the pregnant uterus is rare and serious. Sudden rotation of the uterus on its long axis through more than 90 degrees may result in premature separation of the placenta, hemorrhage, profound shock and the symptoms of acute peritonitis. When it occurs, it is usually in association with uterine tumors or malformations.

Robinson and Duvall¹ have stated that "without uterine abnormalities there can be no torsion." They believe that extreme torsion, or axial rotation, in the absence of tumors or malformations is due to a developmental asymmetry of the uterine musculature. The following instance of axial torsion of the uterus bears out this statement.

REPORT OF CASE

Mrs. M. S., aged 22, a primipara admitted to the service of Dr. Irving Stein, Aug. 21, 1934, had a previous normal menstrial history. Her last menses began Nov. 16, 1933. Prenatal examinations showed no abnormalities of the uterus. Pelvic measurements showed a typical justo minor pelvis. She had had labor pains for eight hours before admission, at which time she was having moderately severe contractions every five minutes lasting from thirty to forty seconds. Examination at this time revealed that the fetal head was still unengaged.

Two hours after admission the uterine contractions became more frequent, much more severe and lasted from sixty to ninety seconds. After three hours of severe pains, the patient was given one-fourth grain (0.016 Gm.) of morphine sulphate together with $\frac{1}{160}$ grain (0.0004 Gm.) of scopolamine hypodermically. She obtained no relief and one hour later was complaining of constant and almost unbearable pain.

Abdominal examination at this time showed the uterus to be tense and firmly contracted with almost no periods of relaxation. The left round ligament was tense, easily palpable and plainly recognizable through the thin abdominal wall. At this time the left uterine horn and its round ligament insertion appeared to be rotated to the right and anteriorly, so that the uterine horn was almost in the midline. Rectal examination showed the cervix to be effaced, 1 cm. dilated. The membranes were intact and the fetal head was still unengaged.

During the next two hours the uterine contractions gradually became continuous. The patient complained bitterly of pain and of an inability to urinate in spite of an intense desire to do

so. Close observation of the uterus during this period showed the left round ligament gradually shifting to the right until it had crossed the midline just above the level of the umbilicus, and the left uterine horn had rotated to the right until it had come to lie under the right costal arch. The cervix was still undilated and the fetal head was still unengaged. The uterus now became tonic and remained so. There was no evidence of peritoneal reaction or shock. The pulse and temperature were normal. A diagnosis of axial torsion of the uterus was made. All external attempts at rotating the uterus to the left failed, even after the patient was given surgical anesthesia (ethyline).

The abdomen was incised in the midline and when the peritoneal cavity was opened the uterus was found to be rotated on its long axis. The point of rotation was at the junction between the cervix and the lower uterine segment; the direction was to the right that is clockwise viewed from below, and the degree of rotation was approximately 135 degrees. The right round ligament was posterior and somewhat relaxed, whereas the left one was tense and crossed the midline just above the umbilicus. The left horn of the uterus had come to lie under the anterior

Fig. 1—Axial torsion of a full term pregnant uterus in labor. The tense left round ligament can be seen crossing the midline of the abdomen above the level of the umbilicus. Its cornual insertion has been carried under the right costal margin by a clockwise rotation of 135 degrees.

liver margin. This axial twist had dragged the vesical peritoneum and bladder to the right producing marked bladder distortion and thus explaining the inability of the patient to urinate.

All attempts to untwist the uterus failed. A low cervical cesarean section was done and immediately after the fetus and placenta had been removed the uterus rotated spontaneously to the left and assumed its normal relations. Examination of the uterine wall and placenta revealed no evidence of placental separation or hemorrhage. The uterus was then brought out through the abdominal incision and carefully inspected, but no abnormalities could be found. After suture of the uterine incision and replacement of the vesical reflection of the peritoneum, the uterus appeared perfectly normal in its position, axis and relations.

The patient made an uneventful recovery except for a slight wound infection and was discharged from the hospital on the sixteenth day. Involution of the uterus proceeded normally during this time, except for the fact that the uterus seemed markedly displaced to the right. Examination six weeks after delivery showed some dextroversion of the uterus. No other abnormalities could be detected. Involution was complete.

COMMENT

Axial torsion of the pregnant uterus has been known and described by veterinarians since 1662, this condition being rather common in domestic animals, especially cattle. It was first described in the human being by Virchow² who found this condition at autopsy in 1863. Since then there have been many instances (more than a hundred) reported in which the axial torsion of the pregnant uterus occurred in association with fibroid tumors of the uterus or with uterine malformations.

Careful search of the available medical literature reveals only fifteen reports of axial torsion of the uterus at or near term not in association with uterine tumors or malformations. Litten³ collected nine such reports in 1930 and added one of his own. Three other reports have been found prior to 1930 and two others have been published since Litten's publication. The present report is therefore the sixteenth to be published.

An analysis of these sixteen reports shows that age and parity apparently play no role. The patients ranged from 20 to 40 years in age and had had from none to four pregnancies previous to the one during which the axial torsion occurred. One pregnancy was of six months', one of seven months', and two of eight months' duration. Two patients were in the last month of pregnancy and the remaining ten were at term.

The onset of the uterine torsion was sudden in six. None of these had reached term. In all of these, the symptoms were acute in onset and fulminating in character. The symptoms present in this group were those of shock and collapse following immediately on the onset of severe abdominal pain and vomiting. The clinical picture in each of these was that of an acute intraperitoneal crisis. In two of these the development was so rapid that death occurred within three hours, and the diagnosis was established only by postmortem examination. Two other patients died within a few hours after hysterectomy was performed, the remaining two in this group recovered following cesarean section.

The onset was gradual in five others and was not mentioned in the remaining five reports. In none of these ten were the symptoms either acute or fulminating. All of these ten patients recovered.

It would seem that axial torsion of the pregnant uterus is serious only when the torsion is rapid enough to produce acute circulatory disturbances in the uterus which result in peritoneal insult. In all ten of these patients the axial torsion developed during long and difficult labors, many of which were characterized as "obstructive" in nature.

The axial torsion was undiagnosed in fourteen, being found either at autopsy (in two) or on laparotomy (in twelve). Litten made the diagnosis in his patient from the abdominal manifestations alone. His patient was very thin, and the round ligament could be seen and felt as it passed from its inguinal canal insertion to the opposite side of the abdomen. There was a marked hydramnios present in association with an anencephalic monster. After a number of hours of hard and ineffectual labor, he ruptured the membranes artificially to relieve the uterine distention. The uterine torsion promptly disappeared and the patient delivered spontaneously. Subsequent postinvolutional roentgenographic examination of the uterus with the aid of iodized oil showed the uterus to be sinistraverted. This was undoubtedly an instance of gradual axial torsion of the pregnant uterus but unfortunately was not proved by direct visualization. As far as can be determined the present example is the first in which a preoperative diagnosis of axial torsion of the pregnant uterus was confirmed by the finding of this condition during laparotomy.

The degree of rotation of the uterus ranged from 90 degrees to 360 degrees. Here again a differentiation must be made between the "fulminating" group and the group in which the onset was "gradual."

In the former, the rotation was 180 degrees or more in every instance, whereas in the latter group it was 180 degrees or more in only four of the ten patients. The direction of rotation was clockwise in twelve and counterclockwise in four. The level of rotation in the seven reports in which mention was made of this point was at the uterocervical junction in two, the midcervix in three and the cervicovaginal junction in two.

Fig. 2—Axial torsion of a full term pregnant uterus in labor. The drawing indicates the clockwise rotation with displacement of the path of the left round ligament and the torsion traction to which the bladder was subjected.

² Virchow Rudolf. Die Krankhaften Geschwulste. Berlin 3. 1863.
³ Litten L. Zentralbl. f. Gynak. 54: 2009 (Aug. 9) 1930.

Two patients in the "fulminating" group died before treatment could be instituted. Two others were treated by hysterectomy and died within a few hours, the remaining two recovered following cesarean section. Nine of the ten patients in the "gradual" group were treated by cesarean section, all recovered except one patient, in whom there had been previous attempts at version and extraction. This patient died three days later of septicemia. These attempts at version and extraction must be held at least partially responsible for this fatality. The development of a "gradual" axial torsion of the uterus would seem to be comparatively harmless to the patient if this condition is not permitted to continue over too long a period of

that uterine asymmetry must be present to permit of axial torsion of the uterus explains the production of this condition in those patients in whom there are neither tumors nor malformations of the uterus nor gross lateral uterine deviations. However, Vogt,⁴ Gliniski⁵ and Lohlein give such accurate descriptions of the uterus in their reports that it must be conceded that these uteri were normal.

SUMMARY

1 The instance of axial torsion of a pregnant uterus at term here reported is the first in which the correct diagnosis was made from physical examination and confirmed by laparotomy.

time. The axial torsion was unsuspected in eight of the ten in the "gradual" group.

The various factors that have been described as being causative of axial torsion are postoperative adhesions, irregular fetal movements, weak abdominal muscles, umbilical hernia, manual labor and the like. Analysis of these sixteen reports seems to indicate that the cause of the "fulminating" type is unknown at present.

The one factor present in every one of the ten patients in the "gradual" group was a long hard labor without progress. This common factor should not be overlooked in searching for the etiology of this condition. There must also be some predisposing factor such as a malfunction of the uterine musculature. At least some type of uterine asymmetry must be present. Such asymmetry was present in several cases including the one here reported. The dictum of Robinson and Duvall

2 A study of the sixteen reports gathered together leads to a division of this condition into two definite clinical groups.

3 The "fulminating" type is characterized by a sudden onset with severe pain and the symptoms of shock and intraperitoneal insult. The degree of torsion is 180 degrees or more. The etiology is unknown. This type is rapidly fatal in most instances.

4 The "gradual" type is characterized by a gradual development. It frequently presents no symptoms or changes and is discovered only by accident at laparotomy. The degree of rotation varies from 90 to 200 degrees. This type follows long severe obstructive labor. The predisposing cause is probably an asymmetry of the uterine musculature.

Plans for a study of the several serologic tests and modifications of preexisting methods developed in this country for the diagnosis of syphilis have already been published¹. The purpose of this study was to determine the reliability of the several serodiagnostic methods used in the United States. The project has been

nary practice. Twelve hundred specimens of blood and spinal fluid were collected in the different clinical groups in sufficient quantity to furnish each participating serologist with a comparable sample. Samples of blood and spinal fluid were collected from donors in various categories and distributed from central points of collection to the laboratories of participating serologists. A general invitation was extended to serologists in this country who had described an original serologic test or a modification of a preexisting test. Those who had described more than one serologic test delegated the performance of the second test to another laboratory in a different city.

The donors were carefully chosen and accurate records were made of the pertinent facts in the history and physical examination. Reasonable care was taken to insure that donors would be available for clinical reexamination in the event that discrepancies existed in the reports of the participants. Whole blood specimens were collected in dry sterile glass syringes under aseptic conditions transferred to uniform glass tubes, and stoppered with sterile corks. Spinal fluid specimens were collected under aseptic conditions directly into uniform glass tubes.

Specimens were collected daily over a period of three months, carefully packed, and shipped in double metal mailing containers conforming to U S Postal Regulations. All specimens were transported either by special delivery mail or by special delivery air mail, the mailing time being so arranged as to assure simultaneous delivery at all points. There were 1,017 blood

sponsored by the U S Public Health Service at the request of the American Society of Clinical Pathologists. A committee consisting of two syphilologists, two clinical pathologists and one officer of the Public Health Service was appointed by the Surgeon General of the Public Health Service to organize and conduct the evaluation study. This work has been completed.

In general, the results achieved are a great credit to the participating serologists. The investigation has followed, as far as possible, the conditions met in ordi-

specimens each divided into fourteen comparable samples, and 220 spinal fluid specimens each divided into thirteen comparable samples. Dr William A Hinton of Boston did not participate in the examination of spinal fluids. A total of 14,238 comparable blood samples and 2,860 comparable spinal fluid samples were collected exclusive of those taken for serologic retesting. One of the samples of blood or spinal fluid from each donor was shipped as a control to a station of the Public Health Service to determine the physical condition on delivery. An important point in the evaluation plan was the assignment of a code letter as a substitute for the name of each participating serologist. The identity of the serologists performing the tests was,

therefore, unknown to the members of the committee until after the evaluation had been completed

Samples were sent to the following serologists

Walter V Brem, Los Angeles
Harry Eagle, Philadelphia
William A Hinton, Boston
F M Johns New Orleans
Reuben L. Kahn (performing Kahn standard diagnostic test), Ann Arbor, Mich
B S Kline (performing Kline diagnostic test), Cleveland
John A Kolmer, Philadelphia
M B Kurtz (performing Kahn presumptive test), Lansing, Mich
N H Lufkin and F Rytz, Minneapolis
Charles R Rein (performing Kline exclusion test), New York
E Henry Ruediger, San Diego, Calif
Capt W C Williams (U S Army), Washington, D C
Emil Weiss, Chicago

Drs Brem, Kolmer and Ruediger, and Captain Williams performed complement fixation tests. All others performed flocculation tests. All of these workers are to be complimented for the spirit of

cooperation and the interest shown by them during the entire study. In some instances the work was done at great sacrifice of individual time and effort.

The fifteen clinical groups from which donors were selected and the number of donors included in each were as follows:

Blood Specimens

- 43 untreated patients with primary syphilis
- 65 untreated patients with early secondary syphilis in the eruptive stage.
- 307 patients with late syphilis* with varying amounts and kinds of treatment.
- 152 normal presumably nonsyphilitic individuals
- 25 normal presumably nonsyphilitic women, both during menstruation and in the intermenstrual interval
- 46 presumably nonsyphilitic patients with acute febrile diseases (temperature above 38 C, or 100 F) or physically induced artificial fever above 40.5 C (105 F)

2 For purposes of this study the term late syphilis is used to designate syphilis of two or more years duration. This follows the generally accepted arbitrary classification.

51 presumably nonsyphilitic patients with jaundice due to various causes

50 presumably nonsyphilitic patients with leprosy

36 presumably nonsyphilitic patients with malaria.

62 presumably nonsyphilitic patients with malignant neoplastic disease

53 presumably nonsyphilitic patients with tuberculosis

54 presumably normal pregnant women

10 syphilitic or nonsyphilitic patients, from each of whom a larger volume of blood was collected and divided into forty-two samples. Three of these were submitted simultaneously to each serologist, each sample under a different key number.

Spinal Fluid Specimens

110 patients with syphilis of the central nervous system

110 patients with nonsyphilitic psychoses and other mental abnormalities

Chart 1—Sensitivity of blood tests based on the percentage of positive reports in a group of 415 patients with syphilis contrasted with the specificity of blood tests based on the percentage of negative reports in a group of 152 normal presumably nonsyphilitic individuals

EVALUATION OF SENSITIVITY

The three groups of syphilitic donors of blood specimens permit an estimation of the degree of sensitivity of the thirteen serologic procedures. The early primary and the late syphilis groups are especially suitable for

this purpose. As would be expected, almost all the tests were positive in the group of donors with untreated secondary syphilis. The percentage of positive reports of the thirteen tests in each of these three groups together with the percentage of positive reports of the serologic tests for all syphilitic blood specimens will be found in table 1. The percentage of positive reports was obtained by dividing the number of positive reports by the total number of specimens examined. The specimens examined by each serologist represent the total number submitted in each group of syphilitic donors less the number reported as hemolyzed, as physically damaged or as not received.

The committee has found the evaluation of doubtful reports impracticable. A logical method is lacking for determining the amount of credit to be assigned or the deduction to be made in respect to such reports. There was no general agreement in the proposals offered by the participating serologists for the evaluation of this group of reports. Throughout this study specimens giving doubtful reactions are included in the columns headed "specimens examined" but are not counted as positive or partially positive reports in determining percentages of positive reports or percentages of negative reports. Although in this study the doubtful reports have been given a negative rating, the committee recognizes that in clinical practice a doubtful report may often be of value.

When more than half of the serologic reports on a specimen of blood from a patient suspected of having syphilis were negative, the patient, with a few exceptions, was subjected to a thorough clinical reexamination and to any indicated special examinations.

The result of this is a slight lowering of the general rate of sensitivity, affecting all participating serologists equally.

EVALUATION OF SPECIFICITY

The specificity of the various serologic tests has been estimated from the group of blood specimens from normal presumably nonsyphilitic individuals. All of these

Chart 2—Sensitivity of spinal fluid tests based on the percentage of positive reports in a group of 110 neurosyphilitic patients contrasted with the specificity of spinal fluid tests based on the percentage of negative reports in a group of 110 nonsyphilitic patients with other mental diseases.

donors were included in a selected group in which the prevalence of syphilis was believed to be lower than the average for the whole population. The group con-

Patients with untreated primary syphilis were not reexamined, because treatment had been instituted immediately after the blood specimen had been taken for the evaluation study. The original diagnosis of primary syphilis, based on the dark field examination, was considered as final.

In the cases of late syphilis, there were fifteen instances in which the serologists uniformly reported negative results. The committee realizes that some of these negative results are due to the effects of treatment and represent correctly the serologic status of the

sisted entirely of medical students and members of the staff of a medical school and hospital. The total number of specimens examined, the number of false positives reported by the thirteen serologists, the percentage of false positive tests, and the percentage of negative reports are given in table 2.

The donors in the normal presumably nonsyphilitic group on whom more than one positive or more than two doubtful results were reported were serologically reexamined by the participating serologists and given a clinical reexamination by one or more syphilologists.

* Performed modification of complement fixation tests

† Performed Kahn presumptive test

‡ Performed Kline exclusion test

Only the original serologic report was considered in computing the percentage of negative reports

In table 3 and chart 1 will be found a summary showing the sensitivity of blood tests based on ability to detect syphilis contrasted with the specificity of blood tests based on ability to exclude syphilis

EVALUATION OF THE REPORTS ON SPINAL FLUID SPECIMENS

In table 4 and chart 2 may be found the total number of specimens of spinal fluid examined by the twelve participating serologists who examined spinal fluid specimens, the number of positive reports in syphilitic patients, the number of false positive reports, and the percentage of positive and negative results

Clinical and serologic reexaminations were made on all presumably nonsyphilitic patients with psychoses or other mental abnormalities having more than one positive or more than two doubtful reports. Only a clinical confirmatory reexamination was made on patients with syphilis of the central nervous system whose serologic reports were predominately negative

Chart 3—Percentage of positive serologic tests for syphilis found in blood specimens from presumably nonsyphilitic patients with leprosy

SPECIAL SEROLOGIC PROBLEMS

In addition to an evaluation of the various sero-diagnostic methods as applied to normal presumably nonsyphilitic and to syphilitic individuals, the members of the committee have thought it desirable to obtain data on the results of tests on blood specimens from groups of patients suffering from certain clinical conditions other than syphilis. The presence of syphilis in the donors of these groups has been excluded with reasonable certainty, although this could not be absolutely assured in every case. Because of the meagerness of the data obtained from these special studies, the results have not been included in the serologic evaluation. For this reason the results of the serologic examinations in these special groups are reported separately in table 5. The committee is impressed with the need for further serologic studies in certain of the groups with a view to determining the possibility of nonspecific positive serologic reactions or an increased proportion of positive reactions in syphilitic individuals. The percentages of false positive reports in presumably nonsyphilitic normal donors, as shown in table 2, are compared in table 5 with the percentages of positive results reported for the special disease conditions studied. Attention is particularly directed to the

great difference in these percentages in the leprosy group (chart 3). This difference was greatest in the leprosy patients and considerably less in the malaria group. The patients on whom discrepant reports had been made except the lepers were with few exceptions reexamined serologically and clinically in the same manner as the normal presumably nonsyphilitic donors on whom discrepant reports had been made. The presumably nonsyphilitic donors with leprosy were not reexamined serologically but were reexamined clinically. Special histories were also taken in order to eliminate frambesia as a factor in leprosy patients who had previously dwelt in the tropics.

Another of the special studies was concerned with the possible influence of menstruation on serologic reactions. The serologic observations are contained in table 6.

DAMAGE TO SPECIMENS

There were very few instances of hemolyzed or anticomplementary specimens or leakage due to broken tubes. The leakage of spinal fluid specimens occurred chiefly in those sent to California by air mail. It has

The studies of the committee, based solely on the information derived from the evaluation of these reports, show that if two tests are to be performed it is immaterial whether two complement fixation tests, two flocculation tests or a combination of one flocculation test and one complement fixation test are selected.

As a secondary consideration, in the choice of one or more tests for general use, due regard should be given to the cost, rapidity and ease of performance. No consideration was given to these factors in this evaluation project. Certain tests that may be performed rapidly on blood specimens appeared to yield results comparable to those obtained with tests requiring a longer period for their performance.

There is some evidence that a properly performed, highly sensitive flocculation test might be used as a routine for the purpose of excluding the likelihood of syphilis. If a negative result is obtained by such a method it is quite likely that it will be negative by any other method. If the test yields a positive result it should be repeated and compared with one or more highly specific flocculation or complement fixation tests.

been suggested that this leakage was due to changes in atmospheric pressure in the high altitudes (14,000 to 18,000 feet) to which these specimens were subjected.

CONCLUSIONS

The ideal serodiagnostic tests for syphilis should possess both specificity and sensitivity. They should be adaptable to the diverse and at times unfavorable conditions existing in ordinary practice. Tests that are reliable when performed with hemolyzed, anticomplementary or contaminated serums or spinal fluid specimens are obviously of more value to the clinician than those which cannot be used under such conditions.

This study indicates relatively equal value to the clinician of efficient complement fixation tests and efficient flocculation tests as applied to either blood or spinal fluid specimens. This study further reveals that, while most flocculation tests are approximately equal in value to complement fixation tests when applied to spinal fluid specimens, it is apparent that certain of the flocculation methods are relatively inadequate.

The results of this study indicate that, in spite of the difference in symbols that are customarily used in reporting the results of various tests, it is satisfactory to report results as merely "positive," "doubtful" or "negative." The committee recommends this simple method of reporting qualitative tests to all serologists. Its adoption should be of great help to the clinician.

The committee appreciates that the actual serologic testing performed in this study has been done under relatively ideal conditions and that the results do not necessarily compare with those obtained from serologic methods as generally employed.

All the material contained in this report, together with the charts and tables from which these data were derived and abstracts of the serologic methods employed, will appear in a forthcoming publication of the United States Public Health Service. For further information the reader should write to the Surgeon General, U. S. Public Health Service, Washington, D. C.

GLANDULAR PHYSIOLOGY AND THERAPY

THE ADRENAL MEDULLA

J. M. ROGOFF, MD
CHICAGO

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed, the series will be published in book form.—Ed

Glandular therapy is based chiefly on the capacity of hormones or other products, obtained from endocrine glands, to substitute for deficiency or absence of function of those organs in the body. Although the adrenal medulla has been studied extensively, both experimentally and clinically, its function has not been explained satisfactorily. Yet its hormone, epinephrine, is one of the most commonly used drugs in the practice of medicine and surgery. The present purpose, therefore, can best be accomplished by discussing available physiologic and pharmacologic information in the light of or with special emphasis on its therapeutic application. In view of the vast literature on the subject, no attempt will be made to include a comprehensive review or to quote original references for all the sources of information. These can be found in readily accessible reference books.¹ For detailed anatomic and other information the reader is referred to Biedl,² and for cytologic description to the chapter on the suprarenal bodies in *Special Cytology*.³

The mammalian adrenal gland represents an anatomic union of two glands, different in origin, structure and physiologic significance. In certain lower forms (e. g., elasmobranchi) these two glands exist as separate structures. The interrenal body corresponds to the cortex of the mammalian adrenal and the paired chromaffin bodies, in intimate anatomic relation with the sympathetic ganglions, correspond to the medulla. So little is definitely known concerning the function of either that, from a clinical standpoint, the suprarenal body has been regarded as a single gland. Whether or not there is a functional correlation between the medulla and the cortex which surrounds it is not known. A hormone (epinephrine) has been isolated in crystalline form from the medulla and the presence of a hormone (interrenalin) in the interrenal gland substance or cortex has been demonstrated by the late Professor G. N. Stewart and myself since 1925, and this has been confirmed more recently by a number of other workers, although it is not yet possible to obtain it in pure form.

The cells of the adrenal cortex are of mesoblastic origin. The rounded or polygonal cells of the adrenal medulla are derived from the neural ectoderm, in common with cells of origin of the peripheral part of the sympathetic nervous system. They are arranged irregularly in groups or anastomosing columns, between which are networks of blood capillaries. These capillaries become dilated in areas, forming relatively large blood sinuses. In the medulla is found an abundance of sympathetic nerve fibers. These facts are significant

in view of the knowledge that the rate of blood flow through the adrenal glands is greater than that of any other organ in the body (with the possible exception of the thyroid) and that the internal secretion of the medulla (epinephrine) is regulated through the influence of the sympathetic nervous system.

Some writers support the view that there is more than a mere anatomic relationship between the cortex and medulla of the adrenal gland. It has been held that histophysiologic transitions exist between the cortical and medullary portions of the gland. Others believe that material, which is to become epinephrine, passes through initial stages of preparation in the cortex, the final process being completed in the medulla. The suggestion has been made that the cortical cells manufacture epinephrine from tryptophane. Certain authors have stressed the presence of epinephrine in the cortical layers of the adrenal. Apart from interpenetration of the cortical structure by medullary cells, however, there is no good evidence that the cortical cells elaborate or store epinephrine. Further, in the interrenal body of lower forms chromaffin material does not exist.

The suggestion may be made that a certain degree of functional interdependence between cortex and medulla evolves as we advance from lower to higher biologic forms and that this leads to a more intimate anatomic relationship. In the adrenal of birds, the cells of the interrenal gland substance are interspersed with the chromaffin cells. Whatever may be the significance of the various anatomic relations between the chromaffin and the interrenal gland cells in the different forms, it is not likely that the functional explanation rests on a capacity of the interrenal tissue to elaborate epinephrine for the medulla. It seems more probable that, if a functional interrelationship exists between the cortex and the medulla of the adrenal gland, the indispensable function of the cells of the cortex, or of the hormone elaborated by them, is in some manner aided by the less vitally essential product of the cells of the medulla. Indeed, this possibility is suggested by some unpublished observations that I made in the course of investigations on the adrenal cortex. It was found that the action of extracts made from the medulla, by the same process as those obtained from the cortex, sometimes were effective in resuscitating adrenalectomized animals from coma and that when employed together with cortical extract seemed to increase its potency. Whether such action, if genuine, is due to epinephrine or to some other product of the medulla is not known. These incidental observations require further investigation.

The presence of epinephrine in the cells of the adrenal medulla imparts to them a special affinity for chromic stains, hence the terms "chromaffin" and "chromophil" tissue as commonly applied to these cells. Chromic stains produce a brownish color with epinephrine. With ferric chloride, epinephrine yields a green color, which turns reddish on the addition of alkali. The ferric chloride reaction was employed by Vulpian as early as in 1856 to demonstrate that the substance elaborated in the cells of the adrenal medulla is found in the adrenal vein blood. A rose color is produced with epinephrine on addition of corrosive mercuric chloride and sodium acetate or by the action of iodine. These color reactions are too feeble to be useful for detecting epinephrine in high dilutions.

For dilutions up to about 1:3,000,000, the blue color produced by Folin's phosphotungstic acid reagent is a

reliable reaction for epinephrine. This reagent, however, yields the same color with uric acid and other substances, which limits its usefulness as a test for epinephrine in blood. Nevertheless, it is quite satisfactory for quantitative determinations of epinephrine in commercial solutions or in the adrenal glands. For assaying the concentration of epinephrine in blood the much more sensitive biologic reactions must be employed. The method employed by Stewart and Rogoff in their studies on the rate of epinephrine secretion from the adrenals will be briefly described later.

Epinephrine is a simple amine and in its chemical reactions it resembles the alkaloids. Its structure is related to tyrosine and it can be prepared synthetically from catechol. The synthetic, racemic salt when acted on by methyl alcohol is converted into *d*- and *l*-epinephrine. The natural epinephrine is *l*-methylaminoethanol-catechol, which is identical with the levorotatory synthetic product. This has about fifteen to twenty times the physiologic potency of the dextrorotatory product, and the racemic compound possesses about one-half the physiologic value of the natural base. Solutions of epinephrine are readily oxidized on exposure to air, yielding a pink color. This color reaction has been utilized in devising a method for quantitative determinations of epinephrine in solution.

Oliver and Schaefer were the first to observe that the adrenal medulla stores a product which is capable of remarkably elevating the blood pressure. Saline or watery extracts of the medulla, when introduced into the circulation, caused a marked rise in blood pressure, while similar extracts made from the cortex of the gland failed to produce this effect. Later, the active material from the medulla, epinephrine, was isolated in pure form and its identification led to its synthesis. The property of elevating the blood pressure has been utilized as a means of determining the quantity of epinephrine in the glands, in the adrenal vein blood and in commercial solutions.

To determine the rate of secretion of epinephrine, a method should permit estimation of the blood flow through the gland and the concentration of epinephrine in the blood. This fulfils the elementary essentials for measurement of a velocity, i. e., measurement of a time and a mass. The most satisfactory method for quantitative determination of the concentration of epinephrine in blood is that employed extensively by Stewart and Rogoff in studies on the rate of liberation of epinephrine from the adrenal glands. The procedure for determining epinephrine output is as follows. Veins entering the vena cava, excepting the adrenal veins are ligated or clamped so that a pocket can be formed by occluding the cava beneath the diaphragm and below the entrance of the adrenal veins. Into the "cava pocket" only blood from the adrenal veins can enter. The blood can be released into the circulation (for auto-assay with the aid of denervated organs) by releasing the clamp at the diaphragm or it can be collected through a cannula inserted in the lower end of the pocket by releasing the lower clamp (the upper clamp remaining). Collection of blood through the cannula is timed, the quantity of blood measured and the rate of blood flow during the collection thus determined. The epinephrine concentration in the adrenal blood is then determined by its action on a segment of rabbit's intestine and, when necessary, this is confirmed on a segment of nonpregnant rabbit's uterus. The tone and contractions of the intestinal segment are inhibited by epinephrine, while the opposite effect is caused on the uterus. These

effects, within limits, are proportional to the concentration of epinephrine. The concentration of epinephrine in the blood and the rate of blood flow through the adrenal glands having been determined, it is a simple matter to calculate the rate of epinephrine secretion. There are, of course, many important details that must be observed and the method has its limitations. When properly employed, however, it is remarkable how well repeated results agree and reliable information is obtained. Results obtained by this or by any other method in which anesthesia is employed should not be interpreted, without further consideration, as applying to the non-anesthetized animal or man. But different kinds of anesthetics or varying depths of narcosis do not appear significantly to alter the rate of epinephrine output.

By this method, the rate of epinephrine secretion from the adrenal glands, under ordinary experimental conditions, has been determined in a large series of cats and dogs and in a number of monkeys. Employing volatile (ether, chloroform) and nonvolatile (urethane, amytal, chlorbutanol) anesthetics for the surgical procedures in the method, Stewart and Rogoff determined the average epinephrine output, in these animals as about 0.00025 mg per minute per kilogram of body weight. This can be increased by stimulation or diminished by section of the nerve supply to the adrenals. The rate of epinephrine secretion can be influenced, in either direction, by the action of certain drugs (e. g., strychnine, nicotine, physostigmine, curare). The alleged increase of epinephrine output in traumatic and in anaphylactic shock has been found not to occur in anesthetized animals.

It seems strange that an important role in the body cannot be attributed to the epinephrine secretion. This hormone yields definite reactions, quantitative information on its rate of secretion under different conditions is available, and control of the secretion through nervous mechanisms has been well established. Yet, though it lends itself readily to experimental study, no specific function for epinephrine has been proved. Indeed, it has been well established that, if it has a function in the body, it is not indispensable for life and health, for it is possible to suppress the secretion of epinephrine (by excision of one adrenal and complete denervation of the opposite gland with or without destruction of its medulla) without apparent influence on the life and health of the animal.

The theory of an "emergency function" of the adrenals is based on the concept that epinephrine is not secreted under ordinary conditions and that outbursts of epinephrine enter the blood stream at times of special stress.⁴ The experimental support for this theory is an attempt to prove a significant liberation of epinephrine from the adrenals under the influence of asphyxia or of stimulation of sensory nerves.⁵ However, the quantitative studies, made by Stewart and Rogoff,⁶ on the liberation of epinephrine indicate that the secretion is continuous, and they failed to demonstrate any significant alteration in the rate of output.

under these conditions. Of course, their experiments were performed on anesthetized animals, as were those on which the "emergency" theory is based. The original studies, by Cannon and his collaborators, were made with a method which was later discarded in favor of the so-called denervated heart as an indicator for changes in the epinephrine output.⁷ Repeating their experiments with this method, we found that the reactions obtained by them, on which the emergency theory rests, could be obtained with the "denervated heart" after epinephrine secretion was abolished or the adrenal glands excised.⁸ Cannon at first maintained that acceleration of the denervated heart did not occur in the absence of epinephrine secretion but later he also got positive results. He explained the acceleration in absence of the adrenals as the result of action of other substances, viz., products of the thyroid, liver, and so on. More recently he has reported the cardio-accelerator action of a substance, designated "sympathin".⁹ It is maintained that these substances account for the acceleration of the denervated heart in the absence of epinephrine but it is not clear why the reaction failed, in the absence of the adrenals, in Cannon's earlier experiments. Whatever may be the significance of these cardio-accelerating substances, it is evident that if they account for acceleration of the denervated heart in the absence of the adrenal glands, the denervated heart as employed should not be relied on for "quantitative" measurements of changes in the epinephrine output from the adrenals.

Other theories of function of epinephrine have been submerged by the extensive literature on the emergency theory. It seems that some of the older theories offer better explanations for the function of this hormone. There is no good evidence that epinephrine plays a role in the maintenance of normal blood pressure. Suppression of epinephrine secretion causes no significant change in the blood pressure. It has been shown that epinephrine can exert an action on the heart when secreted at the ordinary rate. We have observed some reactions also that indicate the possibility of an effect as an adjuvant to the action of sympathetic nerves. Older observations supporting the view that the adrenal medulla plays an important part in carbohydrate metabolism were based largely on the effects of pharmacologic quantities of epinephrine, which are much larger than the adrenals have been found capable of secreting. Zuelzer's theory of an antagonism between epinephrine secretion of the adrenal medulla and the internal secretion of the pancreas lacks substantial experimental support. Stewart and Rogoff¹⁰ found that experimental pancreatic diabetes can be readily produced in the absence of epinephrine secretion from the adrenals. Hyperglycemia and glycosuria were as quickly developed and reached as high a level as in depancreatized animals without interference with the adrenals, if the animals made a satisfactory recovery from the surgical procedures. More recent studies by various investigators have failed, thus far to establish

a definite relationship between the adrenal medulla and pancreatic diabetes. Existing experimental evidence of an influence of calcium salts on epinephrine action is interesting in the light of the hypercalcemia that occurs in adrenalectomized animals. The probable interrelationship between the parathyroid and adrenal glands recently reported,¹¹ may be concerned with the adrenal medulla, although the evidence at present relates it to the cortex.

The concept that epinephrine aids in maintaining normal blood pressure originated from the observation that low blood pressure is one of the characteristic symptoms of severe adrenal disease (Addison's disease). It also follows from the fact that extracts of the medulla, when introduced into the circulation, cause a marked rise in pressure. The idea has been maintained that epinephrine plays an important role in conditions associated with hypertension. Recent unpublished experiments that are still in progress, in which actual measurements of epinephrine concentration in the general blood of patients with hypertension were attempted, failed to demonstrate detectable quantities. In hypertension experimentally created by renal ischemia, it was found by Goldblatt and his co-workers¹² that epinephrine secretion was not a factor. Hypert thyroidism and a number of other conditions are often believed to be due to or associated with an excess of epinephrine secretion from the adrenals. On this assumption surgeons have recommended excision of an adrenal gland or denervation of one or both glands. Notwithstanding the benefit supposed to be derived, the practice of these operations should be deprecated. The experiences of those who have performed many experiments with the adrenals, involving surgical procedures, show that these operations involve great risk to life. It seems, therefore, that the meager basis for assuming hypersecretion of epinephrine in certain diseases does not warrant the risk of such operations on human beings as a therapeutic measure. Even if the existence of hyperepinephremia were proved, denervation as practiced could not be expected to afford permanent relief, since it is well known that nerve regeneration can occur within a few weeks. Nor can it be hoped that excision of one adrenal would prove beneficial since compensatory hypertrophy or functional compensation of a remaining organ may be expected when its mate is excised. This, of course, does not apply in cases of unilateral tumor of the adrenal medulla, e. g., paraganglioma.

Unlike well known products of other endocrine glands, the therapeutic value of epinephrine does not depend on capacity to substitute for lack of physiologic endocrine function of the gland from which it is derived. For, as already mentioned, the function of the adrenal medulla is still quite obscure and its secretion of epinephrine is not indispensable for life and health. The value of epinephrine as a therapeutic agent depends primarily on its pharmacologic actions on the circulatory apparatus. A brief summary of the therapeutic uses of epinephrine in surgery and in internal medicine has been published by Richardson¹³ and by Christian.¹⁴

Epinephrine is most effective in its action on the circulation when administered intravenously. Oral administration cannot be said to yield physiologic effects and it may result in distressing gastric irritation. Intramuscular injection permits better absorption of the drug than subcutaneous administration, especially when followed by local massage. Subcutaneous introduction of epinephrine results in local vasoconstriction, which retards its absorption. But it has been found by Luckhardt and Koppányi¹⁵ that massage of the area of an epinephrine injection gives a hemodynamic effect some hours after the injection, if deep anesthesia is avoided. Barbour and Rapoport¹⁶ found that epinephrine is more readily absorbed from the rectum than from the colon. Rectal absorption yielded a greater rise in blood pressure, though glycosuria was more readily obtained when the drug was absorbed from the colon. Glycosuria is also more readily obtained by subcutaneous than by intravenous administration, while the reverse is true of the blood pressure effect. Supposed differences in susceptibility to epinephrine may be explained by differences in rate of absorption of the drug when administered by subcutaneous or intramuscular injections. Local application of epinephrine, as a styptic, depends on its capacity to constrict arterioles and capillaries. Vasoconstriction may be followed by dilatation and in local application to the nasal mucous membrane, e.g., in hay fever temporary benefit may be followed by aggravation of symptoms. This may apply to other conditions in which epinephrine is employed locally.

The predominant action of epinephrine is produced on tissues that are supplied with nerves from the sympathetic system. Its effect on an organ is the same as that which is obtained on stimulation of the sympathetic innervation of the organ. This action has been termed "sympathomimetic" by Barger and Dale. When the sympathetic nerve supply to an organ is sectioned and the nerve endings are allowed to degenerate, the organ becomes more sensitive to the action of epinephrine. This indicates that the effect of the drug is exerted on the myoneural junction and not on the nerves or their endings. Langley has suggested that a "receptive substance" in the cell protoplasm, which is affected by epinephrine becomes more sensitive when the cell is deprived of the influence of its nerve supply. The increased sensitivity of denervated organs to epinephrine renders them useful as indicators for epinephrine, when employed under proper conditions. The usual effect of epinephrine on smooth muscle is abolished or reversed by the action of ergotoxine or apocodeme. Thus, a dose of epinephrine that causes vasoconstriction and an elevation of blood pressure will fail to elevate the pressure or may cause a fall following the action of these drugs. In some animals a fall is produced by very small doses of epinephrine, while larger doses cause a rise. Dragstedt,¹⁷ however found that, in the unanesthetized animal doses comparable with and administered at the ordinary rate of epinephrine secretion are capable of causing a rise in blood pressure.

The vasomotor action of epinephrine renders it exceedingly valuable in combating acute circulatory col-

lapse especially in traumatic shock or accidents of anesthesia. Its effect, however, is of short duration and its use should be supplemented by measures that give more lasting benefit. Epinephrine is easily oxidized and when introduced into the circulation it is so rapidly destroyed that an effective concentration in the blood is maintained for only a brief period, hence its evanescent effect on the circulation. As an emergency measure, therefore, it is usually necessary to administer the drug in more than one dose, until improved blood flow through the circulatory mechanism leads to recovery or until other effective treatment has been substituted. For such treatment, 2 or 3 minims (0.1 or 0.2 cc) of 1:1,000 solution of epinephrine hydrochloride well diluted with physiologic solution of sodium chloride, usually suffices for intravenous administration. It should be borne in mind that, while epinephrine elevates the blood pressure, its vasoconstrictor action retards capillary circulation. Thus, the blood flow through important structures may be diminished at a time when increased circulation is desired. It is generally advantageous, therefore, to increase the volume of circulating fluids by intravenous injection of saline solution. The addition of epinephrine at intervals, in such amounts as to permit a sustained rise in blood pressure, combines the immediate brief effect of the drug with the more lasting value of the added physiologic fluid until the augmented circulation through the cardiac centers facilitates recovery.

Administration of larger quantities of epinephrine than the dose required to elevate the blood pressure effectively may lead to dangerous consequences. The heart, in shock, may not be able to withstand a sudden, high elevation of pressure resulting from powerful vasoconstriction, and acute dilatation may be fatal. Stimulation of the vagus center, as a result of sudden increase in blood pressure may lead to serious cardiac inhibition. 'Delirium cordis' may result from excessive action of epinephrine on the heart. Other possible, untoward effects may occur. There is some question whether ventricular fibrillation is more readily caused by larger doses of epinephrine than by small ones. The weight of opinion, however, is that larger doses cause this toxic effect, although it is conceivable that under certain conditions or in susceptible individuals the smaller dose may do this. Thus the desired therapeutic effect may easily be defeated by indiscreet use of the drug. Especially is this the case when epinephrine is injected directly into the heart as an extreme measure in cardiac standstill. An excellent editorial¹⁸ on intracardiac injection of epinephrine was published in THE JOURNAL in 1923. With appropriate dosage, this procedure has proved valuable in causing the heart to resume beating if arrest of heart action has not existed more than ten minutes. Stewart, Guthrie and Pike have shown that the medullary centers cannot be resuscitated if cerebral anemia has been induced for more than about fifteen minutes.

Since epinephrine secreted at the ordinary rate can exert an influence on the heart, to produce a physiologic effect it should be necessary only to raise the concentration of epinephrine in the blood to an effective level above the ordinary concentration. Calculating from the rate of output of epinephrine from the adrenal glands, even if none were destroyed in the pulmonary circulation the average epinephrine concentration in the general circulation would be approximately from

1 2,000,000,000 to 1 1,000,000,000 If this concentration can exert an influence on the heart, it is conceivable that the introduction of epinephrine in larger doses, capable of raising the concentration to from 1 5,000,000 to 1 1,000,000 or more, could be decidedly injurious if not extremely dangerous

I am cognizant of reports in the literature indicating that such large doses of epinephrine have sometimes been administered without serious consequences I have often observed this in experimental (anesthetized) animals However, it may be supposed that clinical reports on fatal consequences of overdosage may less likely find their way into the literature Clinicians are familiar with the alarming symptoms often observed following subcutaneous administration of from 5 to 10 minims of 1 1,000 epinephrine as a diagnostic test and we have frequently seen undesirable results of excessive dosage in experimental animals as well as in clinical cases Prominent among the toxic symptoms are sweating, muscle tremors, cardiac palpitation or distress and sometimes collapse It is much safer to rely on epinephrine to produce a response in a small dose, the dose being repeated or increased if necessary, until the desired reaction is obtained

It may appear that undue stress has been placed on the matter of dosage, but it is my conviction that it is not out of proportion to the importance of the subject, since the use of epinephrine has become widespread as a remedy in many branches of the practice of medicine Its use in asthma and other conditions that are related to allergy has been found of great value Here also experienced allergists have observed that effective doses are much smaller than is sometimes supposed to be necessary to obtain the desired effects In serum sickness, angioneurotic edema and urticaria, epinephrine has proved very useful The continued use of epinephrine in asthma has sometimes led to indications of habit formation, but the cases reported are not convincing on this point Supposed addiction, especially following self medication, can probably be better explained as a psychic condition

In hypotension, especially in Addison's disease, administration of epinephrine has not proved beneficial The so-called Muirhead treatment has not proved very effective in any case in which the diagnosis of Addison's disease could not be questioned Indeed, distressing effects from epinephrine, in patients with this disease, is a common observation As the indispensable function of the adrenal is performed by the cortex and not the medulla, it is not surprising that epinephrine is ineffective as a remedy in a disease that is now recognized as due primarily to cortical insufficiency On the other hand, while the cortical hormone is not available in pure form, beneficial effects have been obtained in Addison's disease by oral administration of an extract representing the hormone (interrenalin), made from the adrenal cortex and preserved in glycerin¹⁹ Parenteral administration of cortical extracts thus far has not proved as valuable in this condition as was at first supposed It is possible that the presence of undesirable substances in some such extracts (e g, histamine, choline, protein) may defeat the beneficial action of cortical hormone present in the extracts A pertinent discussion concerning the cortical hormone is given in a recent paper²⁰

It is not possible to review all the therapeutic uses to which epinephrine has been subjected Its value in ophthalmology and in dental surgery is too well known to require comment In this connection may be mentioned the synergistic action of epinephrine when combined with certain other drugs used as local anesthetics Such drugs become more effective either through an influence of epinephrine or because of its local vasoconstrictor effect permitting slower absorption and more prolonged action Mere mention of some of the therapeutic applications of epinephrine will suffice to illustrate its widespread use as a drug It has been employed for relief of internal hemorrhage, but a criticism of this procedure has been suggested in that the sudden elevation of systemic blood pressure, following administration of epinephrine especially in larger doses, may result in aggravation instead of suppression of such hemorrhages In Stokes-Adams syndrome, subcutaneous injection of from 0.3 to 0.6 cc of 1 1,000 solution has been recommended as a safe and effective dose, but intravenous administration may lead to grave reactions²¹ The therapeutic use of epinephrine in angina pectoris has been discouraged by Cottrell and Wood,²² who reported serious consequences following subcutaneous injection of 1 cc of 1 1,000 solution as a diagnostic test in a case The action of epinephrine on the coronary arteries has not been satisfactorily determined There is evidence that it constricts these vessels in man and monkey but dilates those of other animals

A German writer has claimed curative effects from the use of epinephrine in chorea minor, while an American reported negative results It has been used, subcutaneously, to relieve the pain of herpes zoster Improvement or cure of rickets, in children from 1 to 3 years old, by oral administration of epinephrine for from four to six weeks has been claimed, but it should be pointed out that calcium was administered three times daily during this period The use of epinephrine by mouth has been recommended in vertigo on the assumption that it excites the sympathetic nerve endings, regulates the blood pressure and is further "antitoxic" In ocular hypertension, favorable results have been obtained by local application of epinephrine Subcutaneous injection of the drug has been employed for relief and cure of eczema Local injections into hemorrhoids have been stated to be curative Injection of epinephrine fifteen minutes before splenectomy, if the spleen is not sclerotic, is said to reduce chances of excessive hemorrhage because the spleen is rendered bloodless by contraction This effect on the spleen has been utilized as a diagnostic procedure, to distinguish between an enlarged spleen and other tumors Osteomalacia, rodent ulcer, gastric ulcer, psychoses, psychoneuroses, various so-called endocrinopathies and even sea-sickness are among the many conditions for which epinephrine has been recommended In the light of the existing contradictions in the literature, it will not be possible in this article to discuss its use and abuse in so great a variety of diseases At any rate, its alleged benefit in all these conditions is sufficient support for the suggestion that the use of epinephrine in medicine does not represent endocrine therapy in the sense of substituting for lack of function of the adrenal medulla²³

TYPHOID IN THE LARGE CITIES OF
THE UNITED STATES IN 1934

TWENTY-THIRD ANNUAL REPORT

This report deals with the same ninety-three cities that have been discussed in the corresponding articles for the years beginning with 1930. The number of deaths from typhoid during 1934 in each city (except Scranton and Chattanooga, as explained in notes to tables 2 and 5) has been supplied by the respective health department. As the United States Bureau of the Census is convinced that the use of 1933 population estimates in calculating 1934 rates will at least prevent further distortions such as would occur if additional increments were added to population figures that are already too large, the rates in the present article are based on estimates of the population of the cities as of July 1, 1933, made by the Bureau of the Census. This is similar to our procedure of last year, when the 1932 midyear population figures were used to calculate the rates for 1933. It should be pointed out, however, that the 1933 population estimates used here are smaller

* Rate computed from population as of April 1 1930 as no estimate for July 1 1933 was made by the Census Bureau

(with only seven exceptions) than the 1932 estimates formerly furnished us by the Bureau of the Census (see, for example, table 11). This is due to the fact that the bureau has changed its method of estimating city populations. Whereas formerly the method of arithmetical progression was used for each city, the present method is based on the estimated increase in the United States as a whole (figured from birth, death, immigration and emigration figures), distributed to the states according to the percentage that each state's increase between 1920 and 1930 was of the national increase, and the state increase distributed to the counties, and the county increase to the cities.

The problem of including in the rates for each city the typhoid deaths of nonresidents is as conspicuous as it has been for some years. In thirty-one of the ninety-three cities we are informed that one third or more of the typhoid deaths were in nonresidents, in ten of these thirty-one cities all the typhoid deaths were in nonresidents. These are indicated in table 9,

The preceding articles in this series were published in THE JOURNAL May 31 1913 p 1702 May 9 1914 p 1473 April 17 1915 p 1322 April 22 1916 p 1305 March 17 1917 p 845 March 16 1918 p 777 April 5 1919 p 997 March 6 1920 p 845 March 16 1921 p 860 March 25 1922 p 890 March 10 1923 p 691 Feb 2 1924 p 389 March 14 1925 p 813 March 27 1926 p 948 April 9 1927 p 1148 May 19 1928 p 1624 May 18 1929 p 1674 May 17 1930 p 1574 May 9 1931 p 1576 April 30 1932 p 1550 May 13 1933 p 1491 and May 19 1934 p 1677

which should be referred to also in studying tables 1-8.¹ Particulars as to the data that are unavailable for certain cities (noted in tables 2-8 as "incomplete data") are given in the report covering the year 1932 and in the footnotes to these tables in all earlier articles.

Nine of the fourteen large New England cities had no typhoid deaths in 1934 (table 1), and a tenth (Hartford) states that the only typhoid death occurring in 1934 was in a nonresident (table 9). Three cities (Fall River, Lynn and Waterbury) have had no typhoid

deaths for four consecutive years—a remarkable record unequalled heretofore by any of the large cities in this country. Only two cities in the group had 1934 rates of 1.0 or over as against six in 1933, five in 1932 and six in 1931. In the past four years all but three cities (Boston, Hartford and Providence) have had at least one year with no typhoid deaths. Boston has a higher rate (0.9) in 1934 than its noteworthy low mark for 1933 (0.2). The New England cities as a whole have in 1934 the lowest group rate in the country (table

12), this rate (0.53) is a shade better than any previous group rate, the next best being that of the East North Central cities in 1933 (0.55). This is the sixth year of progressive decline in the group rate for the New England cities and the third successive year when the rate has been below 1.0.

The Middle Atlantic cities (table 2) likewise for the past three years have had group rates under 1.0, with a progressive decline (table 12). Seven of the eighteen

1 The problem of the nonresident has been discussed at some length in our previous reports for example J A M A 100 1491 (May 13) 1933 and 98 1550 (April 30) 1932

cities report the complete absence of typhoid deaths during 1934, Elizabeth for the third successive year, Reading, Utica and Yonkers for the second. Elizabeth's record is particularly striking after its high rates in 1930 and 1931 (4.4 and 4.3). Scranton, which had the highest rate of the group in 1933, had no typhoid death in 1934, its only previous clear record having been in 1925. The clear records for Jersey City and Rochester are the first in the histories of these cities. Pittsburgh's 1934 rate (1.5) is ten times higher than its conspicuously low rate for 1933, four of the ten deaths in 1934, however, were stated to be in nonresidents. The present rate is still well below the city's average

for 1926-1930. The three cities besides Pittsburgh with a population of over half a million all had rates under 1.0, New York for the third successive year, Philadelphia and Buffalo for the second. Camden has its lowest rate since 1927.

One of the South Atlantic cities (Tampa) reports no typhoid death in 1934 (table 3). Atlanta continues to show remarkable improvement; its 1934 rate (3.9) being about one third of its rate for 1931 and its average for 1926-1930. For the first time since 1919, Atlanta relinquishes the lowest place in its group and,

† Typhoid deaths for Chattanooga furnished by the Tennessee Department of Health, Nashville

having a rate under 5.0 moves to the second rank among the cities of the country (table 9). Norfolk, which brings up the foot of the list in 1934, used to stand quite consistently at the head but has had relatively high rates for four of the past five years. Baltimore had almost four times as many typhoid deaths in 1934 as in 1933.² The group rate for the South Atlantic cities (2.11) is slightly lower than for the

two preceding years and is less than half of the corresponding rate for 1931 and for 1926-1930, it is better than the best group rate in the country in 1925.

A decided increase in typhoid mortality occurred in the cities of the East North Central group (table 4), with eighty-eight typhoid deaths as against fifty-four in 1933. For the first time in the past five years the

progressive decline of the group rate has been interrupted and, instead of having as usual the best group rate in the country, the East North Central cities in 1934 have fourth place. Even so, their rate is still under 1.0. Only two cities had clear typhoid records in 1934, as against five in 1933, and whereas thirteen of the eighteen cities had rates under 1.0 in 1933 there were only eight with such low rates in 1934. Twelve cities had higher typhoid rates in 1934 than in 1933—slight increases to be sure except in the case of Fort Wayne which after a clear record in 1933, has a rate of 6.7 for 1934. This is the highest rate in the group since

* Incomplete data

1930 and the highest for Fort Worth since 1925. Six of the twelve cities with increases in 1934 state that one third or more of the typhoid deaths were in nonresidents. Detroit in 1934 had eighteen typhoid deaths, nine of them being in nonresidents, six of whom were performers in a traveling circus and had probably contracted the infection in some community which they had visited before coming to Detroit.³ The Chicago increase from 0.3 in 1933 to 0.6 in 1934 is doubtless influenced by the great fire in the Union Stock Yards on May 19, 1934, when people drank water from contaminated sources.⁴

The six East South Central cities (table 5) had exactly the same number of typhoid deaths (sixty-one) in 1934 as in 1933. Only two cities (Knoxville and Nashville) showed decreases in 1934 but these were notably encouraging. Knoxville's rate being the lowest

³ Freund, H. A. Acute Outbreak of Typhoid. J. A. M. A. 103: 622 (Aug. 25) 1934.

⁴ Typhoid Outbreak Among Firemen. J. A. M. A. 103: 116 (July 14) 1934.

² An outbreak of typhoid with twenty-eight cases following a benefit supper was reported in THE JOURNAL, Sept. 1, 1934, p. 686.

in the city's records (which began in 1920) and Nashville's the lowest in its history. Of the increases in the other four cities, that of Chattanooga is conspicuous, being more than double its 1933 rate and about the same as its 1926-1930 average. For the past four years Memphis seems to have assumed the place at the foot of the list formerly occupied by Nashville.

Similarly, in the West North Central cities (table 6) in 1934 there was practically the same typhoid mortality as in 1933 (forty as against forty-one deaths), thirteen of the deaths however, were reported as in nonresidents. Two of the nine cities (St. Paul and Wichita) report no typhoid deaths in 1934 and in two other cities (Omaha and Duluth) all the reported typhoid deaths were stated to be in nonresidents. It is the first clear typhoid year ever recorded for St. Paul but Wichita has had a similar record three times before (1926, 1929, 1931). The only striking change among the cities of this group is the sudden explosion in Des Moines to a 1934 rate of 6.2, its highest rate since 1919.

Like the two preceding groups the West South Central cities (table 7) had practically the same mortality in 1934 as in 1933 (105 typhoid deaths in 1934 and 106 in 1933). Tulsa continues to have the lowest rate in the group, as it has had for every year beginning

TABLE 8—Death Rates of Eleven Cities in Mountain and Pacific States from Typhoid per Hundred Thousand of Population

	1934	1933	1932	1931	1929-1930	1921-1925	1916-1920	1911-1915	1906-1910

* Incomplete data

with 1930, but instead of a clear record such as it had in 1932 and 1933, Tulsa in 1934 has a rate of 2.7. New Orleans continues to have the highest rate in the group, as it has had since 1931, its rate was also the highest in the country in 1931, 1933 and 1934 (table 9). The rate for this group of cities as a whole has been the highest in the country for the past three years.

The cities in the Mountain and Pacific states (table 8) average slightly less for 1934 than for 1933. There are in 1934, as in 1933, two cities without typhoid deaths. Seattle has never had such a record before and Tacoma only once (1928). San Diego's rate, which rose suddenly in 1933, is about two-thirds lower in 1934, though still higher than the 1926-1930 average for that city. Denver while still near the foot of the table, has almost halved its 1933 rate. Spokane, on the other hand, has its highest rate since 1926. San Francisco repeats its 1933 rate of 0.1—a remarkably low rate for a city of more than 500,000 population, equaled only once before by any of the twelve other cities of its size in the country (Pittsburgh in 1933). The nearest approaches in 1934 are Milwaukee (0.2) and Buffalo (0.3).

Of the thirteen cities in the country with more than 500,000 population, eight had 1934 typhoid rates below 1.0, and all thirteen had rates below 2.0, thus appearing in the first rank of table 9. All thirteen appeared together in the first rank for the first time in 1932

and again, with the exception of St. Louis, in 1933. Ten years ago, in 1924, however, only three of these very large cities had rates under 2.0.

In 1934 for the second successive year none of the ninety-three cities registered a typhoid mortality rate greater than 10 per hundred thousand (tables 9 and 10). Twenty-three cities had no typhoid deaths at all

TABLE 9—Death Rates from Typhoid in 1934

Honor Roll				No Typhoid Death (Twenty Three Cities)			
Bridgeport	Elizabeth	Fall River	Grand Rapids	Scranton	Seattle	Somerville	Utica
Jersey City	Lowell	Peoria	Reading	Springfield	Tacoma	Tampa	Waterbury

1933	93	0	7	18	19	33	10
1934	93	0	9	11	27	23	23

had had clear records at least once before, for two (Peoria and Yonkers) 1934 was the seventh year in their history without a typhoid death, while in Waterbury it was the ninth.

Five cities had no death from either typhoid or diphtheria during 1934. Elizabeth, Grand Rapids, New Haven, Seattle, Utica. It is the second successive year that Elizabeth has had a clear record for both diseases.

There are twenty cities in 1934 with rates of 20 and over (table 9, second and third ranks), as against twenty-five in 1933, but in 1934 nine have rates over 50, whereas in 1933 there were only seven with such high rates (table 10). The highest rate for both years is about the same (89 for 1934 and 91 for 1933).

TABLE 11—Total Typhoid Rate for Seventy-Eight Cities, 1910-1934*

	Population	Typhoid Deaths	Typhoid Death Rate per 100 000
1910	22,578,435	4 637	20.54
1911	23,211 941	3 950	17.02
1912	23,835 899	3,182	18.14
1913	24 457,989	3,285	13.43

1915	25 713,846	2,434	9.47
1916	26,257 550	2 191	8.34
1917	26 865 408	2,016	7.50
1918	27 086 696†	1,824‡	6.78
1919	27 735 083†	1,151‡	4.15
1920	28,244,678	1,088	3.85
1921	28,859 062	1,141	3.95
1922	29 478,246	963	3.26
1923	30 087 430	950	3.16
1924	30 701,614	943	3.07
1925	31,815 598	1 070	3.44
1926	31,929 782	907	2.84
1927	32,648 906	648	1.99
1928	33 168 150	628	1.89
1929	33 772,334	537	1.59
1930	34 880 717	554	1.61
1931	35 137 915	563	1.60
1932	35,691,815	442	1.24
1933	35 691,815	423	1.18
1934	35 401 715	413	1.17‡

* The following fifteen cities are omitted from this table because data for the full period are not available: Canton, Ohattanooga, Dallas, Fort Wayne, Jacksonville, Knoxville, Long Beach, Miami, Oklahoma City, South Bend, Tampa, Tulsa, Utica, Wichita, Wilmington.
† Data for Fort Worth lacking.
‡ The rate for the ninety-three cities in 1934 is 1.25 (total population 37 437,512 typhoid deaths 470) whereas the corresponding rates for 1930, 1931, 1932 and 1933 were respectively 1.64, 1.68, 1.34 and 1.24.

Of the twenty cities with 1934 rates of 20 and over, only four are Northern cities (Columbus, Des Moines, Fort Wayne and Spokane). The total of typhoid deaths for the ninety-three cities is exactly the same in 1934 as in 1933 (470), but owing to the new method of estimating the city populations, mentioned earlier in this article, the rate for 1934 appears a shade higher (1.25) than the 1933 rate (1.24). For the seventy-eight cities for which we have complete data since 1910 (table 11), the 1934 total of

TABLE 12—Total Typhoid Death Rate per Hundred Thousand of Population for Ninety-Three Cities According to Geographic Divisions

	(1933) Population	Typhoid Deaths		Typhoid Death Rates						
		1934	1933	1934	1933	1932	1931	1930	1929	1925
New England	2,624 805	14	18	0.53	0.68	0.72	1.07	1.81	2.43	
Middle Atlantic	12,962,300	82	102	0.63	0.78	0.97	1.06	1.40	2.97	
South Atlantic	2,897 807	50	55	2.11	2.31	2.23	4.29	4.50	7.01*	
East North Central	9,643 100	88	64	0.91	0.55	0.70	1.00	1.29†	2.22‡	
East South Central	1 242,600	61	61	4.91	4.91	6.20	4.09	8.31	19.00	
West North Central	2 704 500	40	41	1.48	1.51	1.03	1.34	1.53	3.43	
West South Central	1 934 900	105	106	5.43	5.40	5.20	6.97	7.52‡	18.08§	
Mountain and Pacific	3 968 400	30	33	0.75	0.82	0.57	1.07	1.80	2.53	

* Lacks data for Jacksonville and Miami.
† Data for South Bend for 1925-1929 are not available.
‡ Lacks data for Oklahoma City in 1926.
§ Lacks data for Oklahoma City.

typhoid deaths is ten less than the 1933 total, and the 1934 rate is 1.17, compared to 1.18 in 1933. In four of the eight geographic divisions of the country (table 12) there were fewer typhoid deaths in 1934 than in 1933, and in three other divisions there were either exactly the same number as in 1933 or one

less. The 63 per cent increase in typhoid deaths in the East North Central cities exactly offsets the decreases recorded for the other divisions. Even so, the different divisions have about the same relative typhoid rates in 1934 as in previous years. The cities of four divisions—New England, Middle Atlantic, East North Central and Mountain and Pacific—record very little typhoid, all having had rates below 10 for the past three years and all (except for the 1934 check in the East North Central group) having had a continuous decline in rate during the same period. The West North Central group (table 6) stands alone with consistent rates between 10 and 15. The three Southern groups have their usual order in 1934: South Atlantic (rate 2.11), East South Central (4.91) and West South Central (5.43). The rates of the South Atlantic and West South Central cities have remained about level for the past three years, the level in both groups being well below their rates for 1931 and for 1926-1930. The East South Central group rates, on the other hand, have been higher in the past three years than in 1930 and 1931.

While the total number of typhoid deaths in the ninety-three large cities of the United States was the same in 1934 as in 1933, two points in the 1934 typhoid history are encouraging as to the possibility of further reduction in the urban deaths from this disease: three cities finished their fourth consecutive year without a single typhoid death, and Atlanta, whose rate had continued through 1931 at its 1916-1920 level, has consistently lowered its typhoid mortality by 30 or 35 per cent for each of the past three years.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

SCHOTT'S BUTTER KRUST BREAD SLICED
SCHOTT'S BUTTER KRUST FAMILY LOAF

The Schott's Bakery, Inc., Houston, Texas, submitted to the Committee on Foods a white bread prepared from patent flour, water, sucrose, powdered skim milk, shortening (hydrogenated cottonseed oil), salt, malt extract and a yeast food containing monocalcium phosphate, sodium chloride and potassium bromate, called Schott's Butter Krust Bread and Schott's Butter Krust Family Loaf. The sides of the pans in which the bread is baked are oiled with butter. Other than this, no butter is used. The top crust of the bread is not treated with butter. Approximately 0.02 ounce of butter is added to each pound loaf pan.

Discussion of Name and Label.—The name "Butter Krust" indicates either that the baking formula contains considerable milk-fat or butter or that the entire bread crust has been specially treated with sufficient butter to impart a distinctive butter flavor. Butter, however, is not an ingredient of the bread. Powdered skim milk rather than whole milk is used in the baking formula. The buttered portion of the crust has no characteristic butter flavor. The name implies the entire crust is buttered, which is not the case; gives undue prominence to an ingredient, butter, which is present in insignificant quantity, and is therefore inappropriate, misinformative and misleading. Foods should be truthfully and appropriately named with regard to ingredients.

The manufacturer was given the recommendations and criticisms of the Committee but has not taken action to correct the name. This product will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE OF FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION

RAYMOND HERTWIG Secretary

HEINZ STRAINED APRICOTS

Manufacturer—H J Heinz Company, Pittsburgh

Description—Strained cooked apricots retaining in high degree the natural vitamin and mineral content

Manufacture—Selected ripe unspiced apricots are sorted pitted, trimmed, slightly cooked in steam-jacketed kettles strained in an atmosphere of steam vacuumized to remove air filled into lacquer-lined cans sealed under vacuum and processed. Canned, unsweetened solid pack product may be used instead of fresh fruit, this is heated before being strained, canned and processed as described

Analysis (submitted by manufacturer) —

	per cent
Moisture	84.2
Total solids	15.8
Ash	0.7
Fat (ether extract)	1.0
Protein (N X 6.25)	1.2
Reducing sugars as invert sugar	10.8
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	12.1
Calcium (Ca)	0.02
Phosphorus (P)	0.03
Iron (Fe)	0.002

Calories—0.6 per gram 17 per ounce

Micro Organisms—Bacteriologic and incubation tests show the product to be sterile.

Vitamins—Vitamin biologic assay shows

- 175 Sherman units of vitamin A per ounce
- 4 Sherman units of vitamin B per ounce
- 10 Sherman Bourquin units of vitamin G per ounce

Chemical assay shows

- 45 International units of vitamin C per ounce

Claims of Manufacturer—Specially intended for infants children and convalescents and for special smooth diets. Only warming is required for serving

HAWAIIAN CROSS BRAND HAWAIIAN PINEAPPLE (FANCY QUALITY) SLICED AND TIDBITS

KING OF HAWAII HAWAIIAN PINEAPPLE (FANCY QUALITY) SLICED AND TIDBITS

HAWAIIAN PINEAPPLE TIDBITS (FANCY QUALITY)

FLOWER LAND HAWAIIAN PINEAPPLE—BROKEN SLICES

MOUNTAIN TOP HAWAIIAN PINEAPPLE—BROKEN SLICES

HAWAIIAN STAR HAWAIIAN PINEAPPLE (STANDARD QUALITY) SLICED AND TIDBITS

SURE HIT BRAND HAWAIIAN PINEAPPLE (STANDARD QUALITY) SLICED AND TIDBITS

Distributor—Alexander & Baldwin, Ltd., Honolulu, Hawaii

Packers—Kauai Pineapple Company, Kalaheo, Kauai, Baldwin Packers, Ltd., Lahaina, Maui and the Maui Pineapple Company, Kahului, Maui (subsidiaries)

Description—Grades of sliced and broken sliced pineapple and pineapple tidbits, packed in pineapple juice with added sucrose

Manufacture—Ripe pineapples are peeled and cored, and the ends cut off by "Ginaca" machines. The fruit cylinders produced are trimmed of imperfections, washed and mechanically sliced. The slices are packed by hand in cans and covered with pineapple juice containing added sucrose. The pineapple is graded, according to physical appearance and amount of sugar added to the juice, as "fancy" (the most perfect fruit and the highest concentration of sugar in the juice) "standard"

and "broken slices". The filled cans are heated to about 75 C, are sealed, processed at 88 C and cooled. The broken slices are not as perfect in form as the whole and half slices

ZIMS BETTER WHEAT BREAD

MADE FROM WHITE AND WHOLE WHEAT FLOURS

Manufacturer—The Zim Bread Company, Colorado Springs, Colo

Description—White flour and whole wheat flour bread made by the straight dough method (method described in THE JOURNAL, March 12, 1932, p 889), prepared from water, clear flour, whole wheat flour, sucrose, yeast, shortening, salt, malt syrup, sugar, refiners' syrup and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate

Analysis (submitted by manufacturer) —

VAN CAMPS STERILIZED EVAPORATED MILK

Manufacturer—Van Camp Milk Company, Indianapolis

Description—Sterilized, unsweetened evaporated milk.

Manufacture—Milk is received from state and company inspected farms and is tested daily for odor, acidity and temperature. The milk is preheated to 97-99 C, partially evaporated under vacuum, homogenized, cooled to 38 C, standardized to 7.8 per cent milk fat and 26 per cent total solids content, canned and sterilized at minimum of 116 C. for fifteen minutes

Analysis (submitted by manufacturer) —

SOY BEAN MILK IN INFANT NUTRITION

Although the use of the soy bean for human consumption is comparatively new in this country, it has for many centuries occupied a prominent position in the dietary of the Orient. In China, Japan and Manchukuo the soy bean aids in supplying the population with nitrogenous food. This product is also employed extensively as food in the Philippines, Siam, Korea, the Dutch Indies and India. More recently much interest in the investigation and use of soy bean preparations has been evident throughout the world.¹ The nutritive efficiency of the soy bean was demonstrated by the extensive investigations of Osborne and Mendel.² These results were in striking contrast to those obtained by the same investigators with kidney beans and garden peas. The presence of both the water-soluble and fat-soluble vitamins in the soy bean was also established by the New Haven investigators.

The use of the soy bean, incorporated in a synthetic milk as an infant food, was early studied in the United States by Ruhräh.³ He was able to produce improvement in infants with summer diarrheas and certain forms of intestinal disturbances. Ruhräh also mentioned the value of soy bean milk as a diluent for cow's milk and stated that the product permits normal development in successful feeding. Despite this pioneer work, soy bean milk has not until recent years received serious consideration in this country as a definite food for babies. This vegetable milk has been employed quite extensively in China, as economic stress and the relatively small consumption of dairy products in China are important factors in the promotion of the soy bean as a food substitute for cow's milk. The studies of Chang and Tso⁴ at Peiping University have served to stimulate interest in the use of the soy bean in infant feeding. The Chinese investigators prepared a synthetic vegetable milk the proteins of which were sup-

plied by the soy bean. Six infants, one from birth and the others a few weeks old, were successfully fed for from six to nine months on this diet. Their weight curves followed closely the average weight curves of healthy nursing infants in the United States as well as the average weights of several hundred Chinese breast-fed infants who visited the college dispensary for minor complaints.

Recent reports of the use of soy bean milk in this country have substantiated the value of this product in infant feeding. Although the synthetic preparations used have differed somewhat in their formulas, the results have been uniformly favorable. Thus Rittinger and Dembo⁵ fed soy bean milk to fifty physically normal or average infants over a period of a year. The progress in weight and state of nutrition indicated that the soy bean, with the addition of sugars and various mineral salts, can be made an adequate food for infants. The stool was somewhat more bulky than that observed in infants fed cow's milk, but the flora resembled that of the normal, breast-fed baby. Supplementary experiments by these investigators, conducted with rats, demonstrated the presence of adequate amounts of necessary vitamins in the preparation employed.

The economic features (mass production and low cost) of soy bean milk as an infant food share importance with the utilization of this material for the feeding of infants with milk idiosyncrasy. Furthermore, it is evident that the development of a food, free from milk protein which is capable of maintaining infant nutrition, should furnish definite proof of the allergic nature of infant eczema. Studies of this question have been conducted in the department of pediatrics of the Harvard Medical School.⁶ Experimenting with powders of varying composition, the Boston investigators evolved a dried preparation in which the protein was furnished by the soy bean and which on reliquefaction constituted a milk well tolerated by the digestive tract of infants and capable of maintaining their nutrition. Although the results were not favorable in every case, this method of feeding allergic infants has helped in a large enough number of cases to recommend it as worthy of trial. Further laboratory data are accumulating to support the early evidence concerning the adequacy of soy bean flour in nutrition. Stearns⁷ has recently investigated the relation of the intakes of nitrogen, calcium and phosphorus on the excretion and retention of these elements by infants on milk diets in comparison to the results obtained with the same infants given soy bean feedings. The detailed analytic reports indicate that the modified soy bean food appears to be a satisfactory product for infants. Other experiments

on laboratory animals * have demonstrated the adequacy of soy bean powders in nutrition particularly with respect to supporting normal growth hemoglobin formation and the production of normal bones. There appears to be considerable evidence, therefore, to warrant the conclusion that the soy bean is destined to assume a role of importance in infant nutrition.

REFORM IN RADIO ADVERTISING

At last these United States seem to be en route to reform in the type of advertising promoted over the radio. For some time the National Broadcasting Company has been quietly and consistently elevating the standards of material permitted to be broadcast over its network. The Columbia Broadcasting System has just made available an announcement by its president setting forth the new policies which will guide that network for the future.

Briefly the new policies involve purification in the type of material broadcast to children both as entertainment and as advertising. The Columbia Broadcasting System will not permit broadcasting for any product that describes graphically or repellently any internal functions, symptomatic results of internal disturbances or matters that are generally not considered acceptable in social groups. This policy will specifically exclude from advertising not only all laxatives as such but the advertising of any laxative properties in any other product. It will further exclude the discussion of depilatories, deodorants and other broadcasting which by its nature represents questions of good taste in connection with radio listening. Among other basic advertising policies will be the barring of testimonials that cannot be authenticated and an attempt to bar claims that are false and unwarranted.

This new trend in the control of radio advertising must logically be associated with several evidences of endeavors by the government to control in various ways the evil of exaggerated and fraudulent advertising which has been gradually pyramided during the last thirty years into a structure that would inevitably sooner or later have toppled of its own weight. Among the handwritings on the wall are the passage by the Senate of the new Copeland bill, which, though utterly inadequate, is nevertheless a beginning in the direction of legislation to control advertising, and also hearings recently held by the Federal Communications Commission on the subject of education by radio.

The House of Delegates of the American Medical Association at its sessions in 1933 and again in 1934 adopted resolutions opposing misleading radio broadcasting. In pursuance of this action of the House of Delegates, two representatives of the headquarters office of the American Medical Association appeared before the hearings conducted by the Federal Communications Commission in Washington on May 15

Dr. W. W. Bauer, director of the Bureau of Health and Public Instruction, emphasized the interest of the American Medical Association in proper education in the field of health and indicated the manner in which radio education is involved in its program. He also recounted some of the experiences of the medical profession in attempting to secure adequate broadcasting in the field of health not only over the national chains but also over various local outlets. Dr. Arthur J. Cramp, director of the Bureau of Investigation, presented a statement with respect to 'patent medicine' advertising on the radio, supplementing his presentation with typewritten copies of phonographic records that had been made of five "patent medicine" announcements. His statement covered particularly broadcasts recently made for Peruna Willard's Tablets, Ex-Lax, Alka-Seltzer and Crazy Crystals, and he provided the Federal Communications Commission with details regarding these 'patent medicines'.

Great nations move slowly in their efforts for reform, but eventually an annoyed and deceived but too tolerant public rises in its wrath and reacts against those who abuse its tolerance.

THE EFFICIENCY OF SERODIAGNOSTIC TESTS FOR SYPHILIS

The report of the committee on the evaluation of serodiagnostic tests for syphilis in the United States appears in this issue of *THE JOURNAL*.¹ Facts pertaining to the serologic tests or modifications of such tests as have been described in the United States are given in detail. The committee has avoided entirely any comment on the method of any one serologist. The relative efficiency of the several tests is evident, however, if one cares to analyze the report. The study was comprehensive and the results are comparable with those attained in the conferences held some years ago under the auspices of the League of Nations in Copenhagen and Montevideo.

In the actual performance of the tests, the participating serologists were not gathered in one place to examine specimens over a short period of time. The advantage was given them of performing these examinations in their own laboratories. The evaluation study in this country differed from the former conferences also in the selection of presumably nonsyphilitic donors. In Copenhagen and Montevideo, such donors were selected from general hospital patients who were believed not to be infected with syphilis. In the evaluation study as conducted in this country, the nonsyphilitic donors were made up of a specially selected group in which there was reason to believe that the incidence of syphilis would be considerably lower than in a general hospital population.

* Reid E. *Chinese J. Physiol.* 9:27, 1935.

¹ Cumming H. S., Hazen H. H., Sanford A. H., Sencar F. E., Simpson W. M., and Vonderlehr, R. A. The Evaluation of Serodiagnostic Tests for Syphilis in the United States, this issue, p. 2083.

Of much interest is the relative efficiency of flocculation tests as compared with complement fixation tests for syphilis. Generally speaking, the former compared most favorably with the more complex serologic procedures both in specificity and in sensitivity. This was true especially when such tests were applied in the examination of blood serum. It was not true to the same extent, however, when the application was made to spinal fluid. The variation in specificity and in sensitivity from the highest to the lowest percentage was more definite in the spinal fluid examinations than in the blood specimens, and the percentage of positive reports in known neurosyphilitic spinal fluids was low in the case of several of the flocculation procedures. This indicates that the flocculation tests for spinal fluid examination should be given further study.

One of the most interesting conclusions of the evaluation committee is that a highly sensitive flocculation test alone might be employed as a routine procedure to exclude syphilis. The evidence available indicates that when such a test is employed a negative result would practically eliminate the presence of syphilis as demonstrable by any other serologic method. However, because of the highly sensitive character of the flocculation procedure a positive test would not be indisputable evidence of syphilitic infection. A further recommendation therefore is made that, when a positive result is reported with the routine highly sensitive flocculation test, the serum should be reexamined by one or more specific complement fixation or flocculation tests. The majority of serologic tests for syphilis performed in the laboratories of the country are negative. The routine adoption of such a highly sensitive flocculation test in comparison with the routine performance of a combination of two or more serologic tests would be an important factor in reducing the cost of the serodiagnosis of syphilis. Such a method of serologic testing seems to be worth a trial and may offer a solution for the present high cost of this work in laboratories.

Information was not obtained with regard to the practical application of the individual serologic procedures as employed in laboratories throughout the country, nor is a specific statement made with regard to the cost of the several procedures evaluated. Such factors are of the utmost importance, especially the practical application of serologic tests in private and public health laboratories.

The recommendation was made that the reporting of the qualitative results in the serodiagnosis of syphilis be simplified. A similar recommendation was made by the League of Nations after the Copenhagen conference. The adoption of a different set of symbols to express the degree of positivity by every serologist who describes a new method or modification has been most confusing to the physician in the past. The committee is to be commended for its insistence on a simplified method of reporting in which all qualitative results are reported as positive, doubtful or negative.

Current Comment

THE MONUMENT FOR JANE TODD CRAWFORD

Memorial Day for 1935 was marked by an unusual feature from the point of view of the medical profession. In Danville, Ky., the Kentucky State Medical Association dedicated a monument to the memory of Jane Todd Crawford, who, 126 years ago, voluntarily submitted herself to the first ovariectomy. This monument is perhaps the second ever dedicated anywhere in the world to a heroic patient, the first being that of Jean Baptiste Jupille, the shepherd boy who fifty years ago was given the Pasteur treatment after he had courageously fought a mad dog and saved the lives of six children. Already a monument stands for Ephraim McDowell, the noted physician who performed the operation on Mrs. Crawford. Today his name is high among those who have contributed largely to the advancement of abdominal surgery. At a time when anesthesia and asepsis were as yet unknown, these two—Ephraim McDowell and Jane Todd Crawford—wrote large their names in the history of medicine. Today, through the advancement of medical science, it is possible to perform the most difficult operations almost anywhere in the world. In 1809 such an operation involved on the part of the surgeon the sureness of scientific skill, the courage of his convictions, and the willingness to hazard personal reputation for the life and health of his patient, for the patient, the ability to bear inexpressible agony, the courage to risk an unestablished medical procedure, and a comprehension of the hazards involved. It is well that monuments should stand side by side to both physician and patient who cooperated in this memorable action and that the medical profession of the state of Kentucky should have assumed the responsibility for the erection and dedication of these two memorials.

BACTERIA IN KANSAS DUST

The recent dust storms in certain districts of the western part of the United States have been accompanied apparently by unusual numbers of cases of "dust pneumonia." Such a coincidence might well excite interest in the comparative numbers and types of bacteria in the air during a dust storm as compared with those present on an average quiet day. A study of this type has been reported recently.¹ Petri dishes containing sterile nutrient agar culture mediums were exposed for varying periods during a severe dust storm. The plates were incubated for twenty-four hours and the colonies then counted. Control plates were exposed in a similar manner on a clear, calm day. A striking difference between the numbers of colonies on the two plates was found. The plates exposed for one minute on a calm day contained only twelve colonies, whereas those exposed for only half this time during a dust storm showed 1,100 bacterial colonies. Microscopic

¹ Rutter, C. Bacterial Content of the Kansas Dust Storm on March 20, 1935. Pub. Health Rep. 50:622 (May 3) 1935.

examinations of a number of the colonies from the latter plates have indicated that the organisms carried by the dust were largely resistant soil types, usually large, spore-forming, gram-positive bacilli. No coccus forms were found. The latter observation may be of particular importance for, unless the presence of increased numbers of pathogenic bacteria can be established, there is no reason to associate the occurrence of "dust pneumonia" with a mere increase in the number of bacteria in the air. The effect of the dust may be entirely mechanical, inducing changes in the mucous membrane of the trachea and bronchi, which permit the passage of pathogenic organisms usually present in the upper respiratory tract to the bronchi and lungs.

REREGISTRATION UNDER THE HARRISON NARCOTIC ACT

Physicians registered under the Harrison Narcotic Act must reregister on or before July 1. Each such physician must register with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients. Failure to register within the time allowed by law makes a physician liable to a fine or to imprisonment, or to both, and compels him to pay a penalty of 25 per cent on his annual tax when he does register.

Association News

THE ATLANTIC CITY SESSION

Fraternity and Club Dinners

The Ohio State Medical Alumni will hold their dinner at the Ambassador Hotel, Atlantic City, June 12, 6:30 p. m.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Chicago daylight saving time (3:30 central standard time). The next three broadcasts will be as follows:

- June 13 Summer Camps C. C. Bean
- June 20 Burns W. W. Bauer, M.D.
- June 27 Blood and Fire W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15 Chicago daylight saving time (3 o'clock central standard time). The next three broadcasts will be as follows:

- June 11 See announcement of broadcasts from annual session
- June 18 Only One Pair of Eyes W. W. Bauer, M.D.
- June 25 The Nation's Birthday, W. W. Bauer, M.D.

Radio Broadcasts from Atlantic City and Philadelphia

Through the courtesy of the National Broadcasting Company and the Columbia Broadcasting System, the American Medical Association will broadcast health talks to the public in connection with the annual meeting at Atlantic City, June 10 to 14.

The talks over a network of the National Broadcasting Company will originate in the studios of Station WFIL at Phila-

delphia, according to the following schedule (eastern daylight saving time):

- June 11, 5-5:15 p. m. The Polio Situation by Dr. J. P. Leake
- June 13, 6-6:15 p. m. News Features from the Convention, W. W. Bauer, M.D.
- June 14, 5-5:30 p. m. Medicine in North America
- Nutrition and the Health of the Race by Dr. James S. McLester
- Truth in Therapeutics, by Dr. Jonathan C. Wenkins
- Speakers to be introduced by Dr. Morris Fishbein

The talks over a network of the Columbia Broadcasting System will originate in the studios of Station WPG, Atlantic City, according to the following schedule:

- June 10, 5-5:15 p. m. Sidelights on Sleep by Dr. Glenville Giddings, Jr.
- June 14, 3:15-3:30 p. m. Problems of the Hard of Hearing by Dr. Austin A. Hayden

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bills Introduced—H. 496, seeking to amend the workmen's compensation act, among other things, proposes to require an employer to furnish medical and surgical treatment to a worker disabled in an industrial accident during the first ninety days (rather than sixty days) of disability and to raise the employer's liability for such services to \$300, rather than \$100, as the present law provides. H. 479, to amend the workmen's compensation act, proposes to require an employer to furnish medical and surgical treatment to a worker disabled in an industrial accident, during the first four months of disability, and to raise the employer's liability for such services to \$300. H. 448 proposes to create a board of chiropody examiners and to regulate the practice of chiropody, which the bill defines as the medical, surgical, electrical, mechanical and manipulative treatment of ailments of the human foot.

ARKANSAS

District Meetings—The Third Councilor District Medical Society was addressed at DeValls Bluff, April 5, among others by Dr. Eugene M. Holder, Memphis, on acute surgical conditions of the abdomen. Speakers before the Fifth Councilor District Medical Society at Magnolia, April 9, included Dr. Royal J. Calcote, Little Rock, on "Corneal Ulcer"; Dr. Ray M. Balyeat, Oklahoma City, addressed the Fourth Councilor District Medical Society in joint session with the Jefferson County Medical Society at Pine Bluff in April on asthma. At a joint meeting of the Second Councilor District Medical Society with the woman's auxiliary at Batesville, April 8, speakers were Drs. Silas C. Fulmer, Little Rock, on "Diagnosis of Heart Failure"; Ernest H. White, Little Rock, "Prophylaxis of Pyelitis of Pregnancy"; and Frederick H. Krock, Fort Smith, "Occlusive Arterial Disease of the Extremities." Speakers before the First Councilor District Medical Society of Arkansas, May 8, in Monette, included Drs. Jones H. Lamb, Paragould, on "Pericious Anemia"; William C. Colbert, Memphis, "Systemic Manifestations of Focal Sepsis"; Elmer H. Rainwater, Walnut Ridge, "How to Treat Rectal Patients"; William W. Walker, Memphis, "Obstetrical Complications of the Last Trimester of Pregnancy"; Herbert Fay H. Jones, Little Rock, "Urologic Backache"; and Herbert H. McAdams, Jonesboro, "Surgical Management of Gout."

CALIFORNIA

Personal—The twentieth anniversary of Dr. John L. Pomeroy as the first full time county health officer of Los Angeles was observed with a dinner dance at the Oakmont Country Club in Montrose, April 25.

Regulations on Cream Custard Fillings—At a meeting of the California State Board of Public Health, April 20, a resolution was adopted that will increase the protection of the public against food poisoning from contaminated cream custard fillings. According to the new regulations, only efficiently pasteurized milk may be used. The temperature and time of

heating the mixture shall be, as a minimum, the equivalent of a temperature of 140 F for one hour, provided however that other temperatures and times may be used when specifically approved by the director of public health. When finished cooking, the custard must be immediately transferred into previously sterilized containers, properly covered, and chilled without delay to 50 F, and must be kept in a cooling room until used in making pastries. The resolution further regulates the display of these products, the cleansing of the cooking apparatus and the selling and delivery. In the resolution, the board acknowledges that poisoning with the toxins of staphylococci present in foods is becoming more common.

CONNECTICUT

Society News—Dr Nathan B Van Etten New York, addressed the Hartford County Medical Association, Hartford April 2, on medical economics.

Bills Enacted—The following bills have become laws. H 1264, to permit chiropractors to render the "medical treatment" which an employer must furnish a workman injured in the course of his employment, and H 1270, amending the chiropractic practice act so as to require the secretary-treasurer of the board of chiropractor examiners to furnish a bond in the sum of \$1,000 with such sureties as are acceptable to the state treasurer.

DISTRICT OF COLUMBIA

Medical Bills in Congress—S 2939, introduced by Senator Copeland, New York, proposes to require the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to practice the healing art in the District of Columbia to Dr Ronald A Cox, Washington, without examination.

University News—Karl F Meyer, Ph D, director of the Hooper Foundation and professor of bacteriology, University of California Medical School, San Francisco, gave the sixth and last lecture of the Smith-Reed-Russell series for this year at George Washington University School of Medicine, May 14. He spoke on "Selvatic Plague," with illustrations. In the afternoon Dr Meyer addressed the medical faculty and guests on psittacosis. Col Percy M Ashburn, superintendent of Columbia Hospital, Washington, gave the fifth lecture in the series, April 25, on "The Medical History of the Conquest of America in the Sixteenth and Seventeenth Centuries."

FLORIDA

Bill Enacted—H 29 has become a law, providing for a system of compensating workmen for injuries arising out of and in the course of their employments and for such diseases or infections as naturally or unavoidably result from such industrial injuries. The employer is to furnish medical, surgical and other remedial treatment, nursing and hospital service, medicines, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. Only in the event that the employer fails to furnish the services, after request by the workman, is the workman to be allowed the privilege of selecting his own physician at the employer's expense.

ILLINOIS

State Medical Election—Dr Rolland L Green, Peoria, was chosen president-elect of the Illinois State Medical Society at its annual meeting in Rockford, May 23, and Dr Charles B Reed, Chicago, was installed as president. Vice presidents elected are Drs Thomas H Culhane, Rockford, and Fred H Muller, Chicago. Dr Harold M Camp Monmouth, was reelected secretary for the twelfth time and Dr A J Markley, Belvidere, treasurer for his twenty-third term.

Bill Introduced—S 515, to amend the laws regulating the practice of medicine, proposes to enumerate specific causes for which the department of registration and education may revoke or suspend licenses and to designate the procedure to be followed by the department in revoking or suspending licenses. This bill is apparently designed to obviate certain constitutional objections to the present Illinois medical practice act pointed out in *Schireson v Walsh* 187 N E 921 THE JOURNAL, Aug 4, 1934, p 367.

Chicago

Personal—Dr Ludvig Hektoen, director of the John McCormick Institute for Infectious Diseases and chairman of the Committee on Scientific Research of the American Medical Association has been appointed a member of the board of trustees of Science Service, representing the National Research Council.

Society News—Speakers before the Chicago Society of Internal Medicine, May 27, included Dr Anton J Carlson on "The Problem of Control of the Endocrine Glands"—Dr Edward W Alton Ochsner, professor of surgery, Tulane University of Louisiana School of Medicine, New Orleans, gave the sixth annual Stephen Walter Ranson Lecture, sponsored by Theta chapter of Phi Beta Pi Fraternity, May 31, at North western University Medical School, his subject was "Postoperative Treatment Based on Physiological Principles."

Dr Grinker to Head New Department—Dr Roy R. Grinker, associate professor of neurology, Graduate School of Medicine, Division of Biological Sciences, University of Chicago, will be in charge of the new department of psychiatry, the establishment of which was recently made possible by a grant of \$168,000 from the Rockefeller Foundation (THE JOURNAL, May 25, p 1914). Dr Grinker will return to the university, July 1, after two years abroad spent in research and study in psychiatry under a fellowship from the foundation. Research into the causes and cure of mental diseases will be carried on in the new division, which will be organized within the department of medicine. It will be opened July 1.

IOWA

Conference on Child Development—The ninth annual Iowa Conference on Child Development and Parent Education will be held in Iowa City, June 17-19. The health of the young child will be the theme of the lectures and round tables of the meeting, which is held in conjunction with the eighth health education conference of the American Child Health Association in Iowa City, June 19-22. In addition to members of the faculty of State University of Iowa College of Medicine, the following will participate:

Dr Frederick H Allen director child guidance clinic Philadelphia
Vivian T Thayer educational director of the Ethical Culture School, New York

Miriam Van Waters superintendent, Reformatory for Women Framingham Mass

Charles Edward A Winslow, Dr P.H professor of public health, Yale University School of Medicine, New Haven Conn

John E Anderson Ph D director Institute of Child Welfare University of Minnesota Minneapolis

Dr Joseph H Kinnaman director child health and health education Iowa State Department of Health Des Moines

LOUISIANA

Personal—Dr Amédée Granger, New Orleans, received the honorary degree of doctor of science at the diamond jubilee celebration of Tulane University recently.

State Medical Election—Dr Hiram W Kostmayer, New Orleans, was chosen president-elect of the Louisiana State Medical Society at its annual meeting in New Orleans, April 29-May 1. Dr Courtland P Gray, Monroe, was installed as president and the following vice presidents were elected: Drs Louis B Long, Lafayette, Henry L. Gardner, Crowley, and Rhett G McMahon, Baton Rouge. The next annual session of the association will be held in Lake Charles.

MAINE

State Medical Meeting at York Harbor, June 23-25—The eighty-third annual session of the Maine Medical Association will be held at York Harbor, June 23-25, with headquarters at the Marshall House. The morning sessions will be given over to round table conferences, while at the afternoon sessions the following program will be presented:

Dr Edward H Risley Waterville Acute Pancreatitis

Dr Thomas A Foster Portland The Tonsil Problem.

Dr Harold M Goodwin Bangor Modern Treatment of Pelvic Inflammation

Dr Harry Archibald Nissen Boston Significance of the Life Course, or Level of Functional Activity of the Arthritic A Study Based on Comparison of a Hundred Dead and Four Hundred Living

Dr William Holt Portland, Radium Therapy for Carcinoma of the Uterus

Drs Harris P Mosher and Alexander S MacMullan Boston The Esophagus from a Clinical and Roentgenologic Viewpoint.

Dr Charles B Popplestone, Rockland The Role of the Pituitary Gland in Endocrine Dysfunction

Drs Eugene H Drake, Richard S Hawkes and Mortimer Warren all of Portland Maine's First Epidemic of Trichinosis

At this meeting, fifty year service medals will be presented to the following eligible physicians: Edward S Abbott, Bridgton, George F Bates, Yarmouth, Herbert J Patterson, Portland, J Frederick Hill Waterville, and Horace J Binford, Mexico. These medals will be presented at the annual banquet, Tuesday evening, when the principal speaker will be Dr Walter L Biering Des Moines, President, American Medical Association his subject will be "American Medical Association and Plans for Economic Security."

MASSACHUSETTS

Celebration in Honor of Dr Morse—The seventieth birthday of Dr John Loyett Morse, professor emeritus of pediatrics, Harvard Medical School, Boston, was observed at a dinner, April 22, given by former house officers and pupils. A charcoal portrait of Dr Morse was presented to him, the artist was Mr Dwight Shepler. Dr Richard M Smith was toastmaster.

Society News—Dr John H Stokes, Philadelphia, addressed the annual meeting of the Massachusetts Society for Mental Hygiene, April 23, on "The Doctor, the Public and the Syphilis Problem."—Dr Elliott C Cutler Moseley, professor of surgery, Harvard University Medical School, Boston, was elected president of the Associated Harvard Clubs at its annual meeting recently.

Bill Introduced—H 2147 to supplement the workmen's compensation act, proposes that whenever an employee claims compensation for an industrial disease his claim is to be submitted by the industrial accident board to three referees, selected by the board from a list, submitted by the board of registration in medicine, of licensed physicians skilled in the diagnosis and treatment of industrial diseases. After investigation, the referees are to report their findings of medical fact to the industrial accident board.

Dr Rosenau to Retire—The retirement this year of Dr Milton J Rosenau, since 1909 Charles Wilder professor of preventive medicine and hygiene has been announced. Aged 66, Dr Rosenau graduated from the University of Pennsylvania School of Medicine in 1889 and pursued graduate work at the Institute of Hygiene Berlin, Pasteur Institute, Paris, and Institute of Pathology, Vienna. He was a surgeon in the U S Public Health and Marine Hospital Service from 1890 to 1909, and director of the hygienic laboratory of the Marine Hospital from 1899 to 1909. In that year he was named professor of preventive medicine at Harvard and in 1922 was made professor of epidemiology in the Harvard School of Public Health. A portrait of Dr Rosenau was presented to the medical school, May 14, by a committee of Dr Rosenau's colleagues, including Drs Elliott P Joslin, Boston, chairman, Harvey Cushing, New Haven, Conn., Henry D Chadwick, Newton, Reid Hunt, Boston, Samuel C Prescott, Brookline, Edwin B Wilson, Boston, G Smillic, Boston, Joseph W Schereschewsky, Boston, and Lloyd D Felton. The work of Jacob Binder, Boston, the portrait will be hung in the faculty room of the administration building of the school.

MICHIGAN

University News—The Sternberg Memorial Medal has been awarded by the executive faculty of the University of Michigan Medical School to William George Gordon, this is an annual prize given to the medical student who has the best record in preventive medicine. The Wee Kim Lim scholastic key was awarded to student Robert Toru Masuhara for his work in roentgenology. This key was established by the Michigan Alpha chapter of Alpha Lambda, the international Chinese fraternity, to be presented to a distinguished senior medical student each year.

Society News—Dr Thomas K. Gruber, Eloise, was chosen president-elect of the Wayne County Medical Society at its annual meeting in Detroit, May 20. Dr Robert C Jamieson, Detroit, was installed as president. Dr Martin H Hoffmann, Detroit, was elected secretary. Dr Arthur T McCormack, Louisville, secretary, Kentucky State Medical Association, discussed "Medical Service in a Changing World" at this meeting. The society was addressed by Dr Douglas W Owen at its meeting, April 15, his subject was "Vienna, the Mecca of Medicine in the Europe of Today." At a recent meeting the society adopted a resolution commending the action of the House of Delegates of the American Medical Association at the special session in Chicago, February 15-16. The resolution was introduced by Drs Henry A Luce and John R Boland, Detroit.—Dr George C Burr, Detroit, discussed common urinary infections before the Livingston County Medical Society, May 3.—Dr Wingate Todd addressed the Detroit Pediatric Society, May 6, on "X-Ray Studies of Mineralization in Children."—At a meeting of the Bay County Medical Society in Bay City May 15, Dr Walter J Wilson, Detroit, spoke on "Low Blood Pressure."—Dr Clarence H Crego Jr., St. Louis, discussed "The Operative Correction of Lower Extremity Length Inequality" at the Grace Hospital, Detroit, May 10.—Dr George S Bond, Indianapolis, discussed "Hypertension and Coronary Artery Diseases" before the Calhoun County Medical Society in Battle Creek, May 7.

MISSOURI

State Medical Election—Dr Edwin Lee Miller, Kansas City, was inducted into the presidency of the Missouri State Medical Association at its annual meeting in Excelsior Springs, May 8, and Dr Ross A Woolsey, St. Louis, was chosen president-elect. The next annual session will be held at Columbia in 1936.

Society News—The woman's auxiliary to the St. Louis County Medical Society sponsored a public relations program, March 29. Drs Hymian I Spector, assistant health commissioner, and Richard S Weiss, assistant professor of clinical dermatology, Washington University School of Medicine, discussed tuberculosis and cancer, respectively. Also a motion picture on malaria was shown.—Dr Grandison D Royston, St. Louis, discussed "Trauma During Labor" before the Cape Girardeau County Medical Society, April 8.—Speakers before the Cass County Medical Society in Harrisonville, March 14, included Dr Lotus V Murray, Pleasant Hill on "Carcinoma of the Cervix."—The Greene County Medical Society was addressed, March 22, by Drs Frank R Teachener, Kansas City, and Meyer Wiener, St. Louis, on "Brain Injury" and "Plastic Surgery of the Eye," respectively.—At a meeting of the Pettis County Medical Society in Sedalia, March 18, Drs Leroy A Calkins, Kansas City, and Harold L Garney, Kansas City, Kan., spoke on "Treatment of Menorrhagia" and "Use and Abuse of Cesarean Section," respectively.

NEBRASKA

Bill Enacted—H 587 has become a law, prohibiting the retail distribution or sale of barbital, sulphoethylmethane (Trional), sulphonmethane (Sulphonil), diethylsulphon diethylmethane (Tetronal), carbonal, paraldehyde and chloral or chloral hydrate or chlorbutanol, except on the prescription of a licensed physician, dentist or veterinarian.

NEW JERSEY

State Medical Election—Dr Francis R Haussling, Newark, was chosen president-elect of the Medical Society of New Jersey at its annual meeting in Atlantic City, May 2. Dr Marcus W Newcomb, Browns Mills, was inducted into the presidency of the association and Drs Spencer T Snedecor, Hackensack, and William G Herrman, Asbury Park, were elected vice presidents.

NEW YORK

State Medical Election—Dr Floyd S Winslow, Rochester, was chosen president-elect of the Medical Society of the State of New York and Dr Frederic E Sondern, New York, installed as president, at the annual meeting, May 14. Dr Daniel S Dougherty, New York, was reelected secretary. The next annual meeting will be held in New York.

New York City

Death from Radium Poisoning—A young woman died of radium poisoning, March 18, after several years' illness, according to the New York Times. She had worked for six years in several plants painting luminous faces of watches and clocks with a brush, pointed by wetting on the lips and tongue.

Hospitals Report Increased Costs—Twenty-four general and special Catholic hospitals in New York with a bed capacity of 4,178, reported a total operating cost of \$3,605,176 in 1934, an increase over 1933 of \$249,036. They gave 350,000 days of free care to more than 12,000 patients at a cost of \$1,759,530. Inpatients during the year numbered 54,650, of whom only 32 per cent paid regular hospital rates. The city paid for about a third, a little more than 14 per cent paid something and 21 per cent paid nothing, it was said. Seven hospitals operated clinics in which 39,459 were treated, an increase of almost 2,000 over 1933. The hospitals had an operating deficit of \$188,681.

Data on Health Center Plan—The New York City Department of Health recently published a "Handbook of Statistical Reference Data," prepared by the committee on neighborhood health development. It contains information concerning the seven health center districts already established under the newly created bureau of district health administration, with information on population and causes of sickness and death in all the thirty districts that will be eventually included in the plan. The statistics are selected and arranged by districts in order to allow the health administration to plan for the special problems of each. Such information as nationality, rentals of homes, birth rates, infant and maternal mortality and facts that have a bearing on the type of health program needed are included.

Personal—The Richmond County Medical Society gave a dinner in honor of Dr. Walker Washington, Staten Island, April 9, celebrating his fiftieth anniversary in the practice of medicine. Dr. Washington, a native of Virginia, now 74 years old, is president of the Tottenville National Bank.—Dr. Victor Mildenberg, director of the bureau of preventable diseases, New York City Department of Health, was guest of honor at a banquet recently at the Hotel Granada, marking thirty years of service with the department. Speakers were Drs. Robert Olesen of the U. S. Public Health Service and John H. R. Barry.—Dr. John L. Rice, health commissioner, has been designated official representative of the American Public Health Association to the congress of the Royal Sanitary Institute of England, to be held in Bournemouth, July 15-20.

NORTH CAROLINA

Society News—Drs. Charles R. Bugg and Adlai S. Oliver, Raleigh, addressed the Wake County Medical Society, March 12, on "Unusual Pneumonias in Children" and "Chronic Cervicitis," respectively.—Speakers at a meeting of the Iredell-Alexander Counties Medical Society, Taylorsville, March 12, were Drs. James W. Davis, Statesville, on "Surgery of the Prostate," Joseph S. Holbrook, "The Electrocardiogram in Cardiovascular Disease," and Milton B. Clayton, "Eye Findings Associated with Cardiovascular Disease"—Dr. Laurence J. Rhea, Montreal, addressed the Buncombe County Medical Society, April 1, on "Development and Course of Peptic Ulcer"—Dr. John S. Lundy, Rochester, Minn., addressed the Forsyth County Medical Society, Winston-Salem, March 6, on anesthesia.—Dr. Francis Bayard Carter, Durham, gave a paper on "Nonconvulsive Toxemias of Pregnancy" before the Eighth District Medical Society at Asheboro, April 9.

OHIO

Physician Honored—Dr. Benjamin S. Kline, Cleveland, received the 1935 Charles Eisenman Award of the Jewish Welfare Federation of Cleveland, March 31, in recognition of his contributions to medical science. Dr. Kline immediately presented the award, a check for \$1,000, to Mount Sinai Hospital, where he is director of laboratories, for further research. Among contributions cited were Dr. Kline's research on pneumonia and discovery of a precipitation test for diagnosis and exclusion of syphilis. Dr. Kline is assistant professor of pathology at Western Reserve University School of Medicine.

Fifth District Annual Meeting—The fifth district of the Ohio State Medical Association held its annual meeting in Cleveland at the Allen Memorial Medical Library, May 17. Dr. Francis M. Rackemann, Boston, addressed an evening session combined with a meeting of the Academy of Medicine of Cleveland, on "The Role of Allergy in General Medicine." Among speakers at the day sessions were the following Cleveland physicians:

Dr. Vernon C. Rowland, Treatment of the Chronic Dyspeptic
Dr. Russell L. Haden, Agranulocytosis: Its Prevention and Treatment
Dr. James L. Reycraft, Management of Hypertension
Dr. Robert S. Dinsmore, Jr., Management of Peritonitis
Dr. Abraham Strauss, Treatment of Cancer of the Breast.

PENNSYLVANIA

Memorial to Woman Physician Proposed—The class of 1918 at Bryn Mawr College, Bryn Mawr, plans to raise \$50,000 to establish a library of chemistry and physics in a new science building at the college as a memorial to the late Dr. Marjorie Sharps Jefferies Wagoner, a member of the class. Dr. Wagoner was the college physician for twelve years. She died, June 22, 1934.

Bills Passed—H. 2742 has passed the house, proposing to prohibit the sale of barbital, sulphonethylmethane (trional), sulphonmethane (sulphonal), diethylsulphone, diethylmethane (tetralon), bromdiethylacetylcarbamide (carbromal), chloral or chloralhydrate, chlorbutanol, phenylmethanonic acid (cinchofen), atophan, atquinol, dinitrophenol, dinitrophenol sodium and dinitrocresol sodium, except on the written prescription of a licensed physician, dentist or veterinarian.

Philadelphia

Dr. Frazier Honored—The *Annals of Surgery* devoted a recent issue to papers contributed by students and associates of Dr. Charles H. Frazier, John Rhea Barton professor of surgery at the University of Pennsylvania School of Medicine. An appreciation of Dr. Frazier was contributed by Dr. Alfred Stengel, vice president of the university in charge of medical affairs. Dr. Frazier, who is also professor of neurosurgery in the graduate school of medicine, has been a member of the faculty since 1895, having served as dean from 1901 to 1910.

Society News—The meeting of the Philadelphia County Medical Society, May 8, was devoted to addresses on anemia. Speakers were Walter J. Crocker, V.M.D., on "Architecture of the White Cells with Reference to the Schilling Count," Drs. Max M. Strumia, Bryn Mawr, "The Blood as a Tissue with Special Reference to the Red Cell," and William Egbert Robertson, "The Anemias from the Clinical Standpoint."—Drs. Richard P. Custer and Edward B. Krumbhaar, among others, addressed the Pathological Society of Philadelphia, May 9, on "The Histopathology of the Hemopoietic Tissues in Hemophilia."

Student Prizes Awarded—Three prizes in the annual student research competition at the University of Pennsylvania School of Medicine were awarded at a meeting of the Undergraduate Medical Association, April 25. Thomas E. Machella, Eckley, a senior, won the first prize, the Mary Ellis Bell award, for a technic for clocking the speed of blood flow in dogs. The John G. Clarke Prize went to Tzvee N. Harris, Philadelphia, a junior, for a study on immunizing factors in horse and human blood serum. The third prize, the Grayhe Simpson Priestley award, was given to Julian A. Sterling, Philadelphia, a junior, for a study on the presence and formation of antibodies in bile.

RHODE ISLAND

Dr. Kraus Awarded Gibbs Medal—The presentation of the Willard Gibbs Medal of the Chicago Section of the American Chemical Society to Charles August Kraus, Ph.D., Providence, R. I., took place, May 24, at the Stevens Hotel, Chicago, in recognition of his "outstanding work in the field of chemistry." Dr. Kraus, since 1924 professor of chemistry and director of research in chemistry, Brown University, has been field secretary of the Fellowship Board in Physics, Chemistry and Mathematics of the National Research Council since 1933 and from 1931 to 1932 was vice chairman of the division of chemistry and chemical technology of the National Research Council. He was awarded the Nichols medal in 1923.

TENNESSEE

University News—A collection of seventy-four books, fifty pamphlets and monographs and 159 magazines dealing with malaria has been given to the University of Tennessee College of Medicine, Memphis, by Dr. William H. Deaderick, Hot Springs National Park, Ark. The gift was made in recognition of work done on malaria by Dr. James B. McElroy, professor of medicine at the university, and chief of staff of Memphis General Hospital, according to newspaper reports.

Faculty Promotions at State University—The following physicians on the faculty of the University of Tennessee College of Medicine, Memphis, received promotions, March 28, among others:

Drs. William W. Riggs, Jerome P. Long, Jr. and James M. Brockman to be assistant professors of obstetrics
Dr. Matthew W. Seagrath, associate professor of gynecology
Dr. Isaac G. Duncan, assistant professor of urology
Dr. Joseph I. Mitchell, assistant professor in orthopedic surgery
Dr. Frank W. Smythe, assistant professor in surgery.

Birth and Death Rates Increased in 1934—Provisional figures issued by the state department of public health indicate that the number of recorded deaths in the state for 1934 was 29,771, with a rate of 10.9 per thousand of population, as compared with 27,599, with a rate of 10.2 in 1933. The birth rate increased from 17.8 in 1933 to 18.4 in 1934. The death rates in the principal causes of death were diseases of the heart, 146.8 per hundred thousand of population, an increase from 132.1 the previous year, pneumonia, 96.2, also an increase, tuberculosis, 88.4, a decrease from 93.8, cerebral hemorrhage, embolism and thrombosis, 78.3. Accidents and unspecified external causes increased from 66.6 to 74.3, largely because of 131 more deaths from automobile accidents. A measles epidemic resulted in a death rate of 16.3 for measles.

Health at Memphis—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended May 25, indicate that the highest mortality rate (18.3) appears for Memphis and the rate for the group of cities as a whole (18.3). For the corresponding period last year the mortality rate was 17.1 for Memphis and 11.5 for the group of cities. The annual rate for eighty-six cities for the twenty-one weeks of 1935 was 12.5 as against a rate of 12.4 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

WEST VIRGINIA

State Medical Election—Dr Charles G Morgan, Moundsville, was chosen president of the West Virginia State Medical Association at its annual meeting in Wheeling, May 7. The next annual session will be held at Fairmont.

Society News—Dr James Morrison Hutcheson, Richmond, addressed the Kanawha County Medical Society in a joint meeting with the Fayette County Society at Charleston, April 9, on "Atypical Features of Coronary Occlusion."—Dr Charles R. Austrian, Baltimore, was the speaker at a meeting of the Cabell County Medical Society, Huntington, April 11, on management of lobar pneumonia.—Drs Fred B. Quincy and George W. Easley, Williamson, addressed the Logan County Medical Society, Logan, April 10, on pyloric stenosis and infection of the hands, respectively.

WISCONSIN

Personal—Dr Robert G. Sayle, Milwaukee, recently observed the fiftieth anniversary of his medical practice.—Dr Bruno Schallern, Ripon, celebrated the fiftieth anniversary of his entrance into medical practice in March.

Radiology Meeting—The section of radiology of the State Medical Society of Wisconsin held its midyear meeting in Milwaukee, May 17-18. Guest speakers included Dr Leo G. Rigler, Minneapolis, who gave addresses on "Roentgen Observations on the Normal and Pathologic Interlobar Pleura" and "Roentgen Study of Leukemia of the Stomach and Its Relationship to Chronic Hypertrophic Gastritis." Dr Edward L. Jenkinson, Chicago, also spoke at the banquet on economics.

Society News—Drs Edwin J. Kepler and Howard K. Gray, Rochester, Minn., addressed the Brown-Kewaunee-Door Counties Medical Society at a meeting with the societies of Outagamie, Winnebago and Fond du Lac counties, April 25, on diabetes.—The annual meeting of the seventh district of the State Medical Society of Wisconsin was held in La Crosse, April 24, clinics were held at St. Francis, Lutheran, Grandview and La Crosse hospitals and addresses were made by Drs Frederic E. B. Foley, St. Paul, Minn., and Louis M. Warfield, Milwaukee, among others, on "Importance of Early Diagnosis in Management of Ureteral Stone" and "So-Called Heart Failure in Acute Infections," respectively.—Dr Alice Hamilton, Boston, and Carl R. Moore, Ph.D., Chicago, addressed the Medical Society of Milwaukee County, May 10, on "Industrial Medicine—A Stepchild" and "The Endocrines and Reproductive Function," respectively. The Milwaukee Professional Men's Orchestra presented a program.—Dr Bernard Fantus, Chicago, addressed the Milwaukee Academy of Medicine, May 21, on "Some Important New and Nonofficial Remedies."

HAWAII

Territorial Election—Dr Guy C. Milnor, Honolulu, was installed as president of the Hawaii Territorial Medical Association at its annual meeting, April 29, and Dr Lyle C. Phillips, Honolulu, was reelected secretary.

GENERAL

Changes in Status of Licensure—The Massachusetts Board of Registration in Medicine reported the following action:
Dr James P. A. Nolan, Brookline, reregistered as a physician, April 11. His registration had been revoked July 23, 1923.

The State Board of Medical Education and Licensure of Pennsylvania recently reported the following action:

Dr Edmund B. Ilyus, Lancaster, license suspended indefinitely, March 6, because of conviction on a narcotic charge. He was fined \$100 and placed on probation for five years.

Society News—Dr Walter C. Alvarez, Rochester, Minn., was chosen president-elect of the American Association of the History of Medicine at its annual meeting, May 6, and Dr William S. Middleton, Madison, Wis., was installed as president. The next annual session will be held in Atlantic City.—At a meeting of the American Association on Mental Deficiency, April 25, Edgar A. Doll, Ph.D., Vineland, N. J., was installed as president and Dr Benjamin O. Whitten, Clinton, S. C., was chosen president-elect.—The American Dermatological Association elected Dr Clarence Guy Lane, Boston, president at its meeting, May 3.—Dr Merrill C. Sesman, Boston, was elected president of the Harvey Cushing Society at its fourth annual meeting in New Haven, May 2-4. Dr Kenneth G. McKenzie, Toronto, Ont., was made vice president, and Dr Louise C. Eisenhardt, New Haven, secretary-treasurer. The next annual session will be held in Rochester, Minn.

Association of Medical Milk Commissions—The annual meeting of the American Association of Medical Milk Commissions at the Chalfonte Haddon Hall Hotel, Atlantic City, N. J., June 11, will open with a symposium on "the next step in the progress of certified milk." Included among the many speakers on the program will be Dr John L. Rice, commissioner of health of New York City, Dr Thomas Parran Jr., state health commissioner of New York, Dr William W. Bruer, director, Bureau of Health and Public Instruction, American Medical Association, Dr Samuel J. Crumbine of the American Child Health Association, New York, Dr Reginald M. Atwater, executive secretary, American Public Health Association, New York, Ira V. Hiscock, C.P.H., Yale University School of Medicine, New Haven, and James A. Tobey, Dr P.H. New York. On Monday, June 10, the Certified Milk Producers' Association of America will hold its annual meeting.

Salmon Memorial Medal—The Salmon Memorial Committee for Psychiatry and Mental Hygiene has donated to the American Psychiatric Association an award to be known as the "Salmon Memorial Medal." It will be presented from time to time by the association "to the person distinguishing himself in the field of psychiatry, by original contributions to that specialty or for outstanding accomplishment." The Salmon Committee on Psychiatry and Mental Hygiene was organized several years ago to perpetuate the memory of Dr Thomas W. Salmon, former president of the American Psychiatric Association. The council of the association voted to accept the medal during the annual meeting in Washington, D. C., May 13-17. During this session Dr C. Macfie Campbell, Boston, was named president-elect of the association and Dr Clarence O. Cheney, New York, was installed as president. Dr William C. Sandy, Harrisburg, was reelected secretary-treasurer. It was also voted to establish permanent headquarters at the New York Academy of Medicine, 2 East 103d Street, New York.

Report on Eye Defects in School Children—The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, with the cooperation of the National Society for the Prevention of Blindness, has published a revised edition of its bulletin "Conserving the Sight of School Children." Recent surveys indicate that about 12 per cent of all school children have defects in vision. Farsightedness is found to be first in frequency of the common defects, astigmatism second and nearsightedness third. The report recommends that schools take the responsibility for detecting eye defects and seeing that they are corrected. It is not necessary that the school furnish the services required; they may be obtained from family physicians, professional health organizations, community health centers or elsewhere, it points out. The technique of vision testing is described in some detail, and there is a chapter on lighting. Special provision for those seriously handicapped should be made, including arranging for such children to use the typewriter, teaching them to gather information through the sense of hearing, and providing books with large type for them and sight saving classes as part of regular school systems. At present about 6,000 children are enrolled in 458 sight saving classes maintained by 145 communities, but facilities are needed for about 44,000 other children, according to the National Society for the Prevention of Blindness.

Medical Bills in Congress—Changes in Status S. 5, after being amended in several respects, has passed the Senate, proposing to prevent the manufacture, shipment and sale of adulterated or misbranded food, drink, drugs and cosmetics and to prevent the false advertisement thereof. S. 2472 has passed the Senate proposing to pay an annuity to Frances Agramonte, the widow of Dr. Aristides Agramonte, a member of the yellow fever commission. S. 2584 has been favorably reported to the Senate, proposing to amend an act entitled "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever," by including therein the name of Gustaf E. Lambert (S. Rept. No. 733). S. 2625 has passed the Senate, extending the facilities of the United States Public Health Service to seamen on government vessels not in the military or naval status. H. R. 6995 has been reported to the Senate, proposing to reenact all laws in effect March 19, 1933, granting pensions to veterans of the Spanish-American War, including the Boxer Rebellion and the Philippine Insurrection, their widows and dependents (H. Rept. No. 974). The bill provides no pension for contract surgeons of the Spanish-American War. H. R. 7260, the Doughton social security bill, has been reported to the Senate, with amendments (S. Rept. No. 628). **Bills Introduced** S. 2793, introduced by Senator Wagner, New York, proposes to enact a workmen's compensation act for the benefit of employees.

engaged in interstate commerce. If an employer fails to provide the necessary medical, hospital and other services for an injured employee, after a request therefor, the employee may obtain them at the expense of the employer. H R 8109, introduced by Representative Chapman, Kentucky, proposes to authorize the erection of an addition to the existing Veterans' Administration facility at Lexington, Kentucky. H R 8169, introduced by Representative Monaghan, Montana, proposes to erect additional facilities to the existing veterans' facility at Fort Harrison, Montana. H R 8249, introduced (by request) by Representative Rankin, Mississippi, and H R 8294, introduced by Representative Robison, Kentucky, propose to reenact all public laws repealed March 20, 1933, granting medical or hospital treatment, domiciliary care, compensation and other allowances to veterans of the World War and their dependents for disabilities or deaths incurred or aggravated or presumed to have been incurred or aggravated in service.

CANADA

Hospital News—Dr Joseph S Stewart, superintendent of the Ontario Hospital, Toronto, has been appointed head of the Ontario Hospital at Hamilton, succeeding Dr Joseph J Williams, who has retired.—Sir Herbert Holt, president of the board of governors of the Royal Victoria Hospital, Montreal, has made a gift to the hospital of \$200,000, to be known as the "Herbert S Holt Foundation."

Society News—The annual meetings of the Canadian Public Health Association, the Ontario Health Officers' Association, the Canadian Tuberculosis Association and the Canadian Social Hygiene Council will be held in Toronto, June 3-5.—Dr Frederick T Campbell was elected president of the Calgary Medical Society at the annual meeting, April 2.—The College of Physicians and Surgeons of Alberta has recently begun publication of the *Alberta Medical Bulletin*.

FOREIGN

Bus Drivers and First Aid—The Danish ministry of public works recently decreed that buses not operated exclusively in towns carry a first aid kit containing standard equipment for first aid. Bus drivers are required to have taken courses in emergency aid from the Danish Red Cross or the Workers' First Aid Association.

Sixtieth Anniversary of Health Institute—The Institute of Public Health of the University of Budapest recently celebrated the sixtieth anniversary of its founding. The institute was established in 1874 under the direction of Prof Joseph Fodor, a student under Pettenkofer, according to an announcement. Prof Leon Liebermann succeeded Professor Fodor and the present director is Prof Julius Daranyi.

International Congress on Mental Hygiene—An announcement of plans for the second International Congress on Mental Hygiene to be held in Paris, July 27-31, 1936, states that typewritten texts of reports and communications must be sent to the chairman of the program committee before November 1. Applications to take part in the communications and discussions should be sent in advance to the chairman, Dr Rene Charpentier, 119, rue Perronet, Neuilly-sur-Seine, Seine, France. It is recommended that such application be made before Jan. 1, 1936.

Personal—Col. Alfred H Proctor of the Indian Medical Service has been appointed dean of the British Postgraduate Medical School to succeed Dr Malcolm H MacKeith who resigned for reasons of health.—Dr Howard W Florey, professor of pathology in the University of Sheffield, has been appointed professor of pathology at the University of Oxford.—Dr Victor G Heiser, who since 1915 has been connected with the Rockefeller Foundation, of which he was director for the Far East, was to retire January 1, according to the *International Journal of Leprosy*, and devote himself to furthering the work of the International Leprosy Association, of which he is president.

Society News—The International Organization of the Campaign Against Trachoma held its annual meeting in London, April 3 in conjunction with the meeting of the International Association for the Prevention of Blindness as guests of the Ophthalmological Society of the United Kingdom. Dr Emile de Grosz, Budapest, resigned as president of the organization against trachoma after serving since 1929. Dr Arthur F MacCallan, London was elected to succeed him.—The Tsunan Ophthalmological Society was recently organized and held its first meeting at Cheeloo University School of Medicine. Tsunan. Dr Eugene Chan head of the department of ophthalmology was chairman, Dr Chan was formerly a member of the staff of the Wilmer Ophthalmological Institute Baltimore.

Government Services

New Naval Hospital at Philadelphia

A new \$3,200,000 building for the U S Naval Hospital Philadelphia, with a capacity of 650 beds, was dedicated April 12. Speakers at ceremonies were Rear Admiral William C Watts, commandant of the Philadelphia Navy Yard, Congressman George P Darrow, Philadelphia, who was instrumental in procuring the federal appropriation for the hospital, Mayor Hampton L Moore, Brig Gen Frank T Hines, Washington, D C, veterans' administrator, Rear Admiral Perceval S Rossiter, surgeon general of the navy, Rear Admiral N M Smith of the navy civil engineers corps, Col Vincent A Carroll representing the American Legion, Harry J Crossen regional manager, Veterans' Administration, and Dr J Evans Scheehle, state secretary of welfare, representing the governor of Pennsylvania. The buildings comprise a fourteen story main hospital, nurses' quarters, hospital corps quarters, four sets of officers' quarters and a garage situated in a twenty-two acre plot in League Island Park near the Navy Yard. They replace an old building originally built in 1868, modernized from time to time and enlarged during the World War by the addition of temporary barracks. The old quarters will be razed immediately. Though not the largest, it is said to be the best

U S Naval Hospital Philadelphia

appointed of all naval hospitals. In addition to navy personnel it will care for the sick of the army, the Civil Conservation Corps, U S Employees Compensation Commission and the Veterans' Administration and will also provide an outpatient clinic for the Veterans' Administration for the entire Philadelphia area. Capt John D Manchester is the commanding officer, with a staff of thirty-two medical and dental officers and pharmacists, twenty-five nurses and 118 corpsmen, and seventy-five civilian employees.

Colonel Keller Honored

Colonel William L Keller, medical corps U S Army, was honored, May 16, when President Roosevelt signed an act of Congress to give him full active pay for the rest of his life regardless of retirement in appreciation of his valuable service, according to the *Washington Evening Star*. The bill also creates a new office to be known as consultant in surgery of the Army Medical Center, located at Walter Reed General Hospital. Dr Keller will be appointed to this position, but he may retire from active duty at his pleasure and continue to receive the full pay and allowances of a colonel, it was stated. Colonel Keller, who has been chief of the surgical service at Walter Reed for sixteen years and commanding officer of the hospital for the past five years, is director of surgery in the Army Medical School. He was graduated from the Medical College of Virginia in 1899 and served as active assistant surgeon of the U S Public Health Service for one year, when he entered the military service as a contract surgeon. He was commissioned a first lieutenant in the medical corps in 1902 and reached the rank of colonel in 1928.

Changes in the Public Health Service

Passed Asst. Surg. Austin V. Deibert, relieved at Atlanta and assigned at Quarantine Station, San Pedro, Calif.
Asst. Surg. Arthur B. Price, relieved at Marine Hospital, Seattle and assigned at Marine Hospital, San Francisco.
Passed Asst. Surg. Samuel J. Hall, relieved at San Francisco and assigned at Marine Hospital, Seattle.
Passed Asst. Surg. William W. Nesbit, relieved at Bryson City, N. C., and assigned at Marine Hospital, Detroit.

LONDON

(From Our Regular Correspondent)

May 11, 1935

The Selenide Treatment of Metastases in Cancer of the Breast

The medical treatment of cancer has proved uniformly disappointing but the recent work of Dr A T Todd with selenium compounds seems to be of some promise and at present holds the field in this country. In a paper on The Selenide Treatment of Mammary Metastases read at the Section of Radiology of the Royal Society of Medicine he argued that there was a defense mechanism in cancer resembling that in chronic infectious diseases. This mechanism was controlled by endothelial cells, which appeared to secrete substances that activated the rest of the tissue. These cells would take up any electro-negative colloid that came their way. If the colloid was of such a chemical nature that its breakdown simulated the metabolism of the cell, a greater defense would result. Some selenium colloids had this property in the correct dosage. His method of treating cancer is to impregnate the defense tissues with this colloid and activate it by repeated small doses of x-rays.

The treatment of mammary metastases by this method varies according to the condition present. In an inoperable case with neglected primary growth, removal of this especially if there is septic or hemorrhagic fungation, is desirable. The main mass and any enlarged gland easy of access are removed, but no attempt is made at radical removal. While healing of the incision is taking place, radium selenide is given weekly. Then 2 cc. of sulphur selenide is injected intravenously. If no reaction appears after four hours, the dose should be increased by 1 cc. the next week and so on until reaction occurs. The reactive dose is maintained until the reaction alters. A local reaction is shown by pain, stiffness or drawing sensations at the site of the growth and by increase of edema in connection with gland involvement, a general reaction is shown by malaise, nausea and occasionally a little pyrexia. The x-ray reaction usually comes on after four hours. It should be just perceptible and at most give the patient a poorish night. The average dose is 75 roentgens at 180, 30 cm distance, and screen 0.3 mm. of zinc.

Metastases after the usual incisional surgery should be treated by the routine method after a clinical and roentgen examination of the liver, lungs and skeleton. Any metastases found should be irradiated and any suspected site also treated. Hepatic metastases are very sensitive and the liver should not receive an x-ray dose exceeding 25 roentgens. Metastases after radium surgery (the radium dose calculated to cause necrosis) are usually nonreactive and the prognosis is not so good. Radium appears to break down all defenses, and metastases seem to appear more quickly and at unusual sites, the patients usually fail to react to selenide treatment.

Dr Todd thought that in the prophylactic treatment of supposed surgical cure the selenide treatment was likely to do most good. He recommends that every patient regarded as being surgically cured should have the full treatment for a year. Here reaction will be no guide. Colloid should be about 4 cc., x-rays about 75 roentgens. Dr Todd has not treated such patients, as his time is fully occupied in trying to improve the system and in working on cases otherwise untreatable. Although no special precautions are taken, recurrence is never seen in the incision notwithstanding that it is so frequent otherwise.

RESULTS

The results were given in twenty-seven cases of mammary metastases, quite inoperable and refused further treatment by

surgeon and radiologist, few were likely to have survived for more than a few months. Five patients are still under treatment. One of these has had continuous treatment for five years, another for four years, both are reasonably well. Two are doing well. One is doing badly. Two patients died from pneumonia, one year and eighteen months respectively after apparent cure. The necropsy in one failed to show any signs of carcinoma. Twelve patients are dead, most of them exceeded their expectation of life and about half had prolonged periods of relief from symptoms. Eight patients have been discharged as apparently cured. In four cases apparent cure has persisted for one year, in the other four for two years.

Drug Addiction Replaced by Tea Addiction in Egypt

Russell Pasha, chief of police in Cairo, in the report for 1934 of the Central Narcotics Intelligence Bureau, has given interesting details on drug addiction in Egypt. Statistics show how the work of the bureau has progressed in consequence of the growth of the international conscience as to the drug traffic. There is a steady decline in the number of addicts and the quantity of drugs seized at the frontiers. Unfortunately, drug addiction has taken another, though less injurious, form. A rapid growth of tea drinking has occurred among the Egyptian fellahen. Strong tea dust is boiled and reboiled and the beverage is taking the place of cannabis and diacetylmorphine, with disastrous results. Some of the fellahen spend almost all their daily wage on tea and now cannot work without it, with the result that their physique is deteriorating. A village headman has made the statement that where formerly four men hoed an acre daily now eight are needed. Russell Pasha says that it is a sociomedical problem of vital importance to Egypt to discover how to wean these people from the use of stimulants. Narcotics would have been a more accurate term.

Heavy Oxygen Water Isolated

After two years of research a young Manchester physicist, J B M Hervet, lecturer on physical chemistry at Manchester University, and Dr M Polyani, also of that university, have succeeded in isolating heavy oxygen water, i.e., water composed of hydrogen and the heavy isotope of oxygen. This is believed to be the first time heavy oxygen water has been obtained in this country, but two years ago it was obtained by Professor Hertz in Berlin. Heavy oxygen water must be distinguished from heavy hydrogen water (composed of heavy hydrogen and oxygen), which was discovered a few years ago in the United States. The chief advantage of heavy oxygen is that it will facilitate research in advanced organic chemical reactions. In ordinary water, heavy oxygen water is present to the extent of about one part in 500.

Deaths Due to House Fumigation

Two children have lost their lives from a cause unprecedented in this country—the fumigation of infested houses. Cyanide fumigation of a row of four houses was performed one evening and the occupants were allowed to return on the following day. They noticed the smell of the fumigating gas and an unpleasant taste in the mouth. They went to bed as usual. At 3 a.m. physicians were called. A girl, aged 5 years, was dead and another, aged 1 year, was found unconscious in another house. She was taken to a hospital and oxygen was administered but she also died. Three women, one man and a boy, aged 8 years, were also taken ill but recovered. At the inquest, evidence was given that the fumigation was done by a firm that specialized in the process and under the instructions of the health authorities. The man who performed it had six years' experience and had fumigated 1,000 houses without a mishap. He explained the process. The house was sealed up and then he put on a gas mask and conducted the fumigation.

At 9 30 p m, when he finished, he saw that every cupboard was open and also the doors and windows, so as to get full ventilation. He was satisfied that everything was all right and did not leave until 11 30 p m. He then placed a notice on the doors and delivered the keys to the health inspector. On being questioned he agreed that hydrogen cyanide was slower in getting away from padded furniture and bedding. He tested the atmosphere and bedding before leaving. When he left there might be some trace of gas in the house, as there would be for some days. The coroner did not think that there was anything in the evidence showing wilful negligence, which would justify a verdict of manslaughter. The jury returned a verdict of "death from misadventure" but added a rider that "in future, owing to the dangerous nature of the gas, more competent supervision should be given and two men should be employed, and the final certificate for reentry of the house should be given by the health officer."

Defects of the Social Insurance Law in France

Dr Pibrie, a practitioner in the southwestern portion of France, published an article in the March 9 issue of the *Journal des praticiens* on defects of the social insurance law in France. To facilitate the comprehension of certain portions of the article, explanatory notes will be added.

Dr Pibrie states that the law has now been in operation for more than four years and that he has come in contact with a sufficiently large number of the assured to be able to form a judgment as to its merits and defects. He takes up the latter first.

PREMIUMS

According to the social insurance law, any employee who earns less than 15,000 francs (about \$1,000) is obliged to be insured. The premium varies according to the wages, calculated on an annual basis. The employer is obliged to pay one half of the monthly premium and the employee the other half.

Pibrie states that at the period (1930) when the law went into effect the employer did not object to paying his portion of the premium. It was considered as an extra tax but was not felt to be a burden until the economic crisis struck France, a little later than in other countries. The employer now feels that these premiums are a source of expenditures without any corresponding financial return, and recourse has been taken in one of two ways by some at least of the employers. They have either raised the price of their products, which of course has been passed on to the consumer with resultant augmentation of the cost of living, or they have adopted a simpler plan, consisting in discharging employees, thus adding to the government's burden of aiding the unemployed, with the result that increased taxes make living more costly for those who are employed.

On the side of the employee, many have found that the obligatory monthly premium is a burden. Workers in non-agricultural pursuits feel that the amount they are obliged to contribute is out of proportion to that paid by those engaged in agriculture, which is only one fifth of that paid by those not working on farms.

UNNECESSARY FORMALITIES IN PAPER WORK

According to Pibrie, the formalities in paper work are excessive. Perhaps, as he jokingly asserts they are made so to discourage the sick worker from asking recompense for a single medical consultation and prescription. The assured, after having been examined and prescribed for by the physician, must go to the nearest city hall to ask for a blank to be filled out by the employer. The latter must then be requested to

state that the employee has paid his share of the premiums regularly. (The employer is obliged to send in a monthly statement with his half of the premium, giving the names and amounts paid by each employee according to the wages earned in the corresponding month.) Then the sick assured must return to the city hall to be given the blanks to be filled out by the physician and the pharmacist. The latter two must next be visited to have the sickness blanks filled out, which are to be sent to the local combined examining and disbursing governmental office, termed the Caisse. Altogether, for a single illness, there are about seven calls to be made to comply with the regulations regarding reimbursements.

REIMBURSEMENTS

According to the social insurance law, no indemnity can be claimed for the first four days of any illness. In France, the assured worker has the privilege of choosing his own physician, whom he pays directly without waiting for the Caisse to reimburse him. There are two methods, one according to which payment for each medical visit is made immediately by the Caisse and a second, at the termination of a long illness. In the former case the fee schedule established by the joint action of the Caisse and the representatives of the medical profession vary according to different "departments" (counties) of France. Pibrie states that in his locality a physician charges 18 francs (\$1.25) for a house and 15 francs (\$1) for an office visit. The Caisse reimburses the assured to the extent of 9.5 francs for either without discrimination. According to the law, the assured should receive from 80 to 85 per cent of his medical expenses, but the figures quoted show that only 50 per cent is paid for house calls and 64 per cent for office consultations.

In the case of "lump sum" reimbursement, a curious situation has arisen, which has been the subject of legal procedures against the Caisse. The assured cannot claim indemnity for any single illness for a period longer than six months. He can then claim a "lump sum" for any medical outlays made during such period. After the lapse of the six months, two months must elapse without reimbursement before another six months period can begin. In such illnesses as syphilis, tuberculosis, malaria or diabetes, which are of longer duration than six months, the position of the assured, who must pay his own medical expenses during the two months interval, is not an enviable one, especially when he has paid his premiums regularly for years. This six months limit of indemnity was inserted in the original law to avoid fraud, but it has led to much misery hence a modification is now being discussed to suppress the two months interval.

Pibrie states that the amount allowed by the Caisse for illness, operations and confinements is far below the actual expenses incurred by the assured.

SUPERVISION OF THE SICK ASSURED

The supervision of the sick assured is twofold, viz., by the Caisse and by the medical man who represents it. Unless the latter is broadminded and keeps abreast of the progress constantly being made by his nongovernmental paid colleagues, there is constant friction as to the amounts to be allowed the assured for medical outlays. Pibrie also maintains that some of the nonmedical officials of the Caisse conduct themselves toward the assured in an unnecessarily arbitrary manner. To avoid unnecessary medical visits, the medical supervisor possesses the power of appealing to the departmental (county) medical association, who can expel a member convicted of collusion with a sick insured worker. The law still allows too many opportunities for friction between the nonmedical officials of the Caisse or local collecting and disbursing agencies and their own medical control representative, not only as to the diagnosis and treatment of ailments but also as to the reimbursements to be given for certain maladies.

HOW TO CORRECT THE DEFECTS

As to premiums, Pibrie believes that the employer should not be called on to pay more than half the amount paid by the employee, since the former derives absolutely no benefit from the law. As to the paper work, a simple medical certificate, without diagnosis, stating that X is suffering from an illness of slight, moderate or severe degree, given to the employer should suffice. This certificate can be sent to the city hall, as in the case of industrial accidents, by the employer, who also sends his own certificate at the same time. As to reimbursing the assured, they ought to receive nearly as much as they are obliged to pay out for house and office visits of their medical attendants. The fees allowed for operations are also inadequate, so that the assured must make up the difference. A limit of six months for chronic ailments is also a hardship on such patients and overlooks the fact that the law was made to aid the sick worker and not to exhaust his savings. If control is needed in a given case, it should be the task of the medical supervisor of the Caisse, and this visit should take place in the presence of the attending physician, so that the latter can justify the number of visits made and help to verify the diagnosis. Control by civilian officials of the Caisse should be made, say, within one month after the filing of the sickness blank. Altogether the law in France at least is far from ideal. It has been modified a number of times and still needs to have important changes made.

April 1, 1935

New Decisions on Sterilization and Castration

The Berlin Medical Society took recently as the theme of its session the subject "A Year of the Sterilization Law." A jurist emphasized that, as far as possible, a petition requesting sterilization should be filed by the patient with the hereditary defect. The decision of the eugenics court may often be rendered without the person affected appearing, which saves the patient the pain of an unpleasant hearing. In many cases (for example, in cases of epilepsy) an examination of members of a family is necessary.

According to Professor Gohrbandt, sterilization of the man should be confined to a so-called blocking operation, in which one may choose between vasoligation, vasofissure, vasoresection and destruction of the epithelium. The intervention may be carried out without pain. Gohrbandt himself prefers resection, he resects a portion 6 cm long, in order that no patient, after the operation has been performed, may conceive the notion of having the severed portions of the spermatic cord reunited. Whether the seminal vesicles contain spermatozoa is not definitely known, but, according to experiments on animals and cadavers that he has carried out, they frequently do contain spermatozoa. Hence Gohrbandt takes the precaution, following resection, to destroy any spermatozoa that may be present.

The clinical aspects of the legal sterilization of the woman were treated by Professor Ottow, at whose school of midwifery 311 women have been sterilized. It is necessary that, before the intervention, a woman be carefully examined to determine whether an operation is indicated and, if so, how the operation should be performed. The examination should be made on admission to the hospital and should be repeated under anesthesia. Finally, a third examination must be made on opening the abdominal cavity, which is to be regarded as an exploratory laparotomy. In two of his cases, following the opening of the abdominal cavity, it was decided to desist from the operation for sterilization. In another case, a woman who had been ordered by the eugenics court to be sterilized was already sterile owing to the absence of uterus and vagina. In further cases sterilization was not resorted to, because of

the discovery of cancer, aplasia of the uterus, and the like. The sterilizing operation may be performed by means of laparotomy or by the vaginal route. The abdominal operation is contraindicated in severe cases of idiocy and psychosis. The cosmetic aspects especially point to the vaginal operation, but this method should not be used if there are changes in the adnexa. The chief principle involved is, of course, to utilize a reliable blocking method to keep the sperm away from the ovum. This is best accomplished by removal of the tube, since no other method offers 100 per cent of security. In adnexa complications the sterilizing operation should not be carried out. In schizophrenic subjects there is an increased danger of infection. In his series of cases, Ottow found fifty-one instances of organic complications, in thirteen of which the adnexa were involved, in thirteen cases myomas and in thirteen cases ovarian cysts were discovered. The sterilization law does not provide for secondary operations that are justified by secondary observations, thus the operator finds himself in a difficult position, since at times an urgently indicated intervention must be carried out at his own risk, without the legally necessary permission of the patient. In 258 cases Ottow applied sterilization to women by the abdominal incision and in forty-two cases by the vaginal route. No grave complications as the result of the operations were observed, in five cases, severe hematomas developed, caused by the restlessness of the patients. No marked psychic effects of the intervention on the patients could be observed.

Professor Stoeckel, director of the Frauenklinik of the University of Berlin, stated that 100 per cent of efficiency in the sterilization of women can be demanded of no method. A few cases are bound to result fatally, since emboli occur following much less grave interventions. He regards the Madlener method as the best operation for sterilization. Of 4,000 operations in which this method was followed, only four were failures, which may be considered an optimal result. The alleged failure of this method in roentgenologic postoperative examinations is due to the fact that the roentgen contrast agent was injected under much higher pressure than was contemplated. The sterilization law provides that the tubes must be operated on and thus prescribes, in some cases, wrong operative interventions, for instance, if one must detach the tubes from a myomatous uterus and must leave the diseased uterus in the organism.

The director of the second Frauenklinik of the University of Berlin, Prof. G. A. Wagner, holds that failures after the Madlener operation are not so rare, particularly tubal pregnancies are apt to occur, in fact, they are facilitated by the intervention. Wagner does not share Ottow's hesitation about removing the tubal corners. He considers it a serious defect in the sterilization law that it insists on ligation of the tubes. In weak-minded women Wagner recommends extirpation of the uterus, because such persons, after their dismissal, frequently attract undue attention from the opposite sex and may easily become victims of gonorrheal infection. Gonorrhea of the cervix is most resistant to treatment, and, in a roundabout way, the sterilization of a woman with healthy hereditary qualities might result if her husband transmitted to her gonorrhea acquired in this manner. It is evident that some valuable observations have been collected. This is apparent also from the previously published figures on the activities of various eugenics courts. In the eugenics court of Wuppertal (Rhine-land), during the first year of its existence, approximately 1,000 petitions for sterilization were filed. In about 800 cases the petitions were granted, and about 600 interventions have been carried out. In the eighteen eugenics courts in Thuringia (central Germany) 3,178 petitions for sterilization have been filed, 2,472 of which have been heard before these courts. In 2,303 cases the petition was granted, and in 1,395 cases sterilization has been carried out.

The following decision tends to establish a precedent. The body having jurisdiction opposed in one instance the enrolling of a peasant family in the so-called *Erbhofrolle* (whereby a farm becomes indivisible and is always handed down to the oldest child), because for generations tuberculosis had been widely prevalent in this family, and advised that the farm be divided. The eugenics court, however, refused to render such a decision because of tuberculosis, for, according to present-day medical knowledge, tuberculosis is not a disease that is always transmitted to offspring. In another instance the eugenics court refused a petition for the sterilization of a student of music, the reason assigned being that in this case (by exception) sterilization should not be performed, because of the exceptional mental qualities of the patient, although indeed, he presented a type of melancholy, or of manic-depressive insanity, which falls within the scope of the sterilization law. In all three instances of such a disorder in the student's family the precipitating cause took effect only on the appearance of external, nonhereditary factors. This was therefore a pathologic hereditary tendency of much less potency than the essential group of hereditary mental diseases which develop of themselves without any external precipitating cause. Hence the court assumed that the offspring of this student, under normal living conditions, would probably escape an attack of the disorder. The court's second reason for its decision also establishes an important precedent. The petition involves an artist possessing unusual gifts, who is likely to transmit his gifts to his offspring. Likewise Professor Bonhoeffer, psychiatrist of Berlin takes the attitude that the sterilization law should not be applied to persons of the type mentioned. In a family many members of which possess unusual qualities the chances of a descendant having serious hereditary defects may reasonably be risked by society if, on the other hand, valuable hereditary qualities are likely to be inherited. There are, to be sure, some jurists who object to this "exceptional treatment of persons with talents."

With reference to the expense arising from the application of the sterilization law, ministerial decisions have become necessary. If neither a *Krankenkasse* nor a welfare organization can be expected to assume the costs, and the patient is unable to pay them, the central government must assume them.

Prof Fritz Lenz, of the University of Berlin called attention, in an address before the Emperor William Society for the Advancement of Science, to the danger arising out of the fact that hereditary defects are transmitted to offspring not only by persons with evident hereditary defects but also by persons who are apparently healthy. Hence it appears to him advisable to sterilize also healthy persons who might produce offspring with hereditary defects. This would apply, for example, to persons who present only slight signs of mental disease. On the other hand, from a practical point of view, a radical application of this principle is not advisable, for, according to his computation, it would affect 20 per cent of the population. Hence it is not likely that these far-reaching demands will be taken seriously by the centers having jurisdiction in the matter.

Lenz called attention to the need of combating the tendency, manifest in recent years, for the proletariat to gain possession of the intellectual professions. The danger of an increasing lowering of racial qualities—of the average intellectual level—is greater than is generally realized.

In Saarbrücken Lenz instituted a research on children that had attended school four years with a view to ascertaining what connection there might be between the scholarship of the pupils and the number of children in their respective families. According to this research the average scholarship of the pupils grows less as the number of children in their respective families increases. It is evident therefore, that the promotion of the population alone is not all that is needed. There must

be also a selection of the competent pupils, or those with more than average endowments.

While such questions as this are receiving considerable attention in Germany, no special eugenics bureaus are to be created in the larger cities and districts for the solution of these problems, which, in point of fact, belong to the field of the public health services. On the other hand, an endeavor is being made to give the teachings of racial hygiene the widest publicity for example, in the *Staatsmedizinische Akademie* in Berlin, a special three-day course of instruction in racial hygiene and the theories of heredity was recently organized for the benefit of the pastors.

For all the questions that have to do with racial hygiene the authorities are seeking to extend the basic knowledge. In Bavaria a card index of injuries of a hereditary and an environmental origin, as observed in clients of welfare departments has been created in order to determine what are hereditary and what are environmental injuries. On the basis of this material, one will seek to discover what kind of treatment and care are the best for the various types.

The same purpose is served by the published observations of the *Erbbiologische Bestandsaufnahme* of the hereditobiologic central of the League of the *Krankenkassen* in Berlin, concerning which the director Dr W. Tourné, has issued a report. About 2,000,000 "sickness cards" of the insured are being scrutinized. Approximately 400 cases are studied each month and 2,200 cases have been studied thus far, 1,311 of which have been completed. Thus far, 606 patients have been reported to the health officer of the district as subject to the application of the sterilization law—which amounts to 46.9 per cent of the completed cases.

Of the 2,200 cases scrutinized thus far, it was found that 456 showed no evidence of serious hereditary defects; forty-one patients were too old for sterilization to be of value, and thirty-three had already been sterilized.

VIENNA

May 2, 1935

The New Social Insurance Law

A new law pertaining to industrial social insurance was promulgated April 1. In keeping with the reorganization of the Austrian federal state, such a law had long been promised. The details of the drafting of the law were kept secret until the revision had been completed. By reason of the authoritarian form of government in force in Austria, no further changes in the law may now be made. It is probable that the selected representatives of the medical profession were not asked to sit in at the deliberations or, if so, were not called on to express their views. The results for the physicians have been calamitous as has been emphasized in several medical journals. The law consists of seven principal sections, only two of which concern the medical profession directly, namely (1) the administration of the *Krankenkassen* for workmen and for employees and (2) the provisions for the transition period. With regard to the latter it is important to note that during a transition period of three months dating from the promulgation of the law the previous arrangements will remain in force, until the public and the authorities have become familiar with the new provisions. The new law is to be effective for a period of five years. At the end of this period it will be seen what changes in the law are needed. As the law is designed to effect economies in social welfare the previous performances for the benefit of insured members must be materially reduced. Allowances for medical aid, hospital aid, convalescence aid and vacations, cash benefits and pensions will be diminished, so that the effects on the public health will certainly not be especially favorable. Here only the provisions affecting the medical profession can

be mentioned. For the performance of common tasks, in the field of health insurance, all the *Krankenkassen* of the workmen and all the *Krankenkassen* of the employees will be combined to form a main league. These two groups together, along with the still existing pension-insurance organizations, will form a federal league of social insurance institutes. In every district working mergers of the *Krankenkassen* will be formed, on these will rest the obligation of supplying medical aid (including obstetric aid, dental aid and sick benefits). They will also have charge of financial arrangements with the physicians, and the creation and management of pharmacies and therapeutic institutions to be used in common. For the assurance of medical aid for the members and for the amicable solution of all questions that arise in that connection, every working merger will appoint a physicians' committee, to be composed equally of representatives of the working merger and the corresponding professional organization of physicians. The chairman will not be a member of the medical profession. The treatment of the members of the *Krankenkassen* will be solely in charge of approved physicians, dentists and dental mechanics, who will be recompensed on the basis of the work performed and will no longer receive a fixed monthly compensation, as has been the rule of late in the *Krankenkassen*. In accordance with the rules of panel practice, the physicians who apply are engaged to furnish medical aid to the insured members of the social insurance system (that is, members of the various main leagues or of the federal league), if they can fulfil the following conditions: 1. Candidates must be citizens of Austria and must have a doctor's degree from the medical department of an Austrian university. 2. Practising physicians must have had at least four years of medical activity, with a minimum of three years' experience in a public sanatorium or hospital, and training in surgery, internal medicine and obstetrics, furthermore at least three months service as locum tenens of a practitioner. 3. Specialists must have had such training as entitles them to assume the title of specialist. The same rule applies to dentists, and, in addition dentists must have had two years experience in dental practice. 4. Every physician seeking admission to panel practice must furnish evidence of exemplary citizenship and of good professional behavior. 5. A candidate may have no further fixed income from other permanent medical employment amounting to 12,000 shillings (\$2,280) a year. (This provision is designed to prevent any person from deriving a double income from public funds—a provision of questionable value.) The last mentioned provision does not apply, however, to specialists. The admission of a candidate to panel service under the social insurance act, even though he has fulfilled all these conditions, is left to the discretion of the physicians' committee, a fact that will constitute an exceedingly severe test of the uprightness of character of the persons serving on this committee. With regard to the compensation of physicians who are engaged in the social insurance service, the following principles obtain. As a rule, no fixed salaries are paid but the services of physicians are compensated according to a point system which is supposed to have been worked out accurately. Every physician will be compensated according to his individual performances. Every prescription or visit or other performance (operations, examinations, application of bandages, consultations, and the like) entitles him to a certain number of points. The value of the point will fluctuate, but always with the condition that the amount of money or the percentage allowed for medical aid must always be made to suffice. The compensation allowed for medical aid will thus vary from year to year. But the complications extend further. The point value for the workmen's *Krankenkassen* may be different from the point value for the employees' *Krankenkassen*, being dependent on the funds available in the respective treasuries. Moreover, the physicians' committee may for special reasons depart from the

principle of compensation according to individual performances—not only in a given district or in parts of a district but also with respect to individual physicians, and instead may establish a fixed salary. Thus, the way lies open not only for arbitrary decisions but also for differentiation and discrimination among the panel physicians, which would be directly opposed to the previous regulations and which will likely furnish occasion for complaints. The regulation of the provisions applicable to the transition period is likewise important. When *Krankenkassen* are dissolved or when their physicians are no longer permitted to serve on the social insurance panel, the following provisions come into effect. A physician who has not yet served ten years may be notified and dismissed within a year after the beginning of the operation of the new law. In that event he will be entitled to an indemnifying sum, or dismissal wage the amount of which will depend on his length of service. If he is nevertheless admitted later to the panel he must return such sum—in monthly payments if desired. If however, a dismissed panel physician has served more than ten years he may be given a pension. Any agreements previously entered into by and between the panel physicians and the *Krankenkassen* to the effect that such panel physicians may not be dismissed from service without cause have been declared invalid. If a pensioned physician is again admitted to the panel he will receive no pension during the time of such activity. In all these matters the physicians' committee renders a decision as it sees fit. It will be seen, therefore, what great power the committee exercises and how wretched the lot of the medical profession has become, now that private practice has almost entirely disappeared. In line with other economic measures, a regulation has been adopted that only certain medicines may be prescribed. Such restrictions in the past have often given rise to complaints on the part of patients because the panel physicians objected to prescribing certain specialties. Now such complaints will doubtless become even more frequent.

In the whole law there is at least one feature that meets the desires of a large number of physicians, namely, the provision that the patient shall not be bound to accept a certain physician but may select in his home town any physician on the panel in whom he has confidence. But there is a certain danger associated with the free choice of physician, for not all physicians are admitted to the panel. It is feared that too strong an influence will be exerted by political, religious, national and economic factors. The impression that the whole law makes on the medical profession is unfavorable, and its revision will be made an urgent demand of all competent representative physicians.

In the foregoing the impairment of the previously recognized rights of the members of the *Krankenkassen* has not been discussed. Of course, the members are not satisfied with the law, medical considerations are not the chief reason, although the reductions in the performances will doubtless exert considerable influence on the general public health. There will be fewer opportunities for recovery of health, fewer therapeutic aids, less support in case of illness, and fewer persons adequately insured against disease—that is, fewer persons well cared for.

Decrease in the Number of Medical Graduates

For the first time since the close of the war, the number of students in Vienna securing the degree of doctor of medicine shows a decrease. During the school year immediately preceding the outbreak of the war (1913-1914), 385 men and women obtained their doctor's degree in medicine. In 1924-1925 the number had risen to 743 and for a number of years then it did not vary greatly from this figure. In 1932-1933 the number dropped to 521, and in 1933-1934 to 442. The decrease is an evident expression of the poor economic situation of the medical profession.

Marriages

GEORGE WILLIAM CROFT, Jacksonville, Fla., to Miss Anne Capers Haselden of Charleston, S C, May 16

DONION RANDOLPH MARTIN, Raleigh, N C, to Miss Mary Elizabeth Roof of Paducah, Ky, May 16

MAURICE BAINTON THOMPSON, Bloomfield, Conn, to Mrs Mary Waite Thomas of Hartford May 9

EDWARD M HOLMES JR, Richmond, Va, to Miss Sarah Daily Walsh of Norfolk, April 27

CLARENCE E. QUAIFF, Galesburg, Ill, to Miss Florence Hefte of Spokane, Wash, May 3

CHARLES SUMMEY BRITT to Miss Margaret Todd, both of Charlotte, N C, May 15

JOHN M KARCH, Cincinnati, to Miss Rosemarie Brinck of Dayton Ohio, recently

ULFERT R ULFERTS to Miss Mary Edwina Smith, both of Mena, Ark, May 3

CHARLES HOLMES BOYD to Miss Emily Gould West, both of Baltimore, May 24

HENRY R MCCARROLL, St Louis, to Miss Nina Snyder, recently

Deaths

Junius Claiborne Gregory ♂ Colonel, U S Army, retired Evanston Ill, Medical College of Virginia, Richmond, 1900, fellow of the American College of Surgeons, in 1907 entered the medical corps of the army as a captain and rose through the various grades to that of lieutenant colonel in 1917, served during the World War, retired in 1922, returned to active duty in 1922 and in 1930 retired for disability in line of duty, with rank of colonel, at one time assistant clinical professor of military medicine, Rush Medical College, Chicago, aged 59 died, April 26 of thrombophlebitis with right pulmonary and coronary embolism

Georgia Adell Filley ♂ Battle Creek, Mich, University of Illinois College of Medicine, Chicago, 1913, member of the Medical Society of the State of New York and the American Psychiatric Association, formerly a medical missionary in China, aged 64, at one time on the staffs of the Toledo (Ohio) State Hospital and the Battle Creek Sanitarium, where he died, April 16, of atrophic cirrhosis of the liver

Kenneth Millan, Brooklyn, Queen's University of Medicine, Kingston, Ont, Canada, 1920, member of the Medical Society of the State of New York, served with the British Army during the World War, on the staffs of the Caledonian Hospital and Brooklyn Hospital, Brooklyn, and the South Nassau Communities Hospital, Rockwell Center, aged 43, died, April 21, of meningitis

William Ropes May ♂ New York, Harvard University Medical School, Boston, 1898, associate in diseases of children, Columbia University College of Physicians and Surgeons, served during the World War, on the staffs of the Willard Parker Hospital, Hospital for Ruptured and Crippled and the City Hospital, aged 61, was found dead in bed, May 3

Edward Lambert Twombly, Boston, Harvard University Medical School, Boston, 1886 an Affiliate Fellow of the American Medical Association formerly instructor in gynecology at the Tufts College Medical School, for many years on the staff of St Elizabeth's Hospital, aged 75, died, May 10, of coronary thrombosis and carcinoma of the nose

Harry B Walter, Harrisburg, Pa, Jefferson Medical College of Philadelphia 1881, member of the Medical Society of the State of Pennsylvania, past president of the Dauphin County Medical Society at one time member of the board of education, for many years on the staff of the Harrisburg Hospital, aged 80, died April 25, of intestinal obstruction

Adelard Eugene Gendron ♂ River Falls Wis, School of Medicine and Surgery of Montreal, Que., Canada, 1893 past president of the Pierce-St Croix County Medical Society, city health officer, served during the World War, on the staff of the River Falls City Hospital aged 64, died, April 20, of carcinoma of the intestine

Neil Sutherland MacDonald Fort Snelling Minn, University of Michigan Department of Medicine and Surgery, Ann Arbor 1895 fellow of the American College of Surgeons, served during the World War connected with the Veterans Administration Facility aged 63 died May 3, of angina pectoris

James Lyman Whitney ♂ San Francisco, Harvard University Medical School, Boston, 1905, at one time instructor, assistant clinical professor and assistant professor of medicine, University of California Medical School, served during the World War, aged 53, died, March 12, of coronary thrombosis

Clarence Kelley Gilder, Carbon Hill, Ala, University of Alabama School of Medicine, Mobile, 1918, member of the Medical Association of the State of Alabama, past president of the Walker County Medical Society, member of the state board of health, aged 42, died, April 26, of streptococcal pneumonia

William Edward Miller, Colwyn, Pa, Medico-Chirurgical College of Philadelphia, 1899, member of the Medical Society of the State of Pennsylvania, member of the local board of health aged 64, died, April 12, in the Lankenau Hospital, Philadelphia, of pneumonia and acute nephritis

Benjamin Carey Geeslin, Arkansas City, Kan, Chicago Physio-Medical Institute, 1890, member of the Kansas Medical Society, for sixteen years a member of the board of education, aged 72, died, March 22, of coronary thrombosis, while attending a basketball game in Topeka

John William Lee, Waterloo, Ala., Kentucky School of Medicine, Louisville, 1890, member of the Medical Association of the State of Alabama, also a minister, aged 83, died, April 23, in the Eliza Coffee Memorial Hospital, Florence, of bronchopneumonia, following influenza

Leslie Ambrose Kuhn, Wyatt, Ind, Jenner Medical College Chicago, 1906, member of the Indiana State Medical Association veteran of the Spanish-American and World wars, aged 56, died, March 13, in St. Joseph Hospital, Mishawaka, of cerebral hemorrhage

Peter William Fox ♂ New Britain, Conn, University of Vermont College of Medicine Burlington, 1911, on the courtesy staff of the New Britain General Hospital, aged 49, died, April 15, of brain tumor, chronic myocarditis and hypostatic pneumonia

Charles Gresham McEachern, Biloxi, Miss, University of Nashville (Tenn.) Medical Department, 1900, member of the Mississippi State Medical Association, aged 60 was killed, April 25, when the automobile in which he was driving overturned

John Joseph Mangan, Lynn, Mass, College of Physicians and Surgeons, Boston 1891, Harvard University Medical School, Boston, 1904, member of the Massachusetts Medical Society, aged 77, died, March 29, of cerebral hemorrhage

Jerry Walter Gwin, Bessemer, Ala, University of Alabama Medical Department, Mobile 1917, member of the Medical Association of the State of Alabama, aged 44, died, March 28, in a hospital at Birmingham, of gastric ulcer and uremia

Clarence Edward Kylander, Pittsburgh, University of Pittsburgh School of Medicine, 1931, member of the Medical Society of the State of Pennsylvania on the staff of the South side Hospital, aged 34, died, April 24, of pneumonia

Osman Franklin Kinloch, Troy N Y, Albany (N Y) Medical College 1879, member of the Medical Society of the State of New York served during the World War, aged 82, died, March 31, of myocarditis and arteriosclerosis

James Wilson Miller ♂ Cincinnati, Medical College of Ohio Cincinnati, 1899, at various times on the staffs of the Cincinnati General, Good Samaritan and Children's hospitals, aged 64 died, April 28 of cerebral hemorrhage

Rushmore Lape, Fair Haven, Vt., Albany (N Y) Medical College 1877, an Affiliate Fellow of the American Medical Association, town health officer member of the school board aged 80, died, May 3, of coronary thrombosis

Ernest Lowrey, Excelsior Springs, Mo Marion Sims College of Medicine, St Louis, 1892 member of the Missouri State Medical Association, aged 64, died, April 1, in St Joseph Hospital Kansas City, of cerebral hemorrhage

William Nelson Giles Wataga, Ill Keokuk (Ia) Medical College, 1898, member of the Illinois State Medical Society, at one time mayor of Wataga, aged 77, died April 25, of diabetes mellitus and coronary thrombosis

Frank Rudisill Bealer, New York, Emory University School of Medicine, Atlanta, Ga, 1917 member of the Medical Association of Georgia, fellow of the American College of Physicians, aged 42, died, April 19

Elsy Nichols Morgan, South New Berlin N Y Baltimore Medical College, 1897, member of the Medical Society of the State of New York, aged 65 died March 11 of chronic myocarditis and coronary embolism

Dwight Shumway Moore, South Pasadena, Calif University of Nebraska College of Medicine Lincoln, 1887, member of the California Medical Association, aged 68, died, March 16 of myocarditis

Henry Dewey Ribble, Blacksburg, Va (licensed in Virginia under the exemption law of 1885), member of the Medical Society of Virginia, aged 82, died suddenly, March 1, of cerebral hemorrhage

Thomas Walker, Wynne Wood, Okla, Vanderbilt University School of Medicine, Nashville Tenn 1891 member of the Oklahoma State Medical Association, aged 68 died April 27, of endocarditis

Abraham Groves, Fergus, Ont Canada University of Toronto Faculty of Medicine 1871, medical superintendent and owner of the Royal Alexandra Hospital, aged 87 died May 12, of pneumonia

George Kasper Baier @ Washington, D C, Columbian University Medical Department, Washington, 1898 served during the World War, aged 59, died, April 22, of pulmonary tuberculosis

John Mauls Ferrell, El Dorado, Ark Bennett College of Eclectic Medicine and Surgery, Chicago, 1906, aged 52, died, recently, in the Henry C Rosamond Memorial Hospital of pneumonia.

Herbert Walter Longworth, Kingsport, Tenn, University of Tennessee College of Medicine, Memphis, 1930 city health officer aged 27, died, May 1, in a local hospital of spinal meningitis

Isaac Marion Gravlee @ Mobile, Ala, Tulane University of Louisiana School of Medicine, New Orleans, 1920, member of the Radiological Society of North America, aged 38, died March 27

Edward William Gahan, San Diego, Calif Indiana College of Medicine and Midwifery, Indianapolis 1885 aged 72 died March 28, of coronary thrombosis, arteriosclerosis and diabetes mellitus

William H Popplewell @ Lamar, Mo, Barnes Medical College, St Louis, 1898 secretary of the Barton County Medical Society, aged 60, died, April 21, of cardiovascular renal disease.

William A. Campbell, Pyriton, Ala (licensed in Alabama in 1903), member of the Medical Association of the State of Alabama, aged 81, died, April 9, of influenza and pneumonia

Albert Jabesh Harris @ Buffalo, University of Buffalo School of Medicine, 1903 aged 63, died, May 10 in the Deaconess Hospital, of cerebral hemorrhage and myocarditis

Charles W Austin, Mangum, Okla, Memphis (Tenn.) Hospital Medical College, 1895, member of the Oklahoma State Medical Association, aged 74, died, April 3, of uremia

Philip C Marquart, Springfield, Ohio, University of Louisville (Ky) Medical Department, 1894, member of the Ohio State Medical Association, aged 63, died, April 9

John Ray M Frawley @ Wausau, Wis, Milwaukee Medical College, 1910 county coroner, on the staff of St Mary's Hospital, aged 52 died May 6, of pulmonary fibrosis

Henry S Morris, Mammoth Spring, Ark (licensed in Arkansas in 1903), bank president, aged 61, died, April 17, in the Baptist Hospital, Springfield, Mo, of cholecystitis

Joseph Graham, Washington, D C, University of Pennsylvania Department of Medicine, Philadelphia, 1901, aged 56, died, April 29, of arteriosclerotic heart disease.

Albert Washington Lane, Gadsden, Ala, Atlanta (Ga) School of Medicine, 1906, member of the Medical Association of the State of Alabama, aged 52, died, April 5

Ernest Christian Fisher, Richmond, Va., University College of Medicine, Richmond, 1900, member of the Medical Society of Virginia, aged 59, died, April 15

Thomas Arthur Lynch, Omaha Creighton University School of Medicine, Omaha, 1931, aged 29, died, April 30, in St Catherine's Hospital, of septicemia

Alfred Earle Kinney, St Albans, N Y, University of Oregon Medical School, Portland, 1914, served during the World War, aged 47, died, April 10

John J Shaner, Agnew, Calif, Eclectic Medical Institute, Cincinnati, 1881, aged 83, died March 20 in the Agnews State Hospital, of chronic myocarditis

Archibald McEachran @ Minneapolis, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889, aged 68, died, April 11

Arthur Henry Leary, New York, College of Physicians and Surgeons, Medical Department of Columbia College New York, 1879, aged 79, died, April 12

James Short, Evans, Ky (licensed in Kentucky in 1920), member of the Kentucky State Medical Association, aged 77, died, April 21, of pneumonia

William Alison Lumley, Ellsworth Wis, College of Physicians and Surgeons of Chicago, 1893, aged 77, died, April 9, of lobar pneumonia

Francis Marion Collier, Montrose, Calif, Denver College of Medicine, 1895, aged 76, died, March 25, of chronic myocarditis and acute nephritis

Charles Lewis Knight @ Boston, Harvard University Medical School, Boston, 1901 aged 60, died suddenly, April 18, of coronary thrombosis

Emile Claud Mervy, San Francisco, University of California Medical Department, 1883, aged 76, died, February 14, of mitral regurgitation

Alfred Hultner, Pomona, Calif, University Medical College of Kansas City, Mo, 1896, aged 67, died, March 2 of cirrhosis of the liver

Magnus Andrew Unseth, Chicago, Rush Medical College Chicago 1893 aged 66, died, May 12, of lobar pneumonia and lymphatic leukemia

Daniel E Thatcher, Dallas, Wis (licensed in Wisconsin in 1900), also a pharmacist, formerly postmaster and mayor, aged 66, died, March 17

William Henry Mahler, New York Bellevue Hospital Medical College New York, 1880 aged 80, died, April 22, of bronchopneumonia

William B Graham, New Paris, Ohio (licensed in Indiana in 1897) Civil War veteran, aged 91, died, April 30, of cerebral hemorrhage

Charles Albert Gill, Madison, Wis Rush Medical College Chicago 1884, aged 79, died, March 22, in a local hospital of uremia

Eugene O Houck, Cleveland, Western Reserve University Medical Department, Cleveland, 1900, aged 56, hanged himself, March 23

Elizabeth Edmonston, Hillsboro Ohio, New York Medical College and Hospital for Women, New York, 1895, aged 79, died, April 12

Samuel S Watkins, Owensboro, Ky, University of Louisville School of Medicine, 1884, aged 70, died, March 25, in the City Hospital

Herbert Karl Smith, Modesto, Calif, Louisville (Ky) Medical College, 1894, aged 66, died, March 1, of cerebral hemorrhage

Edwin Llewellyn Hunter, Niles, Mich, Hahnemann Medical College and Hospital, Chicago, 1896, aged 60, died, March 30

Harrison Proctor Millard, Vancouver, B C, Canada University of Toronto (Ont.) Faculty of Medicine, 1891, died in March

Frederick Charles Marlow, Toronto, Ont, Canada, University of Toronto Faculty of Medicine, 1915, aged 40, died, April 25

George A Vinson, Atlanta, Ga, Southern Medical College, Atlanta, 1881, aged 77, died, April 26, of uremia and chronic nephritis

Sterling Egbert Neblett, Southside, Tenn., University of Tennessee Medical Department, Nashville, 1891, aged 75, died, April 5

Ernest Linwood Marston, Rock Island, Ill, Rush Medical College Chicago, 1888, formerly bank president, aged 74, died, April 2

Harold Winthrop Martin @ Boston, Tufts College Medical School, Boston, 1912, aged 48, died, April 15, at his home in Milton

August Kuhn, Pflugerville, Texas, Louisville (Ky) Medical College, 1894, age 66, died, February 26, of coronary thrombosis

William A Peek, Helena, Mont., Homeopathic Medical College of Missouri, St. Louis, 1898, aged 66 died March 12,

William Jefferson Guernsey, Philadelphia, Hahnemann Medical College of Philadelphia, 1875, aged 81, died, March 30

Hansford L Walls, Nitro, W V, University of Maryland School of Medicine, Baltimore, 1881, aged 73, died, March 11

Elwin Dexter Lane @ Andover, Mass, Boston University School of Medicine, 1912, aged 59, died, March 25, of uremia

Simon Beckman, Hartsville, S C., Medical College of the State of South Carolina, Charleston, 1884, aged 71, died, May 7

Clifford Henry King, Wabash, Ind, Rush Medical College, Chicago, 1881, aged 76, died, March 16, of chronic nephritis

Bruno Francis Sandow, Berkeley, Calif, Northwestern University Medical School Chicago 1891, died March 13

Bureau of Investigation

MORE NOSTRUMS IN RETROSPECT

Condensed Reports on "Patent Medicines" Previously Dealt With in Greater Detail

The chief work of the Bureau of Investigation lies not, as many physicians think, in the preparation of articles that appear in this department of *THE JOURNAL*, but in answering the thousands of letters that are received every year from physicians and laymen asking for information on "patent medicines" and quacks. These letters show that there are certain "patent medicines" that are much more widely inquired about than others, usually because the amount of money spent on advertising ballyhoo keeps them in the public eye. About a year ago there were published in this department condensed reports of longer articles published previously on several widely advertised "patent medicines" about which the Bureau receives a large number of inquiries. The material that follows gives in condensed form statements regarding additional "patent medicines" that have already been dealt with in the past in more extended articles.

Absorbine, Jr.—This preparation was the subject of an extended article that was published in *THE JOURNAL* Oct. 25, 1913. Absorbine, Jr., is a liniment and, when first put on the market, was claimed to "remove any soft bunch without blistering or inconvenience" and to be "the only liniment known that positively cures varicose veins." As time went by, these obvious falsehoods were abandoned, but even at the time of the Bureau of Investigation's article it was still sold under the inferential claim that it would cure rheumatism, neuralgia, headache, varicocele, orchitis, toothache, corns, gopher, elephantiasis and several other conditions. Absorbine, Jr. was analyzed in the A. M. A. Chemical Laboratory and the chemists reported that it was a clear, bright green liquid having a strong, penetrating, mint-like odor and seemed to be an acetone extract of some plant, probably wormwood, with the possible addition of some oil of sassafras and oil of menthol. The 1935 advertising of Absorbine, Jr., is much more restricted and conservative. It has been especially featured in the past year or so as a remedy for "athlete's foot" and insomnia.

Alka-Seltzer—This "patent medicine" put out by the Miles Medical Company of Elkhart, Ind., was dealt with in *THE JOURNAL* Nov. 12, 1932. At that time the entire trend of the advertising was to give the impression that Alka-Seltzer was a mild, effervescent, alkaline preparation, although, in fact, the stuff was essentially aspirin. From the analysis of the A. M. A. Chemical Laboratory, it appeared that persons following the directions to dissolve two tablets of Alka-Seltzer in a glass of water got nearly 9 grains of aspirin and nearly 1 grain of salicylic acid with their mixture of citric acid and baking soda. Those who did as was suggested and took sixteen such tablets a day would get over 70 grains of aspirin and 6 grains of salicylic acid in twenty-four hours. Recent (May, 1935) radio broadcasting advertising still plays up the alleged antacid features of Alka-Seltzer. It incidentally refers to the fact that the stuff also contains, as the broadcast ballyhoo puts it, an "acetylsalicylate." Not one non-medically trained person in ten thousand, of course, knows that an "acetylsalicylate" refers to aspirin. If one reads the small type on the trade package of today, he may learn that Alka-Seltzer, when dissolved in water, produces "Acetyl Salicylate of Sodium" described as "a salt of Aspirin." Nowhere, however, is any hint given as to the amount of aspirin present, and it is difficult to avoid the conclusion that the vast majority of people who take Alka-Seltzer are still quite ignorant of the fact that they are taking aspirin.

Bromo-Seltzer—This preparation was dealt with in *THE JOURNAL* of Feb. 10, 1906. According to the analysis of Bromo-Seltzer published at that time, an average dose of the preparation—a teaspoonful, weighing about 76 grains—would contain potassium bromide, 7 grains, acetanilid 3 grains and caffeine, 0.8 grain. In the same issue of *THE JOURNAL* a Nebraska physician reported a case of poisoning from Bromo-Seltzer.

The most powerful drug in Bromo-Seltzer is acetanilid. The dangerous potentialities of acetanilid make the indiscriminate use of "patent medicines" containing this drug a serious menace to the public health. Cases of death, collapse, chronic poisoning and "habit" have been reported in medical literature from the use of Bromo-Seltzer. Sollmann in his "Manual of Pharmacology" (4th edition, 1932), in writing on the use of acetanilid in proprietary headache powders, states that they have "repeatedly produced acute and chronic poisoning" and that their continued use by persons with a predisposition to the drug "has occasionally caused the development of a drug habit, with craving and withdrawal symptoms." Sollmann points out that in chronic acetanilid poisoning there is a destruction of the red blood corpuscles, with blueness of the skin, heart weakness and "progressive mental and physical debility."

Converse Treatment for Epilepsy—This preparation has been dealt with in *THE JOURNAL* at various times. The first article appeared April 24, 1915, the second Dec. 2, 1922, and the third Dec. 19, 1931. The first article contained the chemists' report, showing that the Converse Treatment was another one of the bromide mixtures and that a person taking the stuff in accordance with the directions would get an amount of bromide equal to 58 grains of potassium bromide daily. One H. E. Sanderson seems to have been the head of this mail order quackery. The names of victims or, in the parlance of the medical mail order faker, the "sucker list," has, in the past at least, been obtained by the Converse concern by writing to the mayors, presidents of city councils and justices of the peace of small towns, as well as to teachers. These people were offered a premium, such as a small dictionary for the names of four epileptics, a fountain pen for the names of three, a cook book for the names of two, or a song book for one.

Hayes Asthma Treatment—The alleged asthma remedy of P. Harold Hayes of Buffalo, N. Y., was the subject of a brief article in *THE JOURNAL* of Oct. 2, 1909, giving the results of an analysis made by the Pharmaceutical Institute of the University of Berlin. The treatment is apparently a combination one, consisting mainly in the administration of iodides, together with a cough remedy, some iron and quinine, with, of course, the inevitable laxative. The six drugs used in the treatment were described and reported on as follows: *No. 763*—Purgative pills, having as the active principle, jalap. *No. 769 A C*—A syrup containing 67 per cent of iodine combined as potassium sodium and ammonium iodides. *No. 781*—A cough medicine containing about 65 per cent of oils of turpentine and peppermint emulsified and sweetened with syrup. *No. 808*—Capsules containing about 1½ grains of quinine sulphate. *T I Q*—Potassium iodide, a little wine and a small percentage of hydrochloric acid. *T II Q*—A liquid to be taken three times a day and found to contain iron in the form of iron peptonate.

Hunter's Epilepsy Treatment—This piece of mail-order quackery exploited by LaFayette M. Hunter, M.D., of Little Rock, Ark., under the trade name Dr. Hunter Laboratories, was dealt with at some length in *THE JOURNAL* June 19, 1926. At that time it was stated that there was associated with Hunter one H. S. Brevoort, M.D. Both Brevoort and Hunter had previously operated quack advertising offices elsewhere. Later, Brevoort's name failed to appear in connection with Hunter's mail-order quackery, but did appear in connection with a testimonial for the Hunter product. Hunter used to emphasize in his advertising that his preparation would stop seizures from the first day that it was used. The Hunter 'remedy' came in the form of a white powder in colored capsules. When analyzed in the Chemical Laboratory of the American Medical Association, the stuff was found to be about one-fourth phenobarbital (luminal) and three-fourths milk sugar! Later the Hunter concern seems to have established a subsidiary company known as the Dexo Chemical Company, putting out another alleged remedy for epilepsy under the name "Dexo." This, when analyzed by the A. M. A. Chemical Laboratory, was found to be a bromide mixture.

Lane's Asthma Treatment.—D. J. Lane of St. Mary's Kan., has for some years put out a mail-order patent medicine for asthma. The preparation was analyzed some years

ago in the A M A Chemical Laboratory and a brief article appeared in THE JOURNAL May 10, 1919, giving the essential facts. The chemists reported that each dose of Lane's preparation contained approximately $2\frac{1}{2}$ grains of calcium iodide, giving a daily dosage equivalent to 11.3 grains of potassium iodide.

Tums.—This preparation, put out by the A H Lewis Medicine Company of St. Louis, was the subject of a brief article in THE JOURNAL May 23, 1931. It was there brought out that analysis indicated that Tums was apparently nothing more marvelous than sugar and chalk flavored with peppermint.

Correspondence

ATTITUDE OF BRITISH MEDICAL ASSOCIATION ON EXTENSION OF SICKNESS INSURANCE

To the Editor—I must protest against the statement which appears at the beginning of the London Letter in the issue of THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION for March 30. The sentence to which I refer is as follows: "In 1930 when this party was in power, the British Medical Association brought forward a scheme for a state medical service for the whole population." I wish to state emphatically that the British Medical Association has never brought forward any such scheme. It is true that we have advised the extension of the present national health insurance system to include first the dependents of all the existing insured persons and others of a like economic status and secondly, the provision of a consultant service and all necessary specialist and auxiliary forms of diagnosis and treatment, for this defined section of the community, but we have never advocated the inclusion within the ambit of the national health insurance scheme of that section of the population of status above that of the present insured.

The British Medical Association believes that there is a large section of the community which, unaided, is unable to provide for adequate medical attendance and it is for this section that it is considered the national health insurance system should provide, but the association also holds the view that there are many for whom no state provision is necessary as they are well able to provide for themselves.

G C ANDERSON M D, London
Medical Secretary, British Medical Association

MEDICAL LICENSURE

To the Editor—In table 10 of the extremely valuable statistics of medical licensure presented in THE JOURNAL, April 27, and still more markedly in the map appearing on page 1513, the merit so well deserved by the various state examining boards for their efforts to exclude the more poorly or the unqualified candidates from the practice of medicine seems to be very unfairly assigned to certain states, whose legislatures appear to have done their utmost to make nugatory the endeavors of their own examining boards.

Thus for example this state of Maine, where I reside, is indicated on the map unshaded, indicating that it licenses no osteopaths, no undergraduates, and no graduates of unapproved schools; on the other hand the state of Massachusetts, in company with three others is shown in black, having in 1934 licensed twenty-one osteopaths and fifty-four other undesirable nondescripts, out of a total of 216 such applicants.

But then it is well within my knowledge that here in Maine a large number of osteopaths and others of that type (chiropractors and so on) are actually carrying on a perfectly legal practice, claiming to be legally qualified to do everything in

the way of medicine, surgery and obstetrics permitted to regular practitioners. These men have not been passed on at all by our state medical boards, nor is there in this state any basic sciences board, their actual qualifications are pretty well indicated by Etherington's paper on osteopathy and licensure on page 1549 of the same issue of THE JOURNAL, and doubtless any examination to which they have been submitted is as farcical as are the institutions from which they graduated.

If Massachusetts, represented by its state examining board, is unduly lax, it may perhaps be defended on the ground that half a loaf is better than no bread. It does at least submit the nondescripts it cannot exclude to some kind of examination actually rejecting 141 for seventy-five that it passes, some of the 141 doubtless coming to Maine, with possible results such as an Etherington might "shudder to envisage."

So, after all, I would prefer to see a lighter marking for Massachusetts and others, and a black mark for Maine and others in spite of the good intentions of state boards which 'ging sae far a' glae.'

WILLIAM R. TYMMS, M D, Port Clyde, Maine.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

RENAL OR NORMOGLYCEMIC GLYCOSURIA

To the Editor—Kindly advise me as to the diagnosis in the case of W R C a white man aged 24, a graduate engineering student weighing 156 pounds (70 Kg). His maternal grandfather is living at 81 but has been diabetic for twenty years; he has never been on insulin but the condition is proved by high blood sugar and he has survived by dieting and a strong will power to resist overeating. One sister, two years younger as a college student found much sugar in the urine and for the past three years in two hospitals and in private practice has been diagnosed as having a low renal threshold and possibly potential diabetes but the blood sugar has never been above normal except in one single hour hospital test and the accuracy of the test has been questioned. There is no other relevant family history. The patient has always been a heavy eater; he eats but does not crave sweets and eats three meals. He eats little breakfast but the evening dinner is more than the other two meals combined. He has eaten much meat and had two glasses of sweet milk at each meal for many months and before hurrying to school after arising late frequently makes a breakfast of cakes. January 18 he ate one Bahy Ruth at 5 p m in addition to his regular diet. January 19 at breakfast he ate two egg sandwiches. For lunch he had a large piece of roast beef, French fried potatoes, peas, fried corn, four large biscuits, rice pudding, large servings of all and two glasses of sweet milk. Three hours after this meal three tests of the urine were made. The specific gravity was 1.025 and Benedict's test was decidedly green with a yellowish tinge. At 6 o'clock it was still green but lighter. For dinner the patient ate a large steak, French fried potatoes, stewed corn, two hot biscuits and two glasses of milk. Two hours after this the urine was reddish yellow and three hours later pea green with Benedict's test. January 20 the patient arose at 6 a m and drank a glass of water. Examination of the urine gave negative results. He drove 58 miles but had no other exertion, and rested for thirty minutes on the bed and a sugar tolerance test was begun with 100 Gm of dextrose. The fasting sugar was 120 mg per hundred cubic centimeters. No test of the urine was made. At one-half hour the sugar was 152 mg with a trace in the urine. At one hour the sugar was 97 mg. No specimen of urine was taken. At two hours the sugar was 81 mg and the urine was normal. The patient drops off to sleep readily when sitting around but as a student he may not get enough sleep. He has a voracious appetite and drinks an enormous amount of water estimated at from three quarts to a gallon a day. No itching eruption or boils are present but he has drunk a great deal of water for three or four years and nearly always gets up at night to void sometimes two or three times but at times sleeps all night without interruption.

M D Virginia

ANSWER.—The diagnosis in this case would seem to be renal or normoglycemic glycosuria. The fasting blood sugar of 120 is a high normal value, but the subsequent blood sugar values are quite normal and the test as a whole should be interpreted as that of renal glycosuria. Supporting this diagnosis is the fact that a sister apparently has a similar condition. The condition of low renal threshold is distinctly hereditary.

The associated voracious appetite and the large amount of water consumption raise the possibility of organic disease of

the diencephalon. Brain tumor should be excluded. The possibility of a previous encephalitis should be considered. Many cases of diabetes insipidus are treated effectively by a procedure described by Francis M. Smith, "Diabetes Insipidus Treatment by Intranasal Insufflation of Posterior Lobe Pituitary Powder" (THE JOURNAL, March 3, 1934, p. 660).

THROMBOPHLEBITIC EDEMA

To the Editor—A man aged 40 was operated on six years ago for hernia and hemorrhoids with an uneventful recovery until he was allowed to go home which was on the eighteenth day when phlebitis developed in both legs which kept him in bed for eighteen weeks. Following this he had no particular pain but had swelling in both legs more marked around the ankles but extending nearly up to the knees. This was controlled by elastic bandages. In the spring of 1933 besides the existing edema he had indurated painful and tender areas about 2 cm wide by 6 cm long with no apparent superficial reddening in the lower part of both legs (extending about 2 cm deep). These areas vary in size but have never completely disappeared. To August 1933 two painful small ulcers (1 cm in size) developed on the anterior surface of the left leg at the level of the junction of the lower and middle third which eventually healed in about two months with boric acid ointment and sunlight treatment. About six weeks ago apparent thrombosis of some small superficial vessels developed below the left external malleolus. These had the appearance of small pinheaded elevations. This was accompanied by severe pain and eventually broke down to form a small painful ulcer which is slowly healing up. The area around this is also very tender and painful especially while walking. During the day and night he complains of pain in both legs. There are no varicosities of the superficial vessels to be seen. In August 1933 glycosuria was discovered which was controlled by dieting. The blood sugar three months ago was 115 mg per hundred cubic centimeters. Other constituents of the blood are normal. The urine otherwise is normal. The blood Wassermann reaction is negative. Because of financial considerations the patient is compelled to continue working (he is a grocery store clerk) which is naturally aggravating his condition. What line of treatment would you advise following without having to put him to bed? Please omit name.

M D New York

ANSWER—The bilateral thrombophlebitic edema induration and ulceration of this patient is probably maintained in a subacute or recurring state by some low grade infection. This infection may be found in the usual foci, such as the teeth, tonsils or prostate, but more often in the edematous, indurated tissues themselves, which harbor bacteria readily and respond with acute flare ups following slight trauma, chilling or trivial respiratory infections. Attacks of phlebitis and periphlebitis, if near to the skin, readily break it down and form painful indolent ulcers, which are often resistant to treatment. After eradication of the infected foci an attempt should be made to put the inflamed tissues at rest. When rest in bed is impracticable Unna's paste boots are helpful in reducing the swelling and pain. Small doses of x-rays, 100 roentgens three times at ten day intervals, may be beneficial. As the persistent edema is injurious to the tissues an attempt should be made to reduce it by elevation at night, restriction of fluid and salt intake, and 5 Gm daily doses of potassium chloride. The treatment of these late cases of thrombophlebitic edema is difficult and sometimes unsuccessful. Better results may be obtained at the onset of the thrombophlebitic edema (de Takáts, Geza. The Management of Acute Thrombophlebitic Edema. THE JOURNAL, Jan 7, 1933, p. 34).

PTYALISM DURING PREGNANCY

To the Editor—I desire some information about the treatment of ptyalism during or following pregnancy. A patient aged 36 years went through her second pregnancy four years ago. She had considerable nausea during the early months and a very distressing ptyalism during the last five months. The saliva a clear thin fluid amounted to from 400 to 600 cc a day. This symptom disappeared with the advent of labor. One year ago she had a cold or influenza which lasted about a week, when the ptyalism returned and has lasted ever since. There is no excessive flow of saliva during the day but in the morning when she awakes the mouth and throat are filled with a thin lumpy liquid which she cannot swallow without vomiting. This disappears when she eats breakfast. The patient leads a normal life does her own housework and works a little in a store. She is not nervous and there is no domestic or other sort of worry. Please omit my name.

M D Indiana

ANSWER—Ptyalism is a complication of pregnancy that is hard to cure, disappearing usually when quickening occurs but persisting in rare cases, up till delivery or even two or three months thereafter. It may recur in successive pregnancies.

Ptyalism has also been known to occur during menstruation; it can act vicariously for menstruation and it has been known to be present in cases of chronic endometritis, myometritis (Tamburini), retroflexio uteri (Schauta), amenorrhea (Simpson) and cancer (DeWees). The causes of salivation, both in pregnancy and outside of pregnancy, have not been deter-

mined, the various theories for the cause of toxemia having been invoked, such as reflex, toxic, neurohysterical and endocrinopathic.

In the case referred to the symptoms do not indicate a true ptyalism. Since mercurialization can be eliminated, some disorder of the teeth, gums or sinuses should be sought for. Stomatitis, thrush, parotitis and inflammation of the submaxillary gland (and stone) should be considered. Since DeWees found ptyalism in a case of genital carcinoma and since the sialorrhea can be hormonal, a special study of the ovaries would be in order. Treatment of course must be aimed at the cause if it can be found, otherwise local washes and general measures devoted to improving the health and to curing a possible avitaminosis are recommended.

X-RAY OF LUNGS FOR SILICOSIS

To the Editor—I would like some information on the technique of taking roentgenograms of the lungs. I have been told that cases of silicosis may be overlooked if taken with a 30 milliamperage machine and that in order to obtain satisfactory plates more milliamperage must be used. Is there anything to this? I should also like to know where to obtain a good book on chest roentgenology especially one covering silicosis. Please omit name and initials.

M D Indiana

ANSWER—Chest films made with a 30 milliamperage machine are considered entirely satisfactory for the diagnosis of silicosis. Thousands of men are being examined every year with 30 milliamperage machines installed in factories, and the results are entirely dependable. Comparison of films made in a tenth of a second with a 100 milliamperage broad focus tube, at a distance of 5 feet with films made in a third of a second with a 30 milliamperage tube at the same distance, the other factors being the same, show but little in favor of the faster exposure. The additional details furnished by the smaller focus of the 30 milliamperage tube more than compensate for the briefer exposure with the 100 milliamperage machine, which must necessarily use the larger focus. At an expense that is altogether out of proportion to any advantage gained, it is possible to use 1,000 milliamperes or even more and to obtain x-ray films in a small fraction of a second. Five hundred milliamperes at a distance of 6 feet will give a beautiful film of the chest in a thirtieth of a second but after all, its detail is so little better than that obtained by a 30 milliamperage tube in a longer time that it is difficult to find justification for the expense of the more elaborate apparatus unless the work is being done in a large institution specializing in lung diseases. Of course, the more rapid exposures are calculated to minimize the blurring in the vicinity of the lung roots and the descending branches of the lung tree resulting from the pulsations of the heart, but these pulsations disturb fine detail only for a short distance and in the remainder of the lung it would be extremely difficult to overlook silicosis.

Good books and articles on chest roentgenology in silicosis are the following:

Wessler and Jaches. Clinical Roentgenology of Diseases of the Chest. Troy, N. Y. Southworth Publishing Company.
Sante, L. R. The Chest Roentgenologically Considered. New York: Paul B. Hoeber Inc. 1930.
Overland, Walker. The Radiography of the Chest. London: William Heinemann Medical Books Ltd. 1928. two volumes.

All of these have sections relative to silicosis.

Pancoast H. K. and Pendergrass E. P. Pneumoconiosis (Silicosis). A Roentgenological Study. New York: Paul B. Hoeber Inc. 1926.

The following articles are also valuable for reference.

HAZARD IN USE OF BRONZE POWDER

To the Editor—Several girls were put to work in a printing shop gilding the lettering on covers of a catalogue. The gilt is dusted on recently printed letters. The girls are given small occasional jobs of this nature and do it by hand using cotton dusters. The powder more or less fills the air in the room which has no particular ventilation excepting the usual doors and windows. Friday and Saturday this work was done. On Saturday afternoon three girls complained of headaches and at about midnight one called me in still having the headache also a raw feeling in the trachea and a temperature of 101.4 F. Examination demonstrated a considerable coating of gilt powder in the nose and in one spot a reddened area which looked as if it had been bleeding though there was no history of this. In the mouth there were three teeth with swollen gums (two central incisors and a left canine) which looked like Vincent's angina and a blue line along the margin though this line was not very definite. I read poisoning of course entered my mind but not convincingly. She had not worked long in the shop so type would hardly be accountable. There were no other symptoms pointing to lead or nervous or abdominal symptoms. Striking was the statement that the stool was filled with gold. (Her mother said she resembled the goose that laid the golden egg.) Objection to further was the statement that the teeth were brushed almost daily and the other teeth indicated this in their clean condition. Vincent's organisms were not found. I should like to know what the ingredients are of such gilding powders. The one used was made by the Hill International Printing Ink Corporation supposed to be in Chicago though there was no address on the box. Another powder (brand) was also used to some extent, the name of which was not obtained. Rest a mouth wash (perborate) and a cathartic cleared up the symptoms entirely so the patient went to work on Monday. There is however some excitement among the employees and I should like to allay it if possible or take precautionary measures if that is necessary. If there were but one case I would consider allergy probable. I do not believe there would be lead or mercury. Please omit name. M D Illinois

ANSWER—Bronze powders frequently have been suspected of causing occupational diseases but most of the available evidence is to the contrary. In the past more than at present, lead as an impurity in the metals making up these powders has been encountered in quantities theoretically sufficient to induce lead poisoning. Gilding powders are ordinarily made up of copper, zinc and aluminum, more than 75 per cent being copper. Dust arising from exposure to gilding powders might in time produce increased fibrosis of the lungs, but the danger is negligible compared with that from silica and from silicates. The mechanical action of bronze powders may lead to the irritation of the respiratory passages but the quantity of damage is surprisingly low when considered in connection with the amount of powder sometimes deposited along the mucous membranes.

Some of the various fixing agents used to bind the gilt to the object being gilded are more likely sources of immediate irritation. Various types of sizings or varnishes are used for this purpose. A common one is a linseed oil varnish, which may contain naphtha solvent naphtha, linseed oil small amounts of lead and manganese. At times amyl acetate or similar agents enter into these fixatives. The combination of minor chemical irritation from the fixative plus minor mechanical injury from the gilding powder probably account to a full extent for the condition described. Subsequent infection of the respiratory tract undoubtedly played a part. Under ordinary circumstances this type of occupational injury may be regarded as of relatively minor significance. However if this operation is carried out near printing presses some consideration should be given to the possibility of irritation from a press cleaning material which commonly is naphtha, and some printing inks which sometimes contain vaporable irritating constituents.

ACETYLCHOLINE IN BENZENE POISONING

To the Editor—The use of acetylcholine for the prevention of death due to the inhalation or absorption of benzol, or benzene has been discussed in some of the technical journals during the past year or so. It so happened that we are using benzene at some of our operations and we should like authoritative information regarding the use of this drug its effects, and results produced to be passed on to the medical men at our plants. If you do have any information available we shall appreciate your help.

C L JONES Wilmington Del
Safety Engineer, Hercules Powder Company

ANSWER—Lately several articles have discussed the many types of actions produced by acetylcholine on animals. Among other properties it influences the autonomic nervous system, leads to vasodilatation and a fall in blood pressure sometimes with a secondary rise, slows the heart rate, and produces hyperglycemia. However, in man similar activities have not developed to an equal extent. Ellis and Weiss state that, after the intravascular injection of acetylcholine in man apparently this substance is inactivated in the capillaries and loses its capacity to induce changes. They continue. It is improbable that acetylcholine acts as a general hormone in the human body and unless

it acts differently in disorders of the arteriolar system it cannot be considered a useful therapeutic agent." In benzene poisoning two features are (1) the loss from the blood of many of those chemical bodies that provide protection against bacterial action with the result that an excessive proneness to infection exists (infection nearly always is the direct or contributory cause of death) and (2) the presence of a leukotoxin that tends to deprive the body of the presence and functional activity of leukocytes. At the same time there result from an action of the benzene on the bone marrow large numbers of premature red cells in the blood stream which are possibly of limited functional capacity. It is difficult to believe that acetylcholine may eliminate such results of benzene toxicity. Possibly some manifestations of benzene poisoning may favorably be influenced by this choline but no reason is known why this agent may be regarded as of any remarkable value in "the prevention of death due to inhalation of or absorption of benzene," as noted in the query. Moreover, Kahlson has stated that "acetylcholine has all the properties of a potential poison." Acetylcholine must be considered as still being decidedly in the experimental stage. It has not been recognized by the Council on Pharmacy and Chemistry as acceptable for New and Nonofficial Remedies.

PURPURA AFTER ARSPHENAMINE

To the Editor—I have a patient with syphilis whom I have been treating with bismuth arspenamine sulphate for the last three months. Following the last injection a few purpuric spots appeared beneath the elbows and he had some bleeding from the gums otherwise he looks and feels all right. Stokes in his latest edition on syphilis mentions the fact that this symptom is a serious precursor of a more violent blood destruction. Now what I want to know is whether I can use any other arspenamine derivative or should I stop all such treatment and stick to preparations of bismuth and mercury? Stokes mentions the severity but says nothing about treatment of the condition. Please omit name. M D, Connecticut

ANSWER—It is inadvisable to continue the use of any arspenamine preparation or derivative including bismuth arspenamine sulphate after the appearance of purpuric spots and hemorrhage from the gums. The precise significance of these symptoms can be to some extent controlled by an immediate examination of the blood smear for signs of bone marrow irritation and injury.

Stokes discusses in full on pages 478-481 in the latest edition of "Modern Clinical Syphilology" the warnings of injury to the hematopoietic system giving full details of treatment, including the precise statement: purpura and extensive capillary hemorrhage after an injection of an arspenamine is a sign of the gravest import, and should be a warning never to repeat this form of treatment' (page 478). Again, on page 480 he says "The treatment of the hematopoietic group of complications consists first in immediate and probably absolute discontinuance of an arsenical when even traces of purpura have appeared in the patient." The only form of treatment not mentioned by Stokes, since it postdates the publication of the second edition, is the possible use of leukocytic cream as recommended in agranulocytosis by Strumia, for example.

CONTROLLING SIZE OF INFANT—USE OF POTASSIUM NITRATE TO REDUCE LIBIDO

To the Editor—1. There is a prevalent belief among women that pregnant women need not and should not have big babies and that the doctor is to blame if it is over 7½ pounds (3400 Gm.) That opinion was also stated today over the radio by psychologist Frank Payne. What is the consensus? 2. In a girl's college in New Jersey, nitre is given daily in some foods ad nauseam to some pupils the object being as stated to keep down passion. And the statement is made that this drug is given in other colleges for the same purpose. Please inform me whether nitre is of real value for that purpose and if it is safe to continue its use indiscriminately, year after year.

M D New Jersey

ANSWER—1. The size of a new-born baby is by no means under the entire control of its mother or of the physician who gives the mother antepartum care. To a moderate extent the size of a baby may be kept down by the mother if she is placed on a restricted diet. However, the size of a baby depends much more on hereditary factors than on diet. Hence a physician cannot be blamed if he delivers a large child unless the baby is monstrously large. If a physician recognizes that for some known (diabetes) or unknown reason a child in utero appears to weigh more than 4,000 Gm he is justified in inducing labor. However, it would be pernicious practice to induce labor in every case in which a baby appears to be over 3,400 or 3,600 Gm. Furthermore in many cases it is notoriously difficult to estimate the weight of a child in utero except with

the aid of roentgenograms. Furthermore, unless the roentgenograms are taken under standardized conditions, many errors will be made.

2 Potassium nitrate has practically no effect in reducing passion. Since the drug is used as a diuretic and as a diaphoretic and since it may produce gastro-enteritis, it is obvious that long continued use of it may result in harm. It should certainly not be given indiscriminately to a group of girls even for brief periods. It might be interesting to find out on whose authority the college in question forces girls to take the drug.

PEYRONIE'S DISEASE OR PLASTIC INDURATION OF PENIS

To the Editor—Recently a man aged 48 consulted me with the complaint that for the past year and a half he has had occasional shooting pains from his left side down into the left side of the penis. The pains have been much less during the past six months, but he has noticed that when he has an erection the organ bends to the left almost to a 30 degree angle. He has also noticed that the left side seems to be smaller and denser in consistency than the right side. During an erection he experiences considerable pain and intercourse is almost impossible. The condition is apparently becoming worse except for the pain and he of course is desirous of relief. Examination revealed a fibrosis or thickening of the corpus cavernosus on the left side. It has a solid consistency and one can see how that side would be shorter during an erection. His past history is negative. Cystoscopy did not reveal anything abnormal. The neurologic examination also gave negative results. The Wassermann reaction was negative. Any suggestions as to treatment would be greatly appreciated. Please omit name.

M D Wisconsin

ANSWER—From the history it is evident that the patient has a so-called Peyronie's disease, sometimes called plastic induration of the penis, or fibrous cavernitis. In view of the fact that the etiology of this condition is unknown, no specific treatment is at hand. On the theory that this may be due to focal infection, careful search for infection of the teeth, tonsils and sinuses should be made, and likewise it is important to massage the prostate and seminal vesicles and to examine the expressed fluid for the presence of pus. If foci of infection are found they should be treated accordingly.

The treatment consists of soaking the organ in hot water two or three times a day, followed by mild massage of the thickened area. It is desirable in some cases to use the official U S P iodine ointment made with a vanishing cream base instead of the U S P base. Administration of potassium iodide, from 0.65 to 1 Gm three or four times a day, seems to help in some instances. Application of diathermy to the thickened areas occasionally produces great improvement. Roentgen treatment and radium treatment have been advised. Their value is somewhat doubtful.

Surgical treatment offers little in the way of cure and is often followed by a prompt recurrence, often in an aggravated form.

MUCUS SECRETION IN TUBERCULOSIS

To the Editor—A man aged 62 has tuberculosis of some twenty five years standing, always of the subacute variety. Now all signs of active tuberculosis are absent (temperature and pulse are normal, sputum is negative, blood pressure is 120 systolic, 80 diastolic) except an asthmatic condition which appears to be due to a secretion of thick tenacious mucus which he expectorates. At times he coughs up mucous casts of the bronchi. I have tried all the usual expectorants but they soon lose their effectiveness and when given in large doses they disturb his digestion. I am afraid to give iodides for fear they will cause absorption of the scar tissue in his lungs. He is haunted by a fear that some time he will die of suffocation before medical aid can be obtained. Epinephrine gives temporary relief but later the condition is aggravated. On several occasions I have resorted to ether inhalations to relieve the spasm of the bronchi and stimulate the secretions. Aside from the distressing condition the patient is in excellent health and attends to his business during the day. Any assistance you can give me will be gratefully received. Please omit name.

M D California

ANSWER—This condition is one that not infrequently develops in advanced pulmonary tuberculosis when there has been extensive involvement with marked regression. The results of such healing leave several types of pathologic change in its wake. There is a variable degree of bronchiectasis, usually a marked emphysema in the clearing tuberculous tissue and, as the function of the lung diminishes, an active emphysema in the remainder of the lung. There comes a time when there is not enough healthy alveolar surface to aerate the blood so that a distressing dyspnea sets in, following any type of exertion or when there is otherwise any encroachment on the active alveoli. In this case it may be due to a plugging of bronchi as suggested or to an insidious inflammation that sets in from time to time as a result of infectious agents spilling over into the relatively normal tissue.

To relieve the mucus it seems that most measures have been tried. There need be no fear of trying iodides, in moderate dosage, especially if alternated with other expectorants for intervals of three or four weeks. Sometimes "coramine" will give temporary relief.

The new inflammations that develop can be alleviated only by rest. The time usually comes, however, when the hearts of such patients become inadequate for the load and there results a myocardial weakness that, near the end, is signalized by an ankle edema. Before this comes on, however, the patient's condition may be made more comfortable in the attacks by use of the oxygen tent.

FOURTH LEAD IN ELECTROCARDIOGRAPHIC TRACING

To the Editor—Will you please outline the accepted method of taking the fourth lead in electrocardiographic tracings, with special reference to the standardization to be employed in taking the fourth lead. Please omit name.

M D., New York

ANSWER—The use of lead 4 is so recent that a uniform technic has not been definitely established. However, the essential principles are now well known. Some of the details can be obtained by reference to the paper by C. C. Wolfarth and F. C. Wood in the *American Journal of the Medical Sciences* (183:30 [Jan.] 1932) and that by L. N. Katz and Milton Kassin in the *American Heart Journal* (8:595 [June] 1933). It has been accepted that the lead from the precordium is more important than the other lead. It is preferable to utilize bony landmarks for the chest lead, since it permits the taking of repeated curves from the same spot. The technic employed by Katz and Kassin is as follows:

With the patient on his back, one of the flexible tin electrodes (25 by 5 cm.), made of the same material as the sort used in diathermy, is applied at the level of the fourth interspace, just to the left of the sternum, with the long axis of the electrode parallel to the interspace. To this is attached the right arm terminal of the electrocardiograph. The other tin electrode is placed on the left leg and attached to the left arm terminal. The skin resistance should be kept low. The site of the chest electrode is shaved when necessary and the skin over the region cleansed with alcohol. A warm paste of flour and concentrated salt solution is spread over the electrodes before they are applied to the chest and leg. Adhesive tape is used to keep the electrodes in position. Care is taken to insure close application of the electrodes to the skin. The string tension is adjusted so that 1 millivolt gives a deflection of 1 cm. Care should be taken that the electrodes are polished, that the copper terminals soldered to the electrodes are clean, and that no salt solution gets on the solder.

BURN OF MOUTH

To the Editor—A boy aged 4 years by accident turned the spout end of a hot water kettle into his mouth as soon as the hot water scalded his mouth he screamed and some of the water entered his pharynx and no doubt his larynx before he could spit it out. As his mouth and throat were swollen greatly and he had a fever I treated the mouth with ephedrine sprays and also gave atropine sulphate to lessen the secretions in the mouth. Along with the foregoing he was treated prophylactically for any pneumonic condition that might develop which did not show up until the fourth day in the hospital. Since I could not find anything in the literature about such a case I would appreciate it if you would please let me know if the treatment given was correct and what else could be done in this case and in similar ones. Please omit name.

M D Canada.

ANSWER—The information at hand merely permits one to surmise that the case was one of a burn of the first degree of the tissues of the mouth and pharynx with probable involvement of the larynx. The treatment was, no doubt, quite correct and probably everything was done to prevent the development of pneumonia, unless the pneumonia developed as a result of aspiration due to abnormal function of the larynx and pharynx. When such conditions in these parts make aspiration into the lungs inevitable, feeding should be carried on extra-orally.

LOCAL ANESTHESIA IN ASTHMA

To the Editor—What is the safest local anesthetic for nose and throat procedures in allergic asthma? Kindly omit name.

M D New York.

ANSWER—Untoward effects from the use of the usual substances for local anesthesia in allergic asthmatic conditions are seldom observed. Various concentrations of cocaine may be applied to the nasal or sinus mucous membrane. Infiltration of the mucosa or nerve blocking may be carried out with 1 or 2 per cent procaine hydrochloride or similar solutions.

Minnesota January Examination

Dr E J Engberg, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held at Minneapolis, Jan 15-17, 1935. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Forty-one candidates were examined, all of whom passed. One physician was licensed by reciprocity and one by endorsement. The following schools were represented:

Book Notices

The Nervous Patient: A Frontier of Internal Medicine. By Charles Phillips Emerson, M.D. Research Professor of Medicine Indiana University Indianapolis. Cloth Price \$4 Pp 453 Philadelphia & London J B Lippincott Company 1935

On page 279 the author says 'This is not a textbook on psychiatry but one on internal medicine. In the former specialty we are quite untrained.' In spite of this deficiency, which makes itself known in many places in the book, the present volume supplies a need that has been noted as significant for years. It provides the general practitioner with a volume giving the facts in systematic form of those conditions affecting patients coming to him which lie particularly in the sphere of neurology and psychiatry. There are thirty chapters, of which the first eighteen can be considered to stress organic phenomena while the last part of the book treats of the so called functional disorders, including disorders of sleep and disorders of the personality. Those chapters concerning actual physical disease contain a great amount of systematic material, little of which deals with the form and function of the nervous system or with psychiatry. Such diseases as neuralgias, allergic pulmonary syndromes and cardiac irregularities are presented in a fashion that differs little from the manner of treatment of these disorders in the conventional medical textbook. Some of these presentations are inferior, a few superior to those found in such books as Osler's and Cecil's. Even in thyroid disease and peptic ulcer, which are now known to have a definite relationship with the patient's mental makeup, this side of the problem is minimized and their treatments are largely presented from the standpoint of conservative medicine rather than from the more modern and, in many cases, apparently the more valuable approach of psychiatry. The physician who is not well grounded in psychiatry might be led dangerously astray in dealing with an occasional case of psychogenic peptic ulcer or even psychogenic cardiac arrhythmia by leaning too much on the present work. The second part of the volume deals chiefly with the superficial aspects of the psychoneuroses. Deep therapy and analysis of these cases is not stressed. Such conditions as impotence and frigidity in women, sources of great mental diffi-

culty yet which are many times brought to the attention of the general practitioner, are sketchily handled. In this part of the book one notes short paragraphs of definitions revealing an insufficient background. The slant given to hysterias and the neuroses is largely that of the English writers on these subjects, but much material is culled from the present journal. In spite of all these deficiencies there is much material in the book to justify recommending it to general practitioners who have wondered just what they were doing when dealing with "nervous" patients. Psychiatrists will feel that a great deal of the material is antiquated and even misleading as, for example, on page 262 the use of the word Banser's for Ganser's syndrome. It might be pointed out in favor of the book that in no other recent volume has the problem of the borderline neuropathic patient been so comprehensively treated. Each topic is closed with a short bibliography and there are occasional case examples in the text.

Bee Venom Therapy: Bee Venom Its Nature and Its Effect on Arthritis and Rheumatoid Conditions. By Bodog F. Beck M.D. Cloth Price \$5. Pp. 238. New York & London: D. Appleton Century Company Inc. 1935.

This book fails in its purpose of advancing the use of bee venom because most of the evidence is uncritical. The use of bees in medicine is traced from the time of Hippocrates to the present day. The author feels that bee stings are not accepted therapy because of the professional attitude toward lay remedies (as in the case of quinine), the seasonal and rural availability of bees (commercial venom eliminates this factor), and the difficulty of using the procedure. The low incidence of arthritis in bee keepers and the tolerance of patients with arthritis to bee stings are noted. The venom is claimed to be effective through the increased oxidation (circulation) of the affected part. It is recommended in acute rheumatic fever and endocarditis, arthritis deformans, muscular rheumatism, myalgia, neuritis, migraine and many other conditions. It is stated to be contraindicated in tuberculosis, diabetes, gonorrhea and the "endocrine arthritides." The evidence presented is a hodge-podge of quotations from medical literature (principally European), from newspapers, and from testimonials of doctors, patients and bee keepers. The use of venom by applying the live bee to the patient in single and repeated multiple doses is discussed. Fatal cases of bee stings (even among bee keepers) the medicolegal aspects of bee stings, the fact that there is still much work to be done with bee venom, and the inferiority of the present commercial venoms are all noted. There is much elementary discussion of subjects usually relegated to preclinical training, the impression that the author is addressing the general public persists in the mind of the reader. The omission of the author's own case reports results in this being inadequate evidence for the use of bee venom. It is an interesting book from the historical aspect, has an extensive bibliography and is written in good style, but it is not a contribution to scientific medical literature.

Experimental Bacteriology in Its Applications to the Diagnosis, Epidemiology and Immunology of Infectious Diseases. By Dr. W. Kolle. Director of the Institute for Experimental Therapy and of the Chemical Therapeutic Research Institute, Georg Speyer Haus, and Dr. H. Hetsch, Professor at the Institute for Experimental Therapy, Frankfurt. In two volumes. Translated from the seventh completely revised German edition by Dagny Erikson. The English version incorporating further revisions edited by John Eyre, F.R.S., F.Z.S., M.D., Director of the Bacteriological Department, Guy's Hospital. Cloth Price \$16 per set. Pp. 592, 613 with 318 illustrations. New York: Macmillan Company. 1935.

This book appeared first in the early part of the century. It was based on lectures on bacteriology by the senior author, who was associated with Koch in his investigations of cattle plague in South Africa in 1897. French, Italian, Spanish and Russian versions have appeared and this is an English translation of the seventh German edition. First come chapters on the morphology and biology of pathogenic micro-organisms, on immunity, on antibodies, on hypersensitivity, on serologic diagnosis and on bacterial and serum therapy. Then begins the study of specific infectious diseases, and the microbiologic details of each "are painted in with firm strokes upon the groundwork of a picture which portrays the clinical aspects of the particular disease." Commencing with a short historical survey, the accepted microbial agent is briefly but adequately described. Then comes a consideration of the possibilities of natural infection of domestic animals, the phenomena of the human infection, its clinical course, and if fatal a

description of the postmortem appearances, whilst the necessity for detecting and isolating the microbial cause is insisted upon as the real basis of exact diagnosis. Finally comes the epidemiology of the disease, and if of epidemic importance, the routes by which it is spread, the characters of the immunity consequent upon recovery from the infection, the methods of prophylaxis and serotherapy of the disease." There is no natural dividing line between the two volumes but, curiously enough, they are treated as separate entities, each with its own pagination, chapter numbers, plate and figure numbers as well as index. This is an awkward arrangement, as the contents of each volume are not indicated either on the title pages or on the backs of the books. The illustrations, especially the many colored plates, are of great value. No really serious fault can be found with the translation. The work may be characterized as an authoritative and comprehensive survey up to the last three years or so of our knowledge of the etiology, specific diagnosis and treatment of infectious diseases and of experimental bacteriology in general, with especial emphasis on "the discoveries, theories and practice of the Koch school." It has great historical interest and should be available for the ready use of teachers and students of bacteriology and infectious diseases.

Kurzwellentherapie. Die medizinische Anwendung elektrischer Höchstfrequenzen. Von Dr. Erwin Schliephake, Privatdozent für Innere Medizin an der Universität Jena. Physikalischer Anhang von Dr. L. Bohde. Second edition. Paper. Price 10 marks. Pp. 196 with 143 illustrations. Jena: Gustav Fischer. 1935.

Three years has elapsed since the appearance of the first edition, during which period short wave radiation has aroused a keen interest in its therapeutic possibilities. That short wave therapy has actually proved superior to diathermy is now the conviction of many authoritative investigators, arrived at after independent, critical study. It was first demonstrated by Schereschewsky in America in 1926, and his labors aroused the intense interest of workers in Austro-German centers, among whom Schliephake, of the research division of the University of Jena, contributed the greatest support and the most original labors.

In the present volume the author has not only collated the opinions of various laborers in the relatively new domain of hertzian short waves but has largely contributed to it both alone and in collaboration with others. This revision of the first edition represents a commendable example of conservative and well balanced discussions on the technical, experimental and clinical phases of the subject. For those technically inclined and familiar with physics, the first section, in connection with the appended chapter by Rhode, offers a clear explanation of the nature of the hertzian waves utilized and a presentation of the physical difficulties that must be overcome to provide the most practical apparatus for short and ultra-short wave radiation. The experimental section occupies the largest part of the volume and introduces an astonishing amount of data on the electrobioelectric effects of short waves. This section is so rich in proofs of the biophysical and physicochemical changes produced together with those of their thermopenerative, physiologic and pathologic actions on cell, animal and human material as to merit the praise of the most critical reader. Schliephake himself, however, stresses that no one should offer dogmatic opinions on the present evidence because the entire problem is very complicated and involves numerous factors, which only time and greater orientation will clear up.

The clinical evidence of the value of short wave therapy is condensed to fifty-four pages but its discussion is compact and supported by concise case histories, tabulated reports, charts and especially clear roentgenograms. It reveals a large amount of clinical material of the unusual value of short and ultrashort waves in superficial and deep seated infections and inflammatory processes. The serious character of some of the conditions and the spectacular results obtained may create an unjustified skepticism by those best qualified to separate the clinical "wheat from the chaff." The author condemns the present tendency toward improper exploitation by unprincipled manufacturers and misuse by unqualified practitioners. He looks to scientific medicine to control the practice and the development of short wave radiation to insure lasting benefits. While the second edition has been materially revised and the bibliography greatly enlarged the book still lacks an index which always enhances the value of scientific contributions.

Some Functions of the Cerebral Cortex By J. E. Fulton M.D. Sterling Professor of Physiology Yale University School of Medicine Beaumont Lecturer for 1934 Beaumont Foundation Lectures Reprinted from the *Journal of the Michigan State Medical Society*, April-May 1934 Cloth Pp 47 Grand Rapids [U.S.]

This small volume comprises the thirteenth annual Beaumont Foundation Lectures which were delivered before the Wayne County Medical Society of Detroit in 1934. The lectures concern certain studies of the function of the cerebral cortex in primates. The book is divided into two chapters. The first is further subdivided into eight parts. They are: 1. Discussion of subcortical regulation of visceral functions. Intestinal peristalsis and finally intussusception result from bilateral extirpation of the frontal cortex. 2. Discussion of the cerebral cortex and its association with regulation of visceral activities. 3. Responses of the intestine to stimulation of the frontal lobes and various other parts of the cortex. Peristalsis and finally intussusception were produced experimentally by mild faradic stimulation of the supraprecentral sulcus. When the vagi were cut, no such reaction could be produced. 4. Relation of morbid hunger to lesions of the brain. The author urges further study of the motility of the stomach in traumatic crises of morbid hunger. 5. Vasomotor disturbances associated with cortical lesions and with faradic stimulation of certain cortical areas. 6. Cerebral cortex and vasomotor reflexes. 7. Discussion. 8. Summary. The second chapter also is subdivided into eight parts. Parts 1, 2 and 3 are concerned with the frontal lobes. Part 4 is concerned with the motor area and considers flaccidity, motor power and intellectual deficit. Part 5 is concerned with the premotor area and takes up spasticity and forced grasping reflex changes, motor power and ipsilateral representation and intellectual deficit. Part 6 describes frontal association areas. Part 7 presents clinical inferences. Part 8 is a summary. This book summarizes the previous work done by others as well as the work conducted by the author in his own laboratory. There is a good bibliography.

Die Liquordiagnostik in Klinik und Praxis Von Dr. Hans Demme, Chefarzt der neurologischen Abteilung des Allgemeinen Krankenhauses Barmbeck in Hamburg. Paper. Price 7 marks. Pp 205 with 96 Illustrations. Munich: J. F. Lehmanns Verlag 1935.

The author states in his preface that he aims to present a practical rather than a theoretical treatise on cerebrospinal fluid. In this he has succeeded. The book discusses the practical aspects of the subject describing the technique of examination and the cerebrospinal fluid changes in various diseases. Most of the illustrations are devoted to the normomastic reactions in various diseases. This is unfortunate as the reader is given the impression that the normomastic curve of Kafka is the most important one in the examination of cerebrospinal fluid—even better than the colloidal gold curve—an idea to which few persons acquainted with the subject can subscribe. Demme gives the p_H of cerebrospinal fluid as between 7.35 and 7.8. The upper figure is too high except when the fluid has been allowed to stand, at which time it may be even higher than 7.8 because of the escape of carbon dioxide from the fluid. In fresh cerebrospinal fluid the p_H varies between 7.4 (rarely 7.35) and 7.6. Although there is nothing new in the book it is a practical guide to the examination of cerebrospinal fluid.

The Practitioner's Library of Medicine and Surgery Volume VIII Therapeutics. Supervising editor George Blumer M.A. M.D. David P. Smith Clinical Professor of Medicine Yale University School of Medicine. Associate editor Albert J. Sullivan B.S. M.D. Assistant Professor of Medicine Yale University School of Medicine. Cloth. Price \$10 Pp 1031 with 27 Illustrations. New York and London: D. Appleton Century Company Inc. 1935.

This great system gradually approaches its concluding volume. The present volume deals with the treatment of disease by all the various methods. To this there are a great number of contributors selected because of special contributions to various phases of modern therapy. Thus diet therapy is discussed by Dr. George A. Harrop Jr., the technique of medication by Dr. Bernard Fantus, and there are also sections on hydrotherapy, climatotherapy, light and air, inhalation physical therapy, x-ray and radium therapy, biologic methods of treatment, nonspecific protein therapy, anesthesia and psychotherapy. Following this section of the book comes the remaining three fourths which is the special therapy of various types of diseases classified according to their nature and according to the specific sections of the

body. The book naturally provides a vast amount of helpful material of a practical character in the treatment of all the various conditions that may come in an ordinary practice. It is the kind of book that ought to be read carefully at least once by its purchaser and then set aside as a constant reference work in the daily problems of practice. Fortunately the book has an extended index, which yields ready reference to the material that it contains. As the authors are most of them well trained physicians with a scientific point of view, the book is remarkably free from recommendations of secret, unestablished and nostrum-like remedies.

Prépendiculaire obstétricale Par L. Devraigne chargé de cours de clinique annexe. Paper. Price 22 francs. Pp 191 with 50 Illustrations. Paris: Masson & Cie 1934.

La pratique obstétricale Par L. Devraigne chargé de cours de clinique annexe. Paper. Price 22 francs. Pp 214 with 39 Illustrations. Paris: Masson & Cie 1935.

These two books are part of a series written for medical students. In the first of the two volumes the author discusses fertilization, the pregnant uterus, the development of the ovum, the clinical examination of a pregnant woman, normal labor, presentation and contracted pelvis. In the second volume he takes up the pathology of reproduction, dystocia, puerperal infection, pathology of the new-born and obstetric operations. Readers are informed that, because of the necessity for keeping the size of the books down to a minimum only contemporary French obstetricians are quoted and unusual conditions had to be omitted. While the author successfully adhered to his first intention he frequently forgot his second plan. The first part of the second book contains discussions of numerous rarities in obstetric practice. The illustrations are few and of poor quality. The second book allots thirty six pages to the subject of obstetric operations, and one fourth of them are devoted to destructive operations. Of the thirty-nine illustrations in the entire book, eleven depict embryotomy. There are two drawings showing a vaginal cesarean section but not a single one for the classic or the transperitoneal cervical operation. For anesthesia the author prefers chloroform. He says that spinal anesthesia should be reserved for cesarean sections and for the Delmas operation. This advice is unfortunate for two reasons: first because spinal anesthesia is definitely more hazardous for obstetric patients than for other individuals and, second because the Delmas method of forcible manual dilation of the cervix should be heartily condemned as pernicious accouchement force. These books may serve a useful purpose for French students but there are more satisfactory books in English.

Pseudo Sciences and Your Three Minds By John F. Harwood. An Exposé of Astrology, Psychology, Psychiatry, Neurology, Criminology, Hypnotism, Christian Science. Cloth. Pp 137 with 2 Illustrations. New York: The Author 1934.

It must have required a good deal of courage for this writer to send his small book for review to THE JOURNAL, for even one as deluded as he appears to be should have had enough experience with the press to know that his nonsense would not be looked on with any degree of favor by any scientific group. The thesis seems to be that the author considers himself gifted with a greater mind, which is more than the usual human 'mechanical mind' and human 'conscious mind' (his synonyms for the unconscious and conscious minds of everyday psychology). He maintains that psychology, psychiatry, neurology, criminology and hypnotism are fakes and frauds and he links them with astrology and Christian science, with which he has no sympathy either. There is probably no sentence in the book to which the psychiatrist cannot take exception.

Grupo sanguíneo dos índios Guarany Por Leonildo Ribeiro, director do Instituto de Identificação W. Bernardino e M. Rolter, anthropologistas do Instituto de Identificação Rio de Janeiro. Paper. Pp 9 with 5 Illustrations. Rio de Janeiro: Imprensa Nacional 1934.

Every one of 107 Guarani Brazilian Indians examined was found to belong to group O. The authors cite Snider's study on pure American Indians (91.3 per cent group O) and Vela's study on Indians of Ecuador (95.5 per cent group O), but evidently overlooked the study by Larreta on 200 pure Indians in Peru, all of whom were found to belong to group O (Wiener, A. S. Blood Groups and Blood Transfusion, Charles C. Thomas 1935 pp 156-166). The authors have also overlooked

the study of Matson and Schrader (*J. Immunol.* 25 155 [Aug] 1933), who found that of 115 full-blooded Blackfeet Indians 235 per cent belonged to group O and 765 per cent to group A. The study by Matson and Schrader is the only exception to the general rule that pure Indians all belong to group O. Thus far these interesting observations in Indians have not been of much help to the anthropologist. It is too bad that the authors did not take advantage of the opportunity they had to examine the bloods of the Guarami Indians not only for the four Landsteiner blood groups but also for the agglutinogens M and N.

A Pathology of the Eye By Eugene Wolff M.B. B.S. F.R.C.S. Ophthalmic Surgeon Royal Northern Hospital. Cloth Price 28s. Pp. 283 with 124 illustrations. London: H. K. Lewis & Company Ltd. Philadelphia: P. Blakiston & Son 1934.

In his preface the author states that this book "is intended as an introduction to a subject whose essentials most students and ophthalmic surgeons find difficult to come by." Perhaps it fulfils that purpose. The author seems to have dealt rather superficially with the subject. In many instances the pathologic process is described all too briefly and in general terms. Only a small portion of the work will be read with interest by the student of ocular pathology. Too much space is devoted to nonpathologic phases of ophthalmology even though, as the author states in his preface, "much of that which is usually regarded as clinical ophthalmology really belongs to the Pathology of the Living." Too little that is devoted to pathology is devoted to histopathology. Thirty of the illustrations are on normal anatomy and almost all of these are from the author's "Anatomy of the Eye." There is need for a scholarly book, written in English, that will bring the subject of the pathology of the eye down to date. This book does not fill that need.

Report of the Second International Conference on Vitamin Standardization (London June 12th to 14th 1934). League of Nations Health Organisation Permanent Commission on Biological Standardization Quarterly Bulletin of the Health Organisation of the League of Nations Vol. III Extract No. 15 Paper Pp. 13 Geneva 1934.

This report is essentially a confirmation, with some revisions of the recommendations on vitamin standardization made by the first London conference in 1931. While the substances recommended as standards for vitamins A and C have been changed (to β -carotene for vitamin A and cevitamic acid [β -ascorbic acid] for vitamin C), the units formerly recommended for these vitamins have been retained and restated in terms of the newly chosen substances. The recommendations for standards and unitages of vitamins B₁ and D remain unchanged. On account of the insufficiency of our present state of knowledge concerning them, the conference has not adopted standards or units for vitamins B₂ (G) and E. The conference recognizes the desirability of expressing potency in terms of the exact amount of pure vitamin present but also recognizes the necessity, for the present of estimating potency by means of biologic tests in comparison with a standard substance. It is interesting to note that the conference recommends as subsidiary standards for vitamin A and D the standard Reference Cod Liver Oils which have been adopted for the U. S. Pharmacopeia (1934 Revision). For vitamin A a spectrophotometric test is also outlined. The report of the conference is of great interest to all who are concerned with vitamin standardization.

Diseases of Children First edition edited by Sir A. E. Garrod K.C.M.G., D.M. F.R.S. the Late Frederick E. Batten M.D. M.A. F.R.C.P. and Hugh Thursfield D.M. M.A. F.R.C.P. Third edition with contributions by 36 authors edited by Hugh Thursfield D.M. M.A. F.R.C.P. Physician Hospital for Sick Children and Donald Paterson M.D. F.R.C.P. Physician to Out Patients Hospital for Sick Children London. Cloth Price \$10. Pp. 1152 with 277 illustrations. Baltimore: William Wood & Company, 1934.

This edition has been edited by Hugh Thursfield and Donald Paterson. Numerous changes have been made from the second edition, published in 1929. Archibald Garrod, one of the original editors, has again contributed to the chapter on metabolic disorders. Several entirely new chapters are included, such as those on blood transfusion diseases of the new-born, rheumatism and tuberculosis. All the chapters have been revised. Numerous new illustrations have been included and newer therapeutic methods have been added. This continues to be the leading textbook on pediatrics by English authors.

Miscellany

THE LOST MANUSCRIPT ON OPHTHALMOLOGY BY THE THIRTEENTH CENTURY SURGEON IBN AN-NAFIS

CASEY A. WOOD, M.D.
PASADENA, CALIF.

During the winter of 1933-1934 I was working in the Vatican Library on various tasks, among them the translation of an Arabic work on the eye and its diseases—the Tadhkirat of Ali ibn-'Isa, one of the few known complete manuscript copies of which is in the library. At the same time I was having photostat copies made of any other work bearing on early ophthalmic practice not already in the McGill General Medical or the Osler Library.

I was greatly aided in these quests by the invaluable assistance of the curator of Arabic manuscripts, Prof. Giorgio Levi della Vida, formerly of the University of Rome and a widely known oriental scholar. I asked him to make a survey of the manuscripts under his charge and note any titles likely to come under the head of my research.

My ambition to undertake the translation into English, with appropriate illustrations, notes, glossary, index and bibliography of the first systematic codex on the eye and its diseases was in part due to the fact that I had been the translator of the earliest printed textbook on the same subject, the *De Oculis* of Benevenuto Grassus, Ferrara, 1474 A. D. I had long believed that some competent person ought to undertake the same task for that famous Arabic codex 'Ali ibn-'Isa's "Note-book for Oculists," which from the tenth century onward had formed part of the equipment of medieval oriental and European surgeons.

Now the best known and by far the most erudite of ophthalmic oriental scholars since Hirschberg's death is Dr. Max Meyerhof of Cairo. Moreover, while my knowledge of medieval Latin was quite equal to "Englishing" the *De Oculis*, my studies of Arabic never reached much beyond the kindergarten stage. Consequently I suggested to Meyerhof that he, with his vastly superior equipment, should undertake the work. He acknowledged the need of a translation but firmly and decidedly declined the task. He passed the arduous undertaking to me with the promise that he would give me every assistance in his power if I would assume the responsibility—all equipped as I was. While I was considering the matter, two influences turned the scale, a certain teaching body offered to finance the project, and I quite unexpectedly became the possessor, through the friendly aid of Professor Rustum of Beirut, of the only manuscript copy of the Tadhkirat that had been on the market for many years. And so the die was cast, I decided to proceed with 'Ali ibn-'Isa.

It may be added here and parenthetically that the great Biblioteca Vaticana possesses, among its many other treasures, over 60,000 more or less complete codices, as well as hundreds of early fragmentary writings in every literary language. These books and manuscript folios are now being indexed and annotated, a large number for the first time, with the aid of yearly grants from Carnegie funds, by a corps of scholars and informed cataloguers. Under these conditions one may expect to run across now and then a unique or hitherto unknown item of unusual value.

Professor della Vida kindly kept my request in mind and in March 1934 discovered, greatly to his and my joy and satisfaction, an unedited codex on eye diseases whose title page and colophon he translated and submitted to me. I recognized at once the importance of the discovery which I suspected to be an ophthalmic treatise by that famous thirteenth (1210-1288

A D) century Arabic author and compiler Ibn an-Nafis. The codex in question had long been placed on the list of lost manuscripts. Although quoted by several medieval writers and on the desiderata of Hirschberg, it had never been seen by any of them. It fortunately happened that Dr Meyerhof was at the time engaged in translating one of Ibn an-Nafis's numerous works and is, in fact, the greatest living authority on the literary productions of that author. Accordingly I had a photograph made of the Ibn an-Nafis item and mailed to him for further information and report. I had no hesitation in making this request, since Meyerhof and I had both been pupils of that advanced oriental scholar and master of ophthalmic history Julius Hirschberg and had retained with each other the pleasant personal contact made in Berlin forty years before.

My chief purpose in asking Meyerhof to give me his opinion of the status of della Vida's discovery was to determine what effect the contents of the find might have on my proposed translation of 'Alī ibn-ʿIsā's monograph. Perhaps it might prove to be a better exposition of medieval ophthalmology and put out of court a translation on which I had already expended considerable time and energy.

Following is the report on our treasure trove by Dr Meyerhof.

"I was very happy in the receipt of your precious parcel. I passed the whole evening and most of the night in examining it and now send you my preliminary report.

"There is no doubt that it is the lost work of my friend Ibn an-Nafis! It bears his style as well as the marks both of his thoroughness and of his prolixity. It is as I expected a vast compilation, unhappily without quotation references but the completest work on ophthalmology ever written by an Arab scholar.

I experience some difficulty in translating the Arabic title, which I transliterate as follows: *Kitab al-Muhaddhab fi Tibb al-'Ain*. I suggest tentatively, as an English title, *The Correct Book on Ophthalmology*.¹ While the early ophthalmic treatise of al-Ghafiqi (which I have partly translated and published in French) is more bulky from padding his treatise with an account of every possible subject relating to the eye, Ibn an-Nafis confined himself strictly to such subjects as one finds in a comprehensive but more rational monograph on ophthalmology.

"The MS is complete: the first original leaf and a few subsequent folios have been replaced by carefully written copies in a more modern hand, but the bulk of the codex is in the calligraphy of the copy and corresponds to 851 A. H. (1447 A. D.), about 160 years after the death of the author. The name of the copyist, himself an oculist, has unfortunately been erased (perhaps intentionally), but the MS forms, on the whole, an excellent, legible codex.

"The place of the usual introduction is taken by a three-part preface (I hope later to find time to translate this more carefully for publication) which contains several discussions lacking in other works of the kind and time, e. g., a description of the eyes of animals (mostly after Aristotle) and a more extensive account of the variations in size and color of human eyes than is found in any other eye-books of the day.

"Then follows the body of the work, the main part divided in two sections, one theoretical, one practical. Both of these are quite extensive, part I having 81 folios, part II 107 folios, together with a compilation of all the then known opinions of Greek and Arabic writers on ophthalmology.

"The chapter on the four types of cataract operations is well written but it lacks the touch of personal experience—a defect in most Arabic treatises.

"Finally, there is a long chapter on ophthalmic pharmacology. The importance of this compilation of Ibn an-Nafis is so great that I shall suggest to our medical faculty that 1000 copies of the codex be printed in Cairo at the expense of the university.

"Perhaps in the course of the next two or three years I may find time for a translation into one of the European languages—but that is another story."

¹ Literally: correct after emendations (Professor della Vida)

Medicolegal

Dental Practice Acts Rule Prohibiting Advertising by Dentists Declared Unauthorized—Brown and others, on behalf of themselves and all other licensed dentists in the state of New York similarly situated, sought to restrain the enforcement of rule 8 of the Rules of the Board of Regents respecting advertising by dentists. Rule 8 declared the following form of advertising to be unprofessional and objectionable, and hence a cause for the revocation of a license to practice dentistry:

The employment of letters handbills posters, circulars cards stereopticon slides motion pictures radio newspapers or other advertising devices for the purpose of soliciting patronage, except that a dentist may use personal professional cards of a modest type announcing his name, title address telephone number and office hours.

The supreme court of New York, special term, Albany County, denied the injunction and the plaintiffs appealed to the supreme court of New York appellate division, third department.

The Board of Regents has supervisory powers over the practice of dentistry, and conformably to law, may prescribe canons of conduct. The legislature, by chapter 609, sec. 7, Laws of 1933 authorized the revocation of a dentist's license if he, among other things is "guilty of untrue, fraudulent, misleading or deceptive advertising." The legislature thus set a standard for dental advertising. The rule adopted by the Board of Regents however, is more restrictive than the statute. The Board of Regents may not make laws and, since the statute permits advertising by dentists which is not "untrue, fraudulent, misleading or deceptive" any rule adopted by the Board of Regents prohibiting advertising that does not come within the ban established by the legislature constitutes the exercise of a law-making power not possessed by the Board of Regents and a power that may not be delegated by the legislature. The supreme court, appellate division, therefore, directed a judgment restraining the defendants from enforcing rule 8—*Brown v University of State of New York (N Y)*, 273 N Y S 809.

Optometry Practice Acts Sale of Spectacles by Laymen.—The S. S. Kresge Company operated a store in Jersey City, N. J. Among the goods displayed for sale were spectacles, designed to serve as an aid to human vision. An employee, not licensed to practice optometry in New Jersey, sold to a customer a pair of these glasses. It was stipulated that the employee gave no advice, aid or assistance to the customer in the selection of the spectacles. The employee merely sold the spectacles selected by the customer. The New Jersey state board of optometrists instituted this proceeding against the S. S. Kresge Company, charging it with employing and aiding an unauthorized person to practice optometry. The trial court gave judgment for the board, and the company carried the case to the supreme court of New Jersey.

The company contended, among other things, that if the optometry act is construed to bar the right to sell spectacles under the circumstances involved in this case, it would be an unreasonable exercise of the police power. The supreme court was unable to subscribe to this view. The right to practice medicine and kindred professions for the treatment of human ailments is subject to the paramount power of the state to impose such regulations, within constitutional limits, as may be required to protect the people against ignorance and incapacity, as well as against deception and fraud. The state, in the exercise of the police power, may undoubtedly regulate the practice of such professions for the protection of the lives and health of the people. It may prescribe that only persons possessing the requisite qualifications of learning and skill shall practice these professions. A statute prohibiting the sale at retail of "any spectacles, eyeglasses or lenses for the correction of vision, unless a duly licensed physician or duly qualified optometrist be in charge of and personal attendance at the booth, counter or place, where such articles are sold in such store or established place of business," is a valid exercise of police power. *Roschen v Ward* 279 U S 337, 49 Sup Ct 336.

But, in the opinion of the court, the sale of the spectacles in the present case does not come within the condemnation of

the New Jersey optometry act. That act declares it to be unlawful if any person, company or association employs or aids or assists any unauthorized person to practice optometry, as defined in the act. The act defines optometry, in part, as follows

The practice of optometry is defined to be the employment of objective and/or subjective means for the examination of the human eye for the purpose of ascertaining any departure from the normal measuring its powers of vision and adapting lenses and/or prisms for the aid thereof

Oculists and ophthalmologists pursue a calling quite distinct from that of optometrists. The first has relation to the practice of medicine and surgery in the treatment of diseases of the eye, and the second to the measurement of the powers of vision, and the adaptation of lenses for the aid thereof. It is the primary function of the optometrist to employ means to determine the need of lenses for the correction of defects of eyesight, and for the increase of the power and range of vision. The practice of optometry, therefore, does not include the mere sale, without more, of spectacles, glasses or lenses designed to aid human vision. The statutory definition connotes the employment by the practitioner of means, objective or subjective, for the examination of the eye for the purpose of ascertaining its visual power, and the adaptation of lenses or prisms for the correction of discovered defects or deficiencies. The statute was not intended to apply to the sale of spectacles eyeglasses or lenses as merchandise, or to the mere sale of such to an individual for the use in the correction of his defects or deficiencies of vision, or for the alleviation of the consequences thereof. The power reasonably to regulate the sale of lenses designed to correct vision indubitably resides in the legislature, but it did not choose to exercise it. The judgment of conviction was therefore reversed and the cause remanded.—*New Jersey, State Board of Optometrists v S S Kresge Co (N J) 174 A 353*

Malpractice Liability of Railroad Company for Negligence of Its District Surgeon—The Chicago, Rock Island and Pacific Railway Company contracted with Dr Runyan, and other physicians associated with him in the operation of St. Luke's Hospital Clinic, to act as "District and Hospital Surgeons" for the railway company in Little Rock Ark., and vicinity. The railroad agreed to pay the physicians a definite sum monthly and the physicians agreed, among other things, to render necessary surgical and medical attention to passengers injured on the company's trains, to company employees injured in the course of their employment, and to company employees who were contributors to the hospital fund, which the company administered for the benefit of employees who became sick or disabled otherwise than in the course of their employment.

While operating on an employee entitled to benefits from the hospital fund, Runyan removed an enlarged and infected gland from the inguinal region. The gland ruptured during the course of removal and some exudate therefrom splashed in the eye of the plaintiff, a nurse assisting Runyan in the operation. The eye became infected and eventually had to be removed. The plaintiff sued the railway company and Runyan alleging that Runyan was in the employ of the railroad company and that through his negligence she had been injured. He had been negligent, she alleged, in failing to warn her of the infectious condition of the gland, and in carelessly cutting into the gland and rupturing it without warning her that he intended to do so. After the suit was started Runyan died. Judgment was rendered against the company and Runyan's estate. The company alone appealed to the Supreme Court of Arkansas.

The jury's verdict, said the Supreme Court, that the operation was negligently performed is conclusive. The operation being negligently performed, the company was liable regardless of whether or not it exercised due care in selecting or retaining the physician. The court held that the contract between the company and Runyan created the relationship of master and servant and the master became liable for the torts committed by the servant in the course of his employment. If a person or corporation, continued the court, makes a contract of employment with another, who accepts the employment and agrees to do the work but is negligent in doing it, the employer is liable.

A strong dissenting opinion, filed by three justices, however, criticized the majority holding. The relation, the dissenting justices stated, of master and servant did not exist between the railroad company and Runyan. In *Arkansas Midland R Co v Pearson*, 98 Ark 399, 135 S W 917, the court held that—

A physician cannot be regarded as an agent or servant in the usual sense of the term since he is not and necessarily cannot be directed in the diagnosing of diseases and injuries and prescribing treatment therefor for his office being to exercise his best skill and judgment in such matters without control from those by whom he is called or his fees are paid.

In *Runyan v Goodrum*, 147 Ark 481, 228 S W 397, it was said

The relation of master and servant cannot exist between physicians and surgeons who are not x-ray specialists themselves and the x-ray specialist or roentgenologist whom they employ to assist them in the diagnosis and treatment of diseases.

Also in *Norton v Hefner*, 132 Ark. 18, 198 S W 97, the court said

The doctrine of respondeat superior applies only in case of the negligence of a servant who acts under the direction and control of the master and does not apply to a physician or other professional man who when employed acts upon his own initiative and without direction from others.

In the opinion of the dissenting justices, the railroad company was not liable for Runyan's negligence unless it failed to exercise ordinary care in selecting or retaining him.

However, the judgment against the railroad company was affirmed.—*Chicago R I and P Ry Co v Britt (Ark) 74 S W (2d) 398*

Current Medical Literature

AMERICAN

The Association library lends periodicals to fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent loan only from them.

Titles marked with an asterisk (*) are abstracted below.

Ectodermal Tumors of Skin. C. F. Geschickter and H. P. Koehler, Baltimore.—p. 804

Adamantinomas of Hypophyseal Stalk and Sphenoid Bone.—Zeitlin reports three cases of adamantinoma. The structures present in the first case were suggestive of enamel formation, consisting of epithelial cell layers which were arranged similarly to the pattern found in the enamel organ. The outer layer was composed of columnar cells having a characteristic palisade formation corresponding to the ameloblasts or gonoblast cells of the enamel organ. Immediately beneath the gonoblasts were several rows of flattened cells the axes of which lay at right angles. The innermost layer of cells consisted of star shaped or stellate cells with protoplasmic bridges forming a reticulum. Epithelial pearl formations were present throughout. Toothbud-like projections were seen sprouting from the epithelial cells. Although there were some structures that resembled enamel-forming cells they showed considerable deviation from the normal. The elongated rod cells seemed to arise from the masses of epithelial cells and not directly from the ameloblasts. From the gross description of the second case, it is evident that the tumor arose from within the body of the sphenoid bone filled the sphenoid sinus extended into the posterior part of the roof of the left orbit, left middle ear and right internal jugular vein and invaded the posterior lobe of the hypophysis eroding through the dura and giving local metastasis to the infundibulum. This case therefore gives distinct evidences of a malignant character. In these malignant types of adamantinoma the erosions of the sphenoid bone and the infiltration of the dura and the base of the brain are usually conspicuous features. The third case may be considered an intracystic papillary adamantinoma. The character of this tumor was determined by the interlacing epithelial columns lined by a single row of cuboidal cells, the central masses composed of stellate cells with a tendency to form whorls, and the calcareous deposits and numerous cyst formations. Keratohyaline granules were not demonstrable in any of the tumors. The significance of these granules in differentiating the tumors under discussion from epitheliomas of the skin as emphasized by Erdheim and Jackson can no longer be maintained. Hair follicles, sebaceous glands and sweat glands described by Bostroem, Globus, Shapiro and others in epidermoid cysts simulating hypophyseal duct tumors were likewise absent in these cases. Depending on the stage of formation and differentiation of the oral epithelium the epithelial cells vary in the

formation of the enamel organ. Hypophyseal duct adamantinomas are more common in children and adolescents. The author's first patient was 3 years of age. The clinical picture varies with the location of the tumor and with the age of the patient. The symptoms are largely those of intracranial hypertension disturbance of hypophyseal function and compression of the neighboring structures. Compression of the optic chiasm is the cause of optic atrophy defect in the visual fields and visual disturbances. In the 3 year old child there were no marked evidences of pituitary disturbance or pressure on the hypothalamic region except possibly her precocious intelligence. In the second case the scantiness of the pubic hair and the atrophy of the testicles may be significant. The preoperative diagnosis of the tumors of the hypophyseal duct rests largely on the suprasellar calcification which is often detectable on roentgen examination. It is present in the majority of the cases and when typically developed is of great diagnostic significance, in fact it may be considered pathognomonic.

Metastasis in Bronchogenic Carcinoma.—Samson studied 100 cases of bronchogenic carcinoma in which there were complete necropsies with adequate microscopic control. These were classified as to cell type and 51 per cent were found to be adenocarcinoma, 30 per cent squamous-cell and 19 per cent undifferentiated-cell carcinoma. A comparison of the reported metastases was made in the three groups by the method of coefficients of association, and it was found that each group presented certain general characteristics. The adenocarcinomas showed a strong tendency to involve the central nervous system, adrenals, kidneys, both lungs and to some extent the liver. This is best explained on the basis of predominant hematogenous metastasis with involvement also of the thoracic and abdominal lymph nodes. The squamous cell series showed a marked tendency to local extension rather than widespread metastasis involving the pericardium and bronchial lymph nodes to some extent. In 24 per cent of the squamous cell carcinomas no lung metastases were found. Because of the tendency to local extension this group would appear to offer the best prognosis for radical removal. Judged from the type of organic involvement, the small-cell carcinomas showed little tendency to hematogenous metastasis. The neoplasms in this group showed extensive lymphogenous metastases however associated with involvement of the pancreas, liver and spleen. Because of differences in the type and extent of growth and of metastases, knowledge of the cell type and of the degree of differentiation can be of aid to the clinician in determining the most advisable course of treatment. Such knowledge should obviously be used in conjunction with the physical examination, history and roentgen study.

Chemotherapy of Cancer.—Bergen and his associates used colloidal lead phosphate in treating eighty-one cases of inoperable cancer of various organs. To receive benefit from lead it seemed necessary for patients to pass through a stage of lead intoxication, therefore at least 400 mg. of lead in a course was given if the patient's general condition permitted it. In some the immediate reaction was so severe that relatively small amounts could be given. The eighty-one patients received a total of 476 intravenous injections of lead, the average total dose administered being 440 mg. Sixty patients are known to be dead, fourteen are known to be living and have been carefully examined at the clinic and found to be free from carcinoma two or more years after treatment. Of these fourteen, seven had treatment by roentgen rays or radium, or both, in addition to the lead, seven received only lead. The other seven patients have not been examined at the clinic recently, they are known to have had recurrent or metastatic lesions or satisfactory reports could not be obtained by virtue of their inability to return for examination. The observations suggest that providing a suitable vehicle to transfer lead into cancerous tissue by the systemic route and disturbing bodily metabolism by the introduction of a substance that will hinder the growth of cancer are two important approaches to the treatment of cancer. The present methods of administering lead and other allied substances may afford a possibility for future research. For the present, lead seems to have a field of usefulness in conjunction with surgery. When size, extent and the site of a malignant growth make complete removal impossible, the intravenous

injection of lead seems to do something to bodily metabolism that tends toward suppression of the remaining cancer cells. Possibly the same thing would be true if cancers were treated with lead very early. The opportunity for a trial of this has not been afforded. Systemic treatment with lead affords just one additional hope, but, the authors believe, a more important one than has heretofore been thought for the control of cancer.

Hemorrhagic Encephalitis (Neoparsphenamine) in Obstetric Patients—Plass and Woods discuss the cases of three women one 19 and two 22 years of age, who died during late pregnancy or shortly after delivery in the course of antisyphilitic therapy directed at latent syphilis detected by routine blood Wassermann tests. In two instances hemorrhagic

encephalitis was demonstrated post mortem, while in the third the clinical picture made the diagnosis reasonably certain. Neoparsphenamine was employed in each case six injections totaling 2.2 Gm in the first case and three injections totaling 1 Gm in each of the other two. In addition, four injections of gray oil (2 minims each) were given to the first patient and one similar dose to the third patient. In each instance the initial dose was within the limit usually recommended and succeeding doses were not large, being smaller than the maximal recommended dose (0.45 Gm). Injections were made twice a week, instead of once as is commonly advised. In two instances the spinal fluid Wassermann reaction was positive despite the absence of clinical evidence of cerebrospinal syphilis. In each instance, cerebral symptoms of arsenical poisoning developed within seventy-two hours after the final injection of neoparsphenamine, and death occurred within three days of the initial manifestations, or on the third to the fifth day after the last injection. Two patients developed convulsive seizures, which naturally suggested puerperal eclampsia, a condition which must obviously be considered whenever convulsions appear in the latter trimester of pregnancy or shortly after delivery. In the second case the bizarre character of the convulsions and in the third case the anatomic observations clearly removed this possibility. From a review of the literature, it seems that pregnant women are more susceptible to the deleterious, as well as to the beneficial, effects of antisyphilitic treatment by the modern arsenicals than are other individuals. The clinical picture, as they observed it, was varied and may be confusing, but positive diagnosis can be made by pathologic changes in the central nervous system, more especially by the presence of scattered punctate hemorrhages round the smaller vessels, and usually by an associated edema. Intelligent prophylaxis demands that great care be exercised in giving a first course of antisyphilitic arsenical therapy to a woman with latent syphilis in the latter months of pregnancy.

Management of Prolapse of Uterus—Gordon points out that it has been clearly shown by many operators that even the worst types of prolapse of the uterus may be cured by vaginal plastic surgery. No abdominal operation then should be done for prolapse. Since the parametrium may be united in the midline without removal of the uterus, why remove it? Hysterectomy should be reserved for those patients in whom the uterus is diseased, removal of the normal uterus for the cure of prolapse is unnecessary, and in young women wrong. The Manchester-Fothergill is all that could be desired, and it should have no mortality. That it does not interfere with parturition may not perhaps be proved, but many women have been successfully and easily delivered after operation. Reviewing his results of seventeen years with this operation, he is satisfied that it accomplishes the most with the least risk.

Treatment of Gonorrheal Vaginitis with Estrogenic Preparations—Miller has treated sixty-eight cases of gonorrheal vaginitis with estrogenic preparations. With the exception of the first few cases the preparations used have been purchased in the open market. The amount of vulvovaginal irritation, discharge and the intensity of the reaction was estimated as described by Lewis. Many complicating diseases occurred during the treatment of the children. Fresh infections required much longer treatment than did old infections, emphasizing the part that immunity may play. Relapses are frequently due to reinfection from the urethra and will be found more frequently if long-continued follow-up studies are made. The vaginal infection, whether it is due to a gonococcus or other organism, responds equally well to theelin treatment. The author suggests tentatively that the child be cleared as rapidly as possible with daily injections of at least 100 rat units, preferably in divided doses, diminishing the amount as a reaction is obtained, but maintaining a vigorous squamous cell reaction until the gonococcus disappears, and thereafter maintaining over a period of two or three months a moderately well developed reaction. He cannot say that this treatment is harmless, for he does not know what it is doing to the ovaries. So far at least, deleterious effects have not been manifest. The end results for the forty-two cases of gonorrheal vaginitis that have been observed for six months or longer are given

in terms of negative smears for the time stated, the result apparently had some relationship to the treatment good results, nineteen, temporary control only (up to the present time), sixteen, and frank failures, due either to insufficiency of dosage or to lack of cooperation, seven

Sterilization by Intra-Uterine Coagulation of Tubal Orifices—De Vilbiss began a series of thirty coagulation cases for sterilization in January 1933. In January 1934, twenty patients were reported with tubes blocked, six tubes patent, three with no Rubin test and one not treated. In January 1935, seventeen cases were reported blocked, nine patent, three not tested and one no treatment. Seven patients had become pregnant, three of whom had been reported blocked, one partially blocked and three not tested. Twenty-two are reported non-pregnant, some of whom are using contraceptives. The author concludes that intra-uterine coagulation of the tubal orifices is contraindicated in untreated syphilis because of the liability to hemorrhage. It must also be used cautiously in cases of gonorrhea, since the blocking of tubes may interfere with tubal drainage, although this infection in itself will probably render the woman sterile. The resulting irritation from the coagulation current may also light up an old infection temporarily. Two such cases occurred in the series. The patients suffered pain and elevation of temperature for several days, though without any serious after-effects. There is no positive assurance that the blocking of tubes with the coagulation method will be permanent. The intra-uterine cautery or coagulation method of sterilization may be recommended when surgical intervention is inadvisable or contraindicated.

Hemorrhagic Encephalitis—Baker reports twenty cases of a peculiar involvement of the central nervous system (hemorrhagic encephalitis), since clinically the patients present a typical picture of encephalitis and pathologically the most striking lesion is a hemorrhagic involvement of the brain. Hemorrhagic encephalitis may be characterized clinically as an acute ailment of the central nervous system occurring in previously healthy young persons and manifesting itself by a sudden onset, headache, an abrupt rise of temperature and a

rapid loss of consciousness. Convulsions are common; the extremities are spastic and the reflexes are frequently abnormal and variable. Death ensues in from a few hours to several days after the onset of the illness. The most conspicuous feature of this disease is the pathologic picture in the brain. It is chiefly hemorrhagic and predominantly in the white matter. The hemorrhages vary widely in number and size, from extensive extravasations that destroy much brain tissue to tiny perivascular bleedings. In the brains of patients who survive the first few days there are often observed areas of nonhemorrhagic perivascular demyelination, which are invaded by scavenger cells. Consistent specific changes in the ganglionic cells have not been observed. An occasional blood vessel shows a slight perivascular infiltration of mononuclears. A few widely scattered polymorphonuclears can be detected in the areas of degeneration. Postmortem study shows that all the organs except the brain are normal. Cerebral hemorrhages may frequently be found in other diseases but by careful clinical and pathologic study these can easily be differentiated from true hemorrhagic encephalitis. The brain tissue from one case of hemorrhagic encephalitis has proved virulent to rabbits on intracerebral inoculation. The author accepts hemorrhagic encephalitis as a clinical entity and believes that it is entitled to a definite position in neurologic nosology.

Lesions of Coronary Arteries in Rheumatic Fever

Gross and his associates discuss the incidence of various progressive, retrogressive and inflammatory processes in the coronary tree as a whole in rheumatic fever. Their studies are confined to the incidence of these phenomena in active rheumatic cases and in normal controls. They describe distinctive vascular lesions found in active as well as inactive cases of rheumatic fever. Their study is based on an examination of 100 hearts, sixty-six of which were from cases of acute rheumatic fever with Aschoff bodies in the myocardium and presenting the evidences of activity. The remaining thirty-four hearts were from inactive cases presenting the typical anatomic evidences of inactive rheumatic fever. Fifty normal hearts, representing age periods from birth to the ninth decade, served as a base line to establish deviations from the normal. The lesions of the coronary artery tree found in active and inactive rheumatic fever are divided into (1) evolutionary changes also found in normal control cases and (2) lesions occurring either uncommonly or never in normal control cases. Many of the vascular diseases falling into the second category are so peculiar and encountered so rarely in other diseases that their presence should lead to a strong suspicion of rheumatic fever in its active stages. The coronary arteries and their branches in the heart show marked damage due to rheumatic fever. This damage is vivid and impressive in the active cases. In the inactive cases the lesions do not appear to be essentially dissimilar from the normally occurring evolutionary age period changes. The observations in the main coronary arteries in the inactive cases are by no means as strikingly clear cut as are those in the active cases. Here, besides the earlier development of intimal hyperplasia (often of a fibrotic type) and medial elastification and scarring, there also occurred in a significant incidence (15 per cent) a variety of arteritides, which are represented by various grades of exudative and necrotizing inflammation and by thrombosis as well as by certain peculiar vascular and intravascular lesions, viz., edema palisade formation, endarteritis verrucosa and granular thrombotic lesions. Together with these lesions in the main coronary trunks, the smaller vessels distributed throughout the myocardium presented similar changes in nineteen cases. The total incidence of the various types of arteritis occurring in either the main coronary trunks, the smaller myocardial vessels or both, was 33 per cent. There occur in the smaller branches of the coronary arteries many different types of vascular lesions. The variety and wide distribution of these lesions afford additional support to the belief that the heart is the most extensively involved organ in the body in this disease and that the various rheumatic vascular disorders of the heart produce their damage during the active as well as the inactive stages.

Diffuse Arteritis of Syphilitic Origin—Derick and Hass describe a case of widespread progressive chronic arteritis in a young adult with syphilis. The small arteries were involved

almost exclusively, and all three coats of the vessels were included frequently in the lesion. In most instances the vessels were occluded partially or completely, either by the marked thickening of their walls, by the formation of thrombi or by a combination of the two processes. Infarcts of various organs often were present in regions where the most severe vascular lesions were found. The etiology of the arteritis has not been proved conclusively, but the authors believe that it is the virus of syphilis.

Physical Factors in Intracavity Radium Therapy — Weatherwax states that the radiologist should plan intracavity treatment of a lesion, keeping in mind (1) the location of the lesion, (2) the distance of the applicator from the surface of the lesion, (3) the filter employed, (4) the size and shape of the applicator and (5) the penetration. Experience has demonstrated that in the treatment of many intracavity lesions it is impossible to deliver a lethal dose throughout the entire lesion with radium alone. The lethal zone produced by radium can be extended by combining roentgen irradiation, and it would seem advisable to have the height of tissue reaction for both radium and roentgen irradiation occur at approximately the same time. Assuming that radiologists have experience in the proper evaluation of the factors pertaining to intracavity irradiation, the greatest advances in the future will be made by obtaining both clinical and experimental evidence in coordinating intracavity and roentgen or teleradium irradiation.

Primary Hemangioma of Third Lumbar Vertebra — Livingston discusses a primary hemangioma of the third lumbar vertebra in a man 44 years of age. The patient was admitted to the hospital for treatment of osteo-arthritis, complaining of low back pain. When a child the third lumbar vertebra was injured, which necessitated the wearing of a plaster cast for six months, following which there were no symptoms for many years. He played football while in college. In 1921 pain suddenly developed in various joints at intervals. His condition was diagnosed as rheumatoid arthritis, including the spine. In 1932 an acute cystitis appeared suddenly followed by chronic prostatitis. The condition cleared in about two months. Signs and symptoms when present are indistinguishable from those produced by spinal cord tumor, i. e., compression myelitis. On deep palpation and fist percussion there is some tenderness along the lumbar spine, especially the third and the sacro-iliac joints. About 50 per cent of the limitation of motion in abduction and flexion in the right hip is due to arthritis. Roentgen examina-

tion of the lumbar spine shows evidence of a hemangioma of the third vertebral body. This is characterized by a decrease of the total density of the vertebral body and the formation of vertical striations. There was considerable reaction to the first roentgen dose but only a little to the second.

Roentgen Dermatitis Treated with Aloe Vera.—The Collinses report a case of severe roentgen dermatitis treated with fresh whole leaf of aloe vera in a case that had become progressively worse until there was extensive desquamation with oozing of serous fluid. A skin graft was indicated. At the time of examination the patient was furnished with a quantity of aloe vera (fresh whole leaf) for local application, with the hope that this material might serve as a palliative. Twenty-four hours later she reported that the sensation of itching and burning had entirely subsided. She was instructed to continue its use, and when she was seen from time to time during the next five weeks the condition was found to be progressively improved, and after one month there was complete regeneration of the skin of the forehead and scalp, new hair growth, complete restoration of sensation and an absence of scar. There was at this time a slight blanching of the affected area. When last seen the healed area appeared to be completely cured, with no indication whatever of a relapse. The aloe vera leaf contains a large quantity of a light yellowish green material, which is used for local application. The leaf may be split lengthwise or cut into thick cross-sections and the intestine material macerated. While this is still fresh, liberal quantities are applied to the area to be treated and this is covered with a neutral, nonporous substance (such as waxed paper). A bandage or adhesive plaster may then be used to secure the mass in place. An hour or two is the life of an application, it will then be found to be dark and gummy. It is simply washed off carefully with warm water, without soap or medication. The applications may be renewed as often as may be desirable.

Salzmänn's Nodular Corneal Dystrophy —Brown and Katz describe the pathologic process of Salzmänn's nodular corneal dystrophy as a noninflammatory, slowly progressive process, early hypertrophic and later degenerative, producing marked and varied alterations of the epithelial layer, Bowman's

membrane and the outer third to half of the corneal stroma. All descriptions of the histopathologic changes present will necessarily be a description of a stage of the disease. It is doubtful whether any two specimens of this condition from two different nodules will ever be secured that will be identical in their histopathologic changes. Salzmann's nodular corneal dystrophy should be treated surgically. The indications are a reduction or threatened reduction of visual acuity. Complete removal of the nodule or nodules holds out the only hope for successful treatment. The nodule or nodules may be removed completely without perforation of the cornea with a small Graefe knife, sharpened to about half its original size. All of the nodule above the surface of the cornea as well as part of the portion that extends into the corneal stroma can be removed readily and safely. To remove the base completely, a trephine is used to cut through the various layers of the pathologically involved corneal stroma. These can then be removed with the Bowman knife and an Elliot scleral disk forceps. The thickness of the removed tissue will depend on the depth at which the cornea is no longer opaque. The trephining is repeated in whatever direction is necessary until the floor of the dystrophic nodule becomes completely transparent.

Basophilic Invasion of Neurohypophysis and Hypertensive Disorders.—Spark compared histologically the pituitary glands from seventy persons with essential hypertension, eleven persons with evidence of antecedent hypertension and 108 with various nonhypertensive diseases. He observed that those from persons with essential hypertension showed no greater degree of basophilic invasion of the pars nervosa than those from nonhypertensive ones when groups of approximately the same ages were compared. The invasion of the posterior lobe by basophils is in some way related to the aging of the organism and possibly to some sex factor as well. The immediate stimulating factors are unknown. There is no morphologic evidence to support the hypothesis that essential hypertension and eclampsia of pregnancy are due to a hyperactivation of the neurohypophysis by basophilic cells.

Study of Mitochondria in Squamous Cell Carcinoma.—Cooper and Seelig point out that no significant differences are apparent in the mitochondria-cytoplasmic ratios of the normal and of the cancerous tissue. Thus, although the phospholipid content of malignant tissue is greater than that of normal tissue, according to Bloor and Bierich, Detzel and Lang, this difference cannot be demonstrated morphologically by any quantitative change in the mitochondria of cancer cells. In fact, the mean mitochondria-cytoplasmic ratio, i. e., the mitochondrial surface per hundred cubic microns of cytoplasm, is somewhat greater for the normal tissue (65) than for the cancer tissue (475). The mean mitochondria-cytoplasmic ratios for the three grades of squamous cell carcinoma studied are not significantly different. Less difference was found in the mean mitochondria-cytoplasmic ratios for each of the three grades of squamous cell carcinoma than was observed between the ratios for normal and for carcinomatous tissue. In some carcinomas of grade 1 or 2 in which keratinization was marked, almost complete disappearance of the mitochondria was noted. In other grade 1 carcinomas however the mitochondria were more numerous than in tumors of grade 3. Consequently, a quantitative estimation of the mitochondria in squamous cell carcinoma does not form any basis for grading.

Effects of Sclerosing Solutions on Subcutaneous Tissues.—Mahorner and Ochsner injected 2 cc of the following sclerosing solutions subcutaneously at different points into dogs: 5 per cent sodium morrhuate, 5 and 3 per cent sodium gynecardate, 5 per cent sodium hydnocarpate, quinine and ethyl carbamate, 40 per cent sodium salicylate, 75 per cent invert sugar and equal parts of 50 per cent dextrose and 30 per cent sodium chloride. The areas into which the injections were made were removed after one hour, twelve hours, twenty-four hours, four days and ten days. They found that the solutions produced necrosis of the subcutaneous tissue with a zone of inflammatory reaction surrounding it, liquefaction necrosis and subsequently fibrosis—in other words, a sterile abscess, which resulted in ulceration only twice. Since destruction of endothelium is essential in the intravenous injection of sclerosing solutions for the treatment of varicose veins, the property of injuring cells locally is desirable provided the systemic effect is not untoward. A 5 and 3 per cent solution of sodium gynecardate, one of 5 per cent sodium morrhuate and one of 40 per cent sodium salicylate seemed to produce more complete necrosis of tissues than did the other solutions tested. This is in similar ratio to their thrombus-producing effectiveness as tested by intravenous injection. A 40 per cent solution of sodium salicylate is not advocated for clinical use.

Carcinoma of Pancreas.—Ransom compiles the records of sixteen cases of carcinoma of the body or tail of the pancreas observed during a period of eight and a half years. In every case the diagnosis was verified by operation or necropsy. Microscopic confirmation of the diagnosis was obtained whenever biopsy specimens could be taken. During this period fifty-eight cases of carcinoma of the head of the pancreas were seen. The youngest patient was 40 years old and the oldest patient was 69 years. The average age was 57 years. Operation was performed on all the patients except the two who died, in whom the diagnosis was confirmed by necropsy. There were no deaths at operation. Of the fourteen patients operated on, six were discharged from the hospital unimproved, seven completely or partially relieved from pain and one definitely worse. In the group of patients who were relieved from pain there seemed to be no relation to the type of operation, and the improvement following simple exploratory laparotomy in some cases was as great as that following some of the more complicated procedures. Of the eight cases in which operation was performed and in which the time of death was ascertained, the average duration

of life following operation was four and five-tenths months. The average duration of symptoms prior to admission was five and seven-tenths months. In the patients who died without operation the duration of symptoms was eight months and one month, respectively.

Prognosis in Cancer of the Breast—Stanton states that the prognosis in cancer of the breast is by no means hopeless. In favorable cases, postoperative survival without demonstrable recurrence for more than twenty years is by no means uncommon. The woman who is fortunate enough to have a thorough operation performed for a slowly metastasizing tumor before glandular involvement has taken place stands an excellent chance of never having a recurrence or of living for many years without a demonstrable recurrence. Surgery has little to offer the woman with a rapidly metastasizing tumor. In the case of the slow-growing, less malignant tumor, even though operation is performed relatively late, the postoperative survival is liable to be prolonged in keeping with the course of the progress indicated previous to the operation.

Experimental Pulmonary Embolism Associated with Venoclysis—According to Rumold, a foreign body, such as a cannula, lodged in the vein of a dog produces an inflammatory reaction throughout the wall of the vein with partial occlusion of the lumen by an organizing fragile thrombus. All the necessary factors for thrombosis are present. There was no difference in the reactions caused by the various types of commonly used cannulas. The results of the experiments indicate that a foreign body in a vein is more active in the production of thrombi than is the infused solution. The animals used in the experiment lost weight while receiving a 10 per cent solution of dextrose given in the same quantity per body weight as it is given clinically to man. All dogs showed a high incidence of pulmonary infarction and thrombosis after having received venoclysis. The pulmonary infarcts were usually associated with other pulmonary pathologic changes, such as pneumonia and edema. Well formed clots were injected into the external jugular veins of dogs having apparently normal lungs. At necropsy, pulmonary thrombi were found but no pulmonary infarcts. The experiments show that pulmonary complications, such as bronchopneumonia and edema, predispose to pulmonary infarction when thrombi are circulating in the pulmonary vessels. By analogy it seems probable that pulmonary embolism and thrombosis are not infrequently associated with continuous venoclysis as used in man, although they may not always be recognizable clinically. Continuous intravenous infusions are not without danger.

Cerebrospinal Fluid in Tumors of Brain—Hare studied the composition of the cerebrospinal fluid in 218 cases of verified tumor of the brain. The study of the fluid was of

little value in the differential diagnosis of tumors from other diseases of the brain. An increase of protein and of globulin in the fluid obtained by lumbar puncture occurred in 61 per cent of meningiomas, 64.8 per cent of multiform glioblastomas and 100 per cent of acoustic neuromas and other tumors in the lateral recess of the posterior cranial fossa, and in 35.4 per cent of supratentorial astrocytomas, 60 per cent of supratentorial and 20 per cent of subtentorial medulloblastomas, in other pathologic types of intracranial tumor an increase of protein and globulin occurred in some cases but not in others. Increases were not found in the oligodendrogliomas, dermoid cysts or papillomas of the choroid plexus. Changes in the protein and globulin of fluid removed by ventricular puncture are more infrequent, but in supratentorial growths in one cerebral hemisphere the fluid removed from the lateral ventricle of that side will often contain more protein and globulin than that from the other ventricle. In infiltrating growths, increase of protein and globulin in the lumbar fluid is more frequent in the glioblastomas and astrocytomas when the tumor is entirely subcortical. The largest increase of protein and globulin in the lumbar fluid was found in the multiform glioblastomas and in acoustic nerve tumors, and in the ventricular fluid in the multiform glioblastomas. The increase of protein in the lumbar fluid varied between 50 and 490 mg., and of globulin between 1+ and 4+. The lumbar manometric pressure was normal in sixty-nine cases. There was a pleocytosis of more than 10 cells per cubic millimeter in 86 per cent of the lumbar fluids. When a brain tumor is suspected, an increase of protein and globulin in the fluid obtained by lumbar puncture is of some value for the diagnosis of the pathologic nature of the growth. In the more differentiated gliomas, changes in the fluid are more unusual. The examination of the fluid may be of aid in the differentiation between intracerebellar and extracerebellar growths and between supratentorial infiltrating tumors that are entirely subcortical and those that involve the cortex as well.

Susceptibility of Ferrets to Virus of Common Cold—Noble and Branard injected filtrates from forty persons with colds into twelve ferrets. Of these animals eight were used only once and four were used twice, the inoculation with a second virus being given only when the first had failed to infect, and after a rest period of from seven weeks to three months. Four of the twelve ferrets developed symptoms consisting of elevation of temperature, increased nasal secretion, and in one or two instances lacrimation and lethargy. In the temperature curve, an initial elevation appeared in from twenty-four to seventy-two hours and lasted from twenty-four to forty-eight

hours, this was followed by a depression, which lasted from twenty-four to seventy-two hours. The normal temperature seldom exceeded 102.5 F. The maximal elevation following inoculation was 104.1 F. which lasted for two days. Rhinorrhea of mild character appeared in from twenty-four to seventy-two hours and lasted about four days, the secretion was mucoid, never mucopurulent, and was sometimes sufficient to wet the hair about the nostrils. On the third or fourth day the animals were sometimes drowsy and difficult to arouse. An attempt was made to transmit the infection from ferret to ferret and from ferret to human being. The human subject, who had repeatedly handled the ferrets and had been exposed to their respiratory secretions when they sneezed or coughed on being inoculated, had never reacted to them. The second ferret in the series showed no symptoms, but the human subject who was not isolated after inoculation, developed nasal obstruction and slight rhinorrhea in eight hours. These symptoms were mild and lasted about thirty-six hours.

Acetanilid Poisoning—Payne studied the records of several patients poisoned by proprietary preparations containing acetanilid. In most cases poisoning was insidious and followed years of addiction. Abrupt withdrawal of the drug was usually followed by three or four days of restlessness and excitement. Acetanilid appeared to be habit forming. A small amount of acetanilid (0.3 Gm.) would have a completely quieting effect on a patient quite manic following abrupt withdrawal of his pet nostrum, an effect that could not be duplicated with barbital or morphine. Cyanosis was observed in all cases, disappearing or fading rapidly to the more persistent gray discoloration on withdrawal of the drug. Tachycardia was frequent, but there was no evidence of heart disease except in one case, in which symptoms disappeared after gradual withdrawal of the drug. A wide variation in red blood cell counts was noted and an attempt made to correlate cyanosis, dyspnea and weakness with anemia. Although anemia was often associated with weakness many cases showing extreme cyanosis,

dyspnea and weakness presented normal or increased red blood cell counts. Since in every case the toxic symptoms of acetanilid poisoning were partly obscured or further complicated by the bromides contained in the "patent medicine" used, the author experimented with dogs (two), restricting the intoxication to acetanilid alone. The first effect of these experiments after daily acetanilid ingestion was an anemia. Following prolonged administration, the animals gained tolerance. After ingestion of acetanilid there was a transient methemoglobinemia and increase in blood phenol. During methemoglobinemia, oxygen capacity falls and symptoms of anoxemia may result. No cardiac damage was demonstrable by electrocardiograms.

Diseases of Peripheral Arteries—Allen discusses Raynaud's disease, erythromelalgia, thrombo-angitis obliterans and arteriovenous fistula as diseases of the peripheral arteries. The color of the extremities is of little diagnostic value and, when too much stress is placed on this single manifestation, errors in diagnosis result. Thus vasomotor changes simulating Raynaud's disease may be a symptom of thrombo-angitis obliterans and the excessive redness of the extremity in the dependent position in thrombo-angitis obliterans and arteriosclerosis obliterans may be erroneously attributed to erythromelalgia. Mechanical methods are likewise of little value in diagnosis. Such procedures serve their best function in physiologic studies and records of vascular disease, and as such they are worthy of great respect, careful examination of the patient and of his symptoms, however, is adequate for diagnosis in all but a small proportion of cases. Careful examination of patients with suspected disease of the peripheral blood vessels is an absolute necessity. This consists of careful palpation of the dorsalis pedis, posterior tibial, popliteal, femoral, radial and ulnar arteries for pulsations, determination of the effect of posture on the color of the extremities, a search for inflamed or thrombosed superficial veins and for varices, an estimation of the temperature of the parts and a notation of atrophy, minor trophic changes or frank gangrene.

Compression Fractures of Spine—Jostes submits a method for treating compression fractures of the spine in which after the diagnosis has been made the patient is placed on a hospital bed with an automatic knee elevator. The head of the patient is placed at the foot of the bed, bringing the site of the fracture over the knee rest, which is elevated until the spine at the site of the fracture is hyperextended sufficiently to bring about reduction. This can be done in from twelve hours to four days. At intervals lateral views of the spine are taken without disturbing the position of the patient. The film casset is forced firmly over the prominence of the knee elevator, thus depressing the mattress sufficiently to permit a true lateral view of the spine on the plate. If complete "decompression" of the vertebral body has been accomplished, the patient can be left in the position on the bed until the fracture has healed or placed in a hyperextension plaster jacket for a period of twelve weeks. No weight bearing is permitted. A hyperextended celluloid jacket is worn for a period of another three to five months. During the latter period the patient is up and about.

Glaucoma—Schroeder explains all the different stages of glaucoma on the basis of nutritional edema, except that in inflammatory glaucoma an infection is superimposed. The active stage of acute glaucoma he considers an angioneurotic

edema of the eye. Schamberg recommends calcium lactate and desiccated adrenal in the treatment of angioneurotic edema, Lagrange and Gouterman use similar treatment in glaucoma. In the etiology of glaucoma as a nutritional edema he considers protein deficiency due to faulty diet, faulty assimilation, the anemias (primary and secondary) due to infection, nutritional disturbances or hemorrhage (frank and occult) and possibly vitamin B deficiency as an accessory factor.

Combined Artificial Pneumothorax and Phrenicectomy for Closure of Diffusely Adherent Tuberculous Cavities.—Gillick states that cavities of the upper lobe diffusely adherent to the chest wall are noncompressible under pneumothorax treatment alone. Cavities attached to the parietal pleura by fixed string and band adhesions can be compressed by pneumothorax combined with phrenicectomy. The explanation of the combined treatment is based on the fact that retraction of the compressed upper lobe toward a fixed point is influenced by the tendency and tension of the lobe toward the root and the contraction capacity of the stretched adhesion. While the diaphragm remains active, tension toward the root dominates and the upper lobe, suspended before two fixed points, continues to retract toward the hilus. The cavity is pulled from the attachment to the adhesion, and the enlargement of the cavity and tearing of the treated lung may take place. Phrenicectomy is indicated as soon as such enlargement becomes appreciable. Following the paralysis of the diaphragm, the tendency of the lung to retract toward the root or the hilus gradually diminishes. The contraction capacity of the stretched adhesions commences to prevail and the upper lobe begins to retract toward its attachment to the adhesion. The raising of the paralyzed diaphragm seems to play no part in the obliteration of the cavity because cavities seem to close in the same manner, whether the diaphragm is raised, lowered or remains unchanged. This has been noted particularly in cavitations of the left side, which seem to close equally well, although the left diaphragm seldom rises to a high level. It would appear that several months are required for relaxation of the lung and closure of the cavity after a phrenicectomy in contrast to the rapid closure obtained by cauterizing the holding adhesions by means of intrapleural pneumolysis. It is assumed, of course, that the adhesions are accessible for cauterization, although roentgen evidence often fails to provide positive proof. The continuance of the closure of the cavity must be brought about by the maintenance of the proper pressure by refilling.

Hemolytic Icterus with Infantilism.—Langston cites a case of hemolytic ictero anemia associated with skeletal and genital infantilism. As far as can be determined from the history, the onset of the two conditions was simultaneous. Hence a causal relationship of the ictero-anemia to the infantilism is suggested. The hemolytic ictero-anemia was relieved by splenectomy, with characteristic response. Following recovery from the operation, hormone therapy (growth and sex) was instituted. Twenty-seven months later, normal height (for his family) and normal genital development had been attained. The increase in height in this period of time was 6½ inches (16 cm.). Roentgen studies suggest that closure of the epiphyses is progressing slowly, if at all, and further increase in height may be expected. This young man's general health is now excellent, and he is able to carry on the work of a normal person.

Technic of Bronchial Lavage.—Minter used the following procedure for bronchial lavage in a severe case of bronchiectasis. The method differs from that used by Stitt and is safe and simple. The patient is seated in a chair and inclined toward the side desired for lavage. The head is held back and the tongue pulled forward. The tip of a number 12 French catheter is placed on the base of the tongue and held in position by the patient. While the patient breathes normally, the hypertonic solution of sodium chloride of Bledsoe-Fisher is introduced by gravity through a 20 cc Luer syringe. An amount of solution sufficient to fill the dilated bronch and cavities, but less than enough to interfere with respiration, is injected. This amount is determined by trial and varies from as little as 30 cc to as much as 400 cc. After the proper amount

of fluid has been injected, the patient sits quietly to permit the retained pus to float out of the cavities. The pus and the solution are then expelled by postural drainage and the procedure is repeated until the washings are clear. Then 100 cc of a 1:2,000 aqueous solution of sodium ethylmercurithioralicylate (merthiolate) is injected and permitted to remain in the lung for five minutes. It is then drained and 5 cc of endolysin is injected, to remain. The amount of solution used, the number of washings necessary and the frequency of lavage vary with the size of the cavities, the amount of secretion and the condition of the patient.

Gonococcal and Meningococcal Endocarditis.—Ross and Greaves cite three cases of bacterial endocarditis in two of which it was proved that the gonococcus was the causative agent. Swartz's medium, modified by omitting the agar, was used in obtaining the blood cultures. For inoculation, 15 cc of blood was used, care being taken to have the medium at body temperature when the blood was introduced. Twenty-four hours later there was a scanty growth of gram negative diplococci. The growth increased during the next twenty-four hours, after which it rapidly died out. All attempts to obtain subcultures failed. In the third case the meningococcus was not definitely shown to be the cause of this endocarditis, but there is rather strong presumptive evidence that it was. There was a fairly definite history of rheumatic fever in childhood. Meningococcal bacteremia may exist for weeks or months before meningeal signs appear. Before the appearance of the meningeal signs in this patient, he had a daily temperature of 100 F with a cardiac disability that was gradually increasing in severity. As soon as the specific therapy was begun, the temperature became normal and the cardiac condition became stationary and then slowly improved as compensation occurred. It is reasonable to assume that the antimeningococcal serum exerted a specific action on any meningococci localized in the endocardium, halted the progress of the endocardial lesion and permitted recovery within the limits of the damaged heart to compensate.

Methenamine as a Urinary Antiseptic—Heathcote determined the effect of exposure at 37 C for periods of three and six hours of *Staphylococcus aureus*, *Bacillus coli-communis* and *Bacillus coli-alcaligenes* to a 1:500 solution of methenamine at pH 5, 6 and 7. At pH 7 no definite effect on the growth of any of these organisms could be observed, even after six hours. At pH 6 an exposure of three hours produced no effect in the case of *Staphylococcus aureus*, a doubtful effect with *B. coli communis* and a considerable effect in the case of *B. coli-alcaligenes*. An exposure of six hours produced a doubtful effect in the case of *Staphylococcus aureus* but a well marked action on the others. At pH 5 the growth of *Staphylococcus aureus* was definitely reduced by six but only doubtfully by an exposure of three hours. In the case of the other organisms, the acidity of the medium itself was sufficient to obscure the effect of methenamine. Similar experiments with borax, 1:500, at pH 8.5, showed no effect on *Staphylococcus aureus* but a considerable reduction in growth in the other organisms. The two factors of the greatest importance as to whether an antiseptic strength of formaldehyde will be reached in the urine of a patient taking methenamine are time and the reaction of the urine. In infections of the upper part of the urinary tract there will not be sufficient time for such a strength to be developed. In acute cystitis a urine sufficiently acid to produce such a strength of formaldehyde will cause such pain and frequency of micturition as to prevent any effective action. In chronic cystitis there may be hope of reaching an antiseptic strength of formaldehyde over a long enough period to be effective. Methenamine might be a valuable prophylactic in cases in which repeated catheterization will be needed. Borax might be of value in the treatment of acute or chronic cases of cystitis, especially if due to a coliform organism.

Radiology of the Appendix—Wood states that roentgen representation of the appendix may be obtained in all cases in which the lumen of the appendix is not obliterated or obstructed. The method of filling the organ consists in giving a preparation of barium with milk or corn flour at night following this after

an interval of three hours by a dose of magnesium sulphate. Roentgenograms are obtained on the following morning and are continued at such intervals as may appear necessary during the following days until the cecum is entirely empty. Of the 100 patients examined by the author during the last two years, the appendix was successfully filled in ninety-three and failed to fill in seven. Thirty of the patients were operated on, and the roentgen appearances correlated with the operative observations and the pathologic reports. In twenty-eight cases gross and obvious changes in the appendix were noted at operation, while the remaining two showed no evidence of abnormality. The normal appendix gives characteristic appearances in the roentgenogram, and, conversely, the abnormal appendix can also be detected readily, as a rule, from alteration in its contour, emptying rate, position and other changes. A large single fecalith, if it contains calcium, may be visible in a plain roentgenogram and is usually seen close to the right iliac crest. The most characteristic changes are seen when the appendix is the seat of subacute inflammation. There is obvious dilatation of the lumen, especially at the distal extremity, fixation is present in one position and, owing to the diminution or absence of peristalsis, there is delayed emptying of the barium, as the appendix is generally the last to empty. When the appendix lies behind the cecum, it is concealed from view in the earlier roentgenograms. As the cecum begins to empty, however, it comes into view, and it is then sometimes possible to obtain roentgenograms showing its shape and position. When the colon is spastic, the appendix tends to be contracted and the lumen is narrow. When the colon is found to be atonic, the atony appears to affect the appendix at the same time, and it fills with considerable ease and shows a large lumen. Dilatation of the lumen of the appendix appears to be one of the most important roentgenologic signs of disease, especially when it affects the distal extremity and is accompanied by retention of the barium.

Excretion of Estrogenic Substance During Pregnancy—Cohen and his associates present data showing that the first fact of physiologic interest is that during the greater part of

pregnancy more than 99 per cent of the total estrogenic material excreted in the urine is in the "combined" ether-insoluble form, which possesses only a low physiologic potency. It is therefore no longer difficult to reconcile the production of large amounts of estrogenic substance in the body during pregnancy with the fact that its injection into pregnant animals may interfere with the normal course of gestation. Either true or pseudo labor is accompanied and may be preceded by a fall in the "combined" theelin and theelol and a rise in the 'free' forms of each excreted in the urine. The free theelin or theelol is that fraction which can be extracted from the fresh untreated urine with ether. The combined theelin or theelol is that which can be extracted from the urine only with ether after treatment with acid. It is impossible to determine from the available data whether these changes are caused by the events that initiate labor or whether they are themselves factors in the mechanism of parturition. It is clear from the work of Zondek that the animal body is capable of converting large amounts of administered estrogenic substance into a combined form which is physiologically inactive and from which it may be released by acid hydrolysis. The fact that 99 per cent of the hormone excreted during pregnancy is in such a form suggests that the pregnant woman has the power of similarly inactivating much of the estrogenic substance that she produces. The authors reason that a factor in the initiation of labor is the production in the body of larger amounts of free estrogenic substance of a high physiologic potency, either by hydrolysis of the previously formed combined hormone or by some interference with the normal mechanism of inactivation of the hormone after it is produced. The decrease in the amount of total estrogenic substance excreted just prior to and during labor could be explained on the grounds of the utilization of some of that present in the free state at this period, while the increase in the free hormone excreted might be supposed to represent the unutilized excess.

*Obliteration of Right Branch of Portal Vein N. Strajenko—p 469
*Corneal Cholesterol Arc or Circle Madeleine H. Paillard—p 471

Obliteration of Portal Vein—Strajenko describes the case of a man, aged 37, in whom obliteration of the right branch of the portal vein was diagnosed. This was later confirmed at necropsy. As a result he believes that a syndrome exists which permits this condition to be diagnosed during life. It consists first in a splenomegaly accompanied by profuse and repeated gastric hemorrhages, total absence of cirrhotic changes in the right and left lobes of the liver, and absence of ascites. An ascites may nevertheless appear temporarily after hemorrhage and disappear as the blood regenerates. In addition, the syndrome consists of an exceptional development of the subcutaneous collateral anastomoses communicating with the umbilical and para umbilical veins. The author believes that this description should allow any clinician to suspect obliteration of the principal right branch of the portal vein before its entry into the liver.

Corneal Cholesterol Circle—Paillard describes three types of cholesterol deposits in the cornea. The first she calls an arc, the second a circle, and the last, for which she has found no adequate name, is a circle of greater width. Altogether 420 cases were observed by her or by Henri Paillard. Proved biliary lithiasis occurred in 11 per cent, xanthoma in 7 per cent, gouty tophi in 2.5 per cent, dry polyarthritis in 13.5 per cent, orbital cellulitis in 26 per cent and arterial atheroma in 2 per cent. The coincidence is less than with gallstones—a fact which indicates that corneal cholesterol precipitation is an earlier lesion in the family of cholesterol disorders than biliary lithiasis. The condition is nevertheless a sign of some significance.

- *Curable and Incurable Phases of Alimentary Dystrophies G. Mouriquand—p 489
Reflections on One Hundred and Eight Gastrectomies for Ulcer J. Duval—p 491
Experimental Encephalitis of Rabbit A. Phylactos—p 493

Phases of Alimentary Dystrophies—Mouriquand believes that the stages of alimentary dystrophy due to deprivation of vitamin C may be differentiated. The first phase he divides into predeficiency, intermediate and dystrophic phases. In the scorbutic infant in this stage, supplying vitamin C produces increased weight and restoration of nutritive equilibrium. The second stage is that of curability of the deficiency dystrophy but incurability of the general dystrophy. There is finally a stage of complete incurability. At this time, specific treatment comes too late, cachexia is extreme. Necropsy shows hemorrhages in the femoral region.

- *Treatment of Addison's Disease by Common Salt G. Marañón, I. A. Collazo and J. Jimena—p 505
Action of New Pancreatic Hormone in Hypertensives P. Bernal—p 507

Treatment of Addison's Disease by Common Salt—Marañón and his co-workers treated twelve cases of Addison's disease with oral administration of sodium chloride. The basis for this therapy arises from the disturbance in sodium and potassium ratios in adrenalectomized animals and patients with Addison's disease. They feel that the sodium-potassium disequilibrium produced by the adrenal insufficiency might well be the principal cause of the severe dehydration present in Addison's disease. Whatever the mechanism, however, the clinical efficacy of sodium chloride (usually administered in daily doses of from 3 to 6 Gm in capsules) is undeniable. In some of their patients the results were astounding and in others were less remarkable. Another advantage of the saline treatment is the economy of cortical extract allowed. In less severe cases the extract can in fact be entirely reserved for complications, such as infections. The saline treatment is well tolerated in general. In some patients gastric disorders are produced. To avoid them the salt may be taken with milk or with sodium bicarbonate. Edema was observed in only one case.

- *Simple Method of Preparing Suspension of Choroid Pigment for Melano reaction of Henry in Malaria R Silvestrini—p 614

Melanoreaction of Henry in Malaria.—Silvestrini reviews the literature on the melanoflocculation reaction of Henry and describes a method of extraction with ether of the choroid pigment, which renders the reaction easy to perform. Henry's method is the following: After the crystalline lens has been removed the choroid of the ox is scraped and the gelatinous liquid and the melanin are collected. These are mixed, double the amount of distilled water is added and the whole is well triturated. Formaldehyde is added for preservation in the proportion of 1 per cent. A certain amount of precipitation may take place. Filtration is done through glass wool. The filtrate is centrifugated for eight minutes at 4,000 revolutions. The blackish supernatant liquid is decanted in sterile recipients and preserved on ice. It is vigorously shaken twice weekly and used after one month. The stock suspension is diluted to an opacity corresponding to that of a tube marked 0.20 of the albuminometric scale. Applying the method of extracting pigment from melanotic tumors by shaking the tumor fragments with ether, the author extracted in the same manner the pigment from the choroid of the ox to make the suspension for the reaction of Henry. He thus obtains the finest suspension of particles of pigment in ether. The ether in which the pieces of choroid are shaken is poured in a funnel with a stopcock at the bottom of which several cubic centimeters of physiologic solution of sodium chloride has previously been placed. The pigment is deposited and forms a layer between the salt solution and the ether. The stopcock is opened the salt solution and the pigment are collected and the ether is discarded. The pigment is shaken in the salt solution and is diluted with physiologic solution of sodium chloride until it shows a weak opalescence. The suspension is distributed in sterilized tubes and the serum to be examined is added in various proportions. With malarial serums the author obtained intense precipitations flocculating after two hours of rest at 98.6 F. If the tubes are observed for a long time, there is no need to take account of slight deposits at the bottom of the tube. Only the rapid intense and flocculating precipitation and the clarification of the liquid as compared with control tubes have a real value.

- *Anatomopathologic and Pathogenic Study of Diverticula of Duodenum L Minucci Del Rosso—p 236

Diverticula of Duodenum.—Minucci Del Rosso reports two cases. A woman, aged 61 had two diverticula and a man, aged 68, had a single diverticulum. On reviewing the pathology he found that there is no morphologic correspondence between duodenal diverticulosis and the classic picture of diverticulosis of the large intestine. The author states that duodenal diverticula in 90 per cent of cases are found between the second and the third portion of the duodenum and are limited to the duodenal segment corresponding to the pancreas. Islands of accessory pancreas are frequently found in the wall of the diverticulum. The dynamics of the development of the relation of duodenum and pancreas is extremely complex and involves both organs. The histologic structure of the duodenal tract even in the second and third portions, presents accessory diverticular invaginations during the first weeks of life. The author states in conclusion that extrinsic mechanical embryonic factors such as pressure on the part of the pancreas and torsion of the umbilical loop in certain cases may lead to the persistence of the characteristic diverticular formations which normally are transient.

- *Erythrocyte Sedimentation in Obstetrics and Gynecology D Taylor Gorostiaga—p 639
- Gastro-Intestinal Tract and Sympathetic Nervous System in Infantile Paralysis G P Góñalons—p 649

Hemiballistic Syndrome.—Alurralde and Sepich say that a clinical diagnosis of a degenerative lesion in the hypothalamic nucleus can be made by the presence of hemiballism and that the seat of the hypothalamic lesion in those cases is contralateral to the side of the body affected by hemichorea. The following symptoms are found. The patient is suddenly taken ill with hemichorea of a characteristic nature, followed by absence of sleep and appearance of mental disturbances. The choreic movements are violent, jerking and twitching and of exaggerated intensity, more marked at the root of the limbs than at the distal extremities. They increase in amplitude and frequency when the patient does not try to control them and entirely cease for the few minutes in which the patient can sleep if he is given some hypnotic and sedative. Both the mental and the motor symptoms are aggravated at night. The disease follows a rapid evolution and the patient dies in about six weeks from its onset. In the two cases reported, a clinical diagnosis of a probable vascular lesion in the hypothalamic nucleus causing hemichorea was made.

Erythrocyte Sedimentation in Obstetrics and Gynecology.—Taylor Gorostiaga performed the erythrocyte sedimentation test on 150 women in normal, gynecologic and obstetric conditions. He concludes that the increased speed of sedimentation may have several causes. The interpretation of the Fåhræus test should be based on the results of a careful clinical examination of the patient. The Katz index increases during menstruation in women clinically normal from 3 to 7 mm in 75 per cent of the cases. The speed of sedimentation increases in normal pregnancy at the end of the second month in 50 per cent of the cases, in the third month in 83.3 per cent and after the fourth month in 100 per cent. The test is not applicable to an early diagnosis of pregnancy. However, a speed increasing constantly during the test repeatedly performed indicates pregnancy. The speed of the sedimentation increases during the first month of normal puerperium in 100 per cent of the cases. It reaches its greatest rate by the ninth day after which it slowly decreases and reaches normal figures by the thirtieth or forty-fifth day of the puerperium. The speed of sedimentation is greater in puerperal infection than in the normal puerperium and it is in direct relation to the seriousness of the infection. The speed of sedimentation increases greatly in infected abortion and slightly in noninfected abortion, in comparison to that corresponding to the time of evolution of pregnancy. In all women who were subjected by the author to curettage after abortion, in spite of the presence of a high Katz index, the postoperative period was normal and the patients were discharged in good condition. The speed of erythrocyte sedimentation is normal in women with small or middle sized fibromas that have not undergone degeneration or infection or are not complicated by abundant hemorrhages, as well as in those who have an ovarian cyst, if its pedicle is not twisted. The speed of sedimentation increases slightly in adnexitis. As it is in relation to the evolution of the disease, the performance of the operation can be determined by the results of the test rather than by the curve of the fever. The speed of sedimentation increases in large fibromas and still more in pyosalpinx parametritis and Bartholinitis. In uncomplicated extra-uterine pregnancy the speed corresponds to that of normal pregnancy at the same period of evolution and it increases in complicated extra-uterine pregnancy. A differential diagnosis between either chronic or subacute adnexitis, on the one hand, and uncomplicated extra-uterine pregnancy on the other cannot be made by the results of the test as it is between the former condition and a peritoneal blood effusion from a ruptured extra-uterine pregnancy. A differential diagnosis between acute adnexitis and ruptured extra-uterine pregnancy can be made by the results of the test when the clinical examination of the patient excludes the presence of pyosalpinx.

Right Angle Triangular Shadow of Posterior Mediastinum Clinical and Roentgen Interpretation D Thamm F A Medici and C A Rey —p 918
Thalamic Syndrome Case. H R Rugiero —p 921
Ample Gastrectomy in Gastric Ulcer M J Taverna —p 952

Right-Angle Triangular Shadow of Posterior Mediastinum—Thamm and his collaborators say that the clinical diagnosis of the process that causes a right-angle triangular shadow of the posterior mediastinum to appear in the roentgenogram may be made by a differential diagnosis of the following conditions: adhesions of the middle and inferior lobes of the lung, costomediastinal pleuritis, pneumonia of any etiology, especially that described by Pospischin as a complication of whooping cough, bronchiectasis, atelectasis in bronchial compression by a ganglion of increased size, dislocation of the inferior lobe of the lung (Bernou), bronchial cancer, and encysted empyema. To make a differential diagnosis with exudative mediastinal pleurisy is easy, but to make it with costomediastinal pleurisy is difficult. In the case reported by the authors, the presence, evolution and disappearance of the clinical symptoms (presence of tubercle bacilli in the sputum and hemoptysis, which disappeared with the favorable evolution of the disease) coincided with the presence, evanescence and complete disappearance of a right-angle triangular shadow of the posterior mediastinum in the roentgenogram. A puncture at the base of the left hemithorax in this case gave negative results. The clinical diagnosis was tuberculous infiltration (epituberculosis), superficially located in the zone that corresponds to the left accessory lobe of the lung.

- Diagnosis of Carcinoma of Bronchus A Kenner —p 117
*Significance of White Blood Picture in Relation to Sedimentation Speed of Erythrocytes in Clinical Estimation of Some Forms of Pulmonary Tuberculosis G Thiele —p 126
Technical Improvements in Thoracoplasty R Noack —p 146

Diagnosis of Carcinoma of Bronchus—Kenner describes the chief clinical symptoms of carcinoma of the bronchus on the basis of observations in eighteen cases. He stresses the almost general occurrence of an accompanying chronic pneumonic involvement of the affected portion of the lung. He thinks that, if there is a chronic pneumonia of the indurating, abscess forming or gangrenous form, it is necessary to search for a stenosis of the pertaining bronchus. The concurrence of several accompanying symptoms, such as relapsing hemoptyses, stenotic respiration, or formation of collateral vessels in the skin, are of diagnostic significance.

The Leukocytes and Sedimentation Speed in Tuberculosis—Thiele compared the blood picture and the sedimentation speed of the erythrocytes in 100 male patients with open tuberculosis. Some had caverns, but in most the clinical course had a tendency to latency. The sedimentation values were normal or nearly normal, but the white blood picture showed considerable changes. All forms of leukocytes showed qualitative and quantitative changes in the majority of the cases, while in others only one of the types showed alterations. The total number of leukocytes was normal or increased, never reduced. The quantitative blood picture showed a considerable lymphocytosis, frequently in spite of a simultaneously existing deviation of the neutrophils to the left. The lymphoid cells likewise showed qualitative deviations from the normal. In cases presenting nearly normal neutrophil blood pictures, the lymphocytes were still strongly altered. In no case was the blood entirely normal. Discrepancies between the hematologic and the clinical aspects were frequent. The author gained the impression that a normal sedimentation speed and a normal, total number of leukocytes do not exclude the existence of caverns. The tuberculous process has been arrested only after the blood has become normal again. In the cases examined by the author, the blood picture proved superior to the sedimentation reaction as an indicator of the status of the pulmonary

process. It proved that a real arrest of the process had not taken place when this assumption seemed justified on the basis of the sedimentation speed and the other clinical aspects. The author rejects Schilling's "phases" and his interpretation of the hemogram, because they do not correspond to the real conditions. He thinks that for practical purposes it is preferable to use Arneth's simplified neutrophil blood picture, in which only the cells of the first class are determined among 100 neutrophils.

*Hypertonic Solution of Dextrose in Treatment of Increased Intracranial Pressure K Kamniker and W Sinnreich —p 239
Morphine as Premedication in Evipan Anesthesia K Vogeler and Kotroglu —p 242

Dextrose in Treatment of Increased Intracranial Pressure—Kamniker and Sinnreich report thirty-two cases of skull injuries treated with hypertonic solution of dextrose. The method consisted in slowly (from ten to fifteen minutes) injecting into a vein about 70 cc. of a 50 per cent solution in women and 100 cc. in men. The injections were given one day apart and an average of three injections was used. Twelve of the patients were rendered symptom free and fourteen were discharged as improved. In six there were no results. Three of these had sustained severe destructive brain lesions. The author concludes that the method is safe and valuable in lowering intracranial pressure. It is effective when the headache, stupor and dizziness are caused by rising intracranial pressure.

*Exophthalmic Goiter Thyroid and Vegetative Nervous System Neurovegetative Hormone System as Biologic Unit P Sunder-Plassmann —p 736

Neurovegetative Hormone System—Sunder-Plassmann was able to demonstrate, in his histologic studies, the existence in the cells of the thyroid of a "terminal reticulum" of the vegetative nervous system. This reticulum was traced as it proceeded from a cell of the vessel wall to an individual cell of the gland, where it spread out within the plasma and continued uninterruptedly in a close network so as to include all the cells in one functioning unit. The thyroid receives its nerve supply, according to the author, not alone from the superior cervical sympathetic ganglion but to a great extent from the three cervical ganglia, the superior laryngeal nerve, the recurrent laryngeal nerve, the carotid plexus, the cardiac branches and the glossopharyngeal nerve and from the walls of all the thyroid blood vessels. Resection of the sympathetic does not accomplish denervation of the thyroid. A more or less complete denervation of the thyroid would imply in addition to extensive resection of the nerves stripping of the thyroid vessels, the common carotid artery and the carotid sinus, or their treatment with phenol and trichlorol as advised by Cattaneo. A more or less complete blocking of the sympathetic innervation can be obtained temporarily by administering to an animal tartaric acid ergotamine. The author was further able to demonstrate that the thyrotropic hormone effect could be completely eliminated by administering to the animal a type of anesthetic which acted on the brain stem (solution of the sodium salt of secondary butyl-beta-bromallyl barbituric acid), thus proving that the vegetative nervous centers are located in the vegetative midbrain, which controls both the hypophysis and the thyroid. Experimental stimulation of the neurovegetative receptor areas in the carotid sinus produced a definite and pronounced stimulation of the functional and secretory activity of the thyroid. The reaction varied with the type of stimulus. These facts suggest that the neurovegetative hormone system is one individual biologic unit. The role of the nervous system in the activity of the thyroid as well as in the pathogenesis of thyrotoxicosis is of the greatest importance. A severe case of thyrotoxicosis represents a permanent irreversible alteration and is therefore best treated by subtotal resection of the gland. Sympathectomy, roentgen irradiation and medicinal agents are not effective.

*Follicle Hormone Content of Blood in Eclampsia W Bickenbach and H Fromme —p 496

Blood Pressure Reduction in Pyelovenous Reflux. K Liedholm —p 497

Elimination of Cevitamic Acid—Schroeder studied the elimination of cevitamic acid in healthy persons and in persons with various disorders (exophthalmic goiter, typhoid, cystitis, polyarthritis, tuberculosis, pneumonia, diabetes, carcinoma and other conditions) before and after the administration of cevitamic acid. His investigations indicate that during infectious diseases the consumption of cevitamic acid is often considerably increased. Other investigators likewise observed a gradual increase in the cevitamic acid content of the serum during the period of convalescence after sepsis and typhoid. The author deplores that he was not able to extend his studies to cases of capillary toxicoses and to other hemorrhagic diatheses, in which other investigators had obtained favorable results with the intravenous administration of cevitamic acid. However, he thinks that the prompt improvement often produced by the administration of cevitamic acid in the hemorrhagic diatheses developing after infectious diseases, as well as the result of his own investigations, make it appear probable that a hypovitaminosis (to be sure, on an endogenic basis) is an essential factor in the pathogenesis of the capillary toxicoses. He thinks that studies of suitable cases will furnish the definite proof of the correctness of his conclusions, and also that they may indicate why the predisposition to capillary hemorrhages is more pronounced in some cases. He points out that Presnell's observations on guinea-pigs correspond with his own, because this author observed that in case of a deficiency in vitamin C the coagulation time is prolonged and the number of erythrocytes and the hemoglobin are reduced before the appearance of the symptoms of scurvy.

Follicle Hormone Content of Blood in Eclampsia—Bickenbach and Fromme found that, in spite of the increased follicle hormone content of the urine of patients with eclampsia reported by Heim, even the extraction method, which they employed on the blood of four women with eclampsia, disclosed no noticeable increase in the follicle hormone content of the blood over the values observable during normal pregnancy.

Observations in Brain Surgery B Oton —p 483

*Refractory Case of Lambliaosis of Biliary Passages H Scheidel —p 485

Reduced Resistance Against Infections in A Avitaminosis M Frank —p 486

Insufflation of Uterine Tubes—Novak employs Rubin's technic of insufflation. The apparatus consists of a carbon dioxide tank from which the gas passes through a regulating valve into a glass volumeter. The gas is passed through sterile water and a boric acid solution or some other sterile fluid, and thus dust particles and other matter are removed. Then it passes through a sterile tube to an intra-uterine catheter introduced beyond the internal os. By means of a rubber cone that surrounds the catheter, the external os is closed airtight. The intra-uterine gas pressure is indicated by a manometer attached to the volumeter. In recent years a kymograph has been used and although this instrument is not necessary, it is a valuable aid. The author considers insufflation of the uterine tubes advisable in cases in which other methods of examination, including the examination of the woman's husband and of a specimen of semen do not reveal causes of sterility. If tuberculosis of the internal genitalia is suspected insufflation should not be done. The most favorable time for insufflation is immediately following the menstrual period. Before resorting to insufflation, the apparatus should be carefully inspected. Then the uterine cervix is drawn forward by means of a ball-

forceps. Dilatation of the cervical canal is usually unnecessary because it is usually permeable for an intra-uterine catheter. Anesthesia is unnecessary because the method causes little pain. Moreover, because the pain phenomena are of great diagnostic significance, it is undesirable to exclude them by anesthesia. The quantity of gas necessary for the insufflation is approximately 160 cc. The intra-uterine pressure should never exceed from 200 to 220 mm. of mercury. If the tubes are impermeable at the uterine ostium, the intra-uterine pressure increases rapidly and the patient complains of painful tension in the middle of the lower part of the abdomen. As soon as the pressure reaches 200 or 220 mm. of mercury, the attempt is given up and the gas escapes from the uterus. If the tubes are obstructed at the abdominal ostium, the patient experiences pains also on both sides of the abdomen, and the gurgling tubal sounds and the characteristic pains in the shoulder are absent. If at least one tube is patent, but so constricted that the gas penetrates only with great difficulty, the manometric pressure rises at first rather high and then recedes gradually. Occasionally insufflation produces a therapeutic effect in that it opens the obstruction and thus counteracts sterility.

Influence of Narcotics on Therapeutic Fever—Wehner points out that the extremely high temperatures in fever therapy are frequently accompanied by severe headaches, nausea, vomiting, pains in the muscles and joints, palpitation of the heart, dyspnea, insomnia and other symptoms, so that the patient demands the premature interruption of the treatment. For this reason it would be desirable to give the patients remedies that would reduce these symptoms. Antipyretics are inadvisable because, by reducing the fever, they would defeat the object of the fever therapy. The author decided to try different narcotics and she found that opiates and certain barbituric acid derivatives reduce some of the undesirable symptoms without interfering with the biologic action of the fever therapy.

Lambliaosis of Biliary Passages—Scheidel relates the clinical history of a man, now aged 54. The anamnesis indicates that symptoms which were repeatedly interpreted as being caused by cholecystitis date back seventeen years. The lambliaosis was not recognized until twelve years later. After that the patient was subjected to various therapeutic measures including treatment with neoarsphenamine and duodenal irrigations. Although a reduction in the number of the protozoa was followed by improvement in the disturbances, complete cure was not obtained.

*Epidemiology and Pathogenesis of Epidemic Acute Serous Meningitis H Schneider —p 425

Observation of Anomalies of Two Muscles on Living Persons G Sauer —p 430

Epidemic Acute Serous Meningitis—Schneider points out that the clinical aspects of serous meningitis, the so-called aseptic meningitis of Wallgren, seem to correspond partly to an abortive epidemic encephalitis and partly to an abortive poliomyelitis. He arrived at this opinion on the basis of necropsies in acute cases and of the after-examinations of former patients for, after an apparent recovery from the meningitis, symptoms of parkinsonism developed in some cases. He discusses the epidemiology on the basis of observations he made in the course of seven years in 150 cases. The disorder seems to confer an immunity, it is communicable and occasionally it is transmitted by carriers, who themselves remain free from it. In some cases the disorder seems to become manifest in two successive outbreaks. The disease is most frequent during the later part of the summer. The author points out that several of these epidemiologic factors indicate a poliomyelitic etiology of the serous meningitis. In a discussion of the necropsies he stresses that the histologic aspects likewise indicate relations to poliomyelitis. He describes the bacteriologic observations and points out that the term aseptic meningitis is unsuitable because it is contradictory. Bacteriologic studies of a number of patients disclosed various types of streptococci nonhemolyzing ones.

hemolyzing ones and some that produced a green zone. The author points out that some streptococci, among them the diplo-streptococcus that has been found in the brain of patients with epidemic encephalitis, are now considered saprophytes. It is known that some anaerobic organisms require symbiosis with saprophytes for their existence. In this connection he calls attention to the bacillus of tetanus, which requires for its growth the presence of aerobic bacteria that absorb the oxygen and thus produce anaerobic conditions. The virus of poliomyelitis likewise can be cultivated only under anaerobic conditions. The author cites evidence that makes a symbiosis of the virus of poliomyelitis with streptococci seem likely. He thinks that the atypical abortive course of poliomyelitis in the cases observed by him is due to the same cause. The high incidence of the disorder during the summer may be due to the fact that work in the hot sun produces a predisposition. In this connection it is pointed out that Japanese encephalitis is likewise most frequent during the hot season. Another factor is the possibility of the transmission of the virus in the dust.

Extragenital Lymphogranuloma Inguinale in a Nurse H Homma and H T Chaglassian—p 464

*Atrophic Cirrhosis of Malarial Origin O Serefettin—p 466

Chemistry of Urine in Carcinoma.—Weiss concedes that no method of urinalysis definitely demonstrates the existence of a malignant tumor but only makes its existence probable. Moreover, not a single pathologic aspect of the urine but rather the collective consideration of several aspects, is of diagnostic value. The author considers first the pigment elimination and the specific gravity of the urine of cancer patients. In cases of gastro-intestinal cancer, for instance, the urine may become relatively pale. The appearance of urochromogen in the urine is an early sign of some types of cancer, and a positive urochromogen test in an older person, who is free from fever, severe cardiac decompensation and tuberculosis, should make the physician suspicious of a malignant growth. The specific gravity of the urine of cancer patients may be somewhat reduced. Increased intestinal putrefaction, which is indicated by an indican reaction, the presence of urorrhodin, Thormählen's test that demonstrates the presence of indole-like substances or a test that determines the oxacids, often indicates the presence of gastro-intestinal cancer. The estimation of the mineral metabolism on the basis of urinalysis is valuable in determining cancer metastases in the bones. A reduction in the chlorides and an increase in the calcium indicate an endogenic origin of the calcium and consequently make probable the existence of bone metastases. In order to determine the presence of hepatic metastases, the author resorts to a method demonstrating the existence of tyrosine. He discusses the protein disintegration in cancer and emphasizes that there is no protein disintegration that is specific for cancer. He gives especial attention to the nucleo-albumin elimination in the urine and believes that the nucleo-albumins may favor the development of cancer. He discusses the significance of urinalysis for the detecting of changes in the ferment metabolism and admits that these studies on the ferment metabolism cannot be definitely evaluated as yet.

Atrophic Cirrhosis of Malarial Origin.—According to Serefettin, most authorities agree that malaria may lead to hypertrophy of the liver, but the possibility of atrophic cirrhosis is not so generally admitted. Some investigators suggest that malaria patients who develop atrophic cirrhosis are either alcohol addicts or are syphilitic. But there are some, particularly those who practice in paludal regions who agree that malaria may produce an atrophic cirrhosis. To the suggestion that alcoholism might be the cause, the author replies that his own observations, as well as those of other observers, were made on Mohammedan patients that is, persons who had never taken alcohol. Moreover, the patients were free from tuberculous lesions and the serologic reactions for syphilis were negative. In describing the symptomatology, the author states that the patients are pale, which differentiates them at once from those with alcoholic cirrhosis, who usually have a reddish appearance. Postmalarial atrophic cirrhosis is characterized

also by general weakness, anemia and emaciation of the extremities and of the chest, in strong contrast to the swollen abdomen. Then there is ascites, dilatation of the abdominal veins, and enlargement of the spleen so that it reaches beyond the umbilicus. The liver is not palpable, even following withdrawal of the ascitic fluid. The pulse is weak and accelerated and there are cardiac murmurs like those of anemia. The temperature fluctuates and occasionally reaches extremely high values. The urine contains urobilin, urobilinogen and bilirubin and, in some cases, also indican. The erythrocyte count fluctuates between two and three millions. Necropsy disclosed that the anatomic aspects of postmalarial atrophic cirrhosis differ somewhat from those of the alcoholic and the syphilitic type. The surface of the malarial liver is not so humpy and is less firm than in alcoholic cirrhosis. The connective tissue strands do not show an advanced development. The bile passages and arteries are not completely destroyed, and the process of degeneration is not advanced. If the patients have not reached a state of advanced cachexia, the condition is still amenable to treatment, and much better therapeutic results can be obtained than is the case in the alcoholic form. The author administers 1 Gm of quinine for ten successive days, then follows a pause of eight days after which the treatment is resumed for eight or ten days and, following another pause of seven days, the medication is resumed for six or eight days more. The diet should provide large quantities of vegetables and fruits, but the proteins, carbohydrates and fats should be restricted. The patient is kept in bed and the constipation is adequately treated. In order to compensate for the deficient hepatic function and to stimulate diuresis, liver preparations are administered. Many patients improve considerably under this treatment.

*Malariotherapy of Nonsyphilitic Nervous Disturbances During Childhood L von Dobszay and Ilona Fischer—p 124

Serologic Diagnosis of Whooping Cough.—Gundel and his associates describe a method of complement fixation in whooping cough. The antigen is a concentrated suspension of whooping cough bacilli in alcohol with the addition of lecithin, which they found highly specific. The reaction may become positive at the end of the second or third week after whooping cough has been contracted, that is, even before the onset of the typical coughing attacks. The reaction remains negative in cases with severe complications and in lethal cases. The percentage of unexplainable failures in definitely demonstrated cases of whooping cough amounts to 3 per cent. The authors state that they generally observed considerable antibody formation following vaccination with whooping cough vaccine. They observed also that the antigenic action of various strains of the bacillus differs considerably. In order to gain better insight into the immunologic processes, they made studies on the endotoxins of the whooping cough bacillus and succeeded in obtaining a highly potent endotoxin with a strong toxic effect for rabbits and mice. However, in its present form it proved unsuitable for purposes of immunization. Attempts to use this endotoxin for diagnostic purposes, in the form of intracutaneous tests, failed.

Malariotherapy of Nonsyphilitic Nervous Disturbances.—Von Dobszay and Fischer decided to try malariotherapy in early and late postencephalitic disturbances, in Little's disease, in idiocy and in epilepsy. They discuss their clinical observations and results. Malariotherapy proved entirely ineffective in five cases. Two of these children had the late form of the postencephalitic disturbance, two others were idiots and the fifth had true idiocy. Malariotherapy had definitely harmful effects in two cases. Three children, two idiots and one with Little's disease, showed slight improvement following the treatment. One child with genuine epilepsy showed great improvement and two children, in whom the postencephalitic disturbances were in the early stage, were completely cured.

The authors reach the conclusion that malaria therapy is justified in cases of severe, refractory disorders of the nervous system, particularly in those complicated by feeble-mindedness. They consider it most promising in the early stages of post-encephalitic disorders.

- *Diiodotyrosin and Compound Solution of Iodine in Treatment of Hyperthyroidism H. Gotta—p. 1
- Studies on Electrical Skin Resistance Following Sea and Sun Baths H. Meissner—p. 12
- Determination of Site of Development of Ventricular Extrasystole H. Baumann and A. Weber—p. 18
- *Action of Adrenal Cortex Extract on Cholesteremia C. V. Medvei—p. 58

Diiodotyrosin and Compound Solution of Iodine in Hyperthyroidism.—Gotta studied the efficacy of diiodotyrosin and of compound solution of iodine, because some investigators maintained that diiodotyrosin is more effective than compound solution of iodine, while his own studies had convinced him that the efficacy of the two preparations is about the same. From observations on twenty-six patients with hyperthyroidism, he reaches the conclusion that there is no difference between the action of compound solution of iodine and of diiodotyrosin. The differences that may be observed in the action of the two are merely the result of the order in which they are administered, that is, the preparation that is given first is most effective. The author discusses also the pathologic anatomy of the thyroids that were removed following treatment with iodine and reviews animal experiments. He summarizes his observations as follows: 1. Diiodotyrosin as well as compound solution of iodine produce in hyperthyroidism a temporary improvement that is followed by an exacerbation. The latter develops, no matter whether the treatment is continued or interrupted in the latter event the exacerbation develops earlier. In exceptional cases the improvement may be permanent, no matter which of the two preparations is employed. 2. There are cases of hyperthyroidism that are resistant to diiodotyrosin and the author found that these cases were likewise resistant to iodine. 3. Comparative studies on two groups of patients, indicating that the preparation which is given first is the most effective, convinced the author that the iodine of diiodotyrosin produces the therapeutic effect, for it is known that iodine, if administered with interruptions, loses its efficacy more and more. The author regards diiodotyrosin as a prehormone of thyroxine. Its regular occurrence in the normal thyroid and the biologic similarity and the chemical relationship between the two substances indicate this.

Action of Adrenal Cortex Extract on Cholesteremia.—Medvei points out that, while it is generally conceded that epinephrine, the active principle of the adrenal medulla, effects an increase in the cholesterol content of the blood, opinions differ about the effect on the blood cholesterol of adrenal cortex extract. Recent studies on B. avitaminosis disclosed that various modes of extraction of the active principle of the adrenal cortex result in products with slightly different actions. For instance, one product of the adrenal cortex, extracted by primary alkaline hydrolysis, was found to inhibit the hypercholesteremia as well as the reduction in the blood phosphatides of pigeons with B. avitaminosis, while another product, obtained by acid extraction, was also found to inhibit the hypercholesteremia but to promote the reduction in the phosphatides. The latter substance was found to aggravate the B. avitaminosis, while the first substance improved it. These and other observations seemed to indicate that adrenal cortex extract contains at least three distinct components. Attempts to isolate these three substances succeeded. Other authors searched for still other factors. The author studied the action of adrenal cortex extract on the cholesterol content of the blood of several patients with Addison's disease and he also made tests on persons free from endocrine disorders. He found that adrenal cortex extract that was prepared according to the method of Swingle and Pfiffner and contained no epinephrine reduces the cholesterol content of the blood in the majority of normal persons. Correspondingly a hypercholesteremia was found in Addison's disease. However, in case of hyperfunction of the adrenal cortex, normal

or subnormal blood cholesterol values were found. These observations correspond with the reports on epinephrectomized animals. The author observed Addison's disease in two siblings and considers this a new proof for the existence of a constitutional predisposition for this disorder, which he traces to a genotypical defect of the adrenals.

- *Treatment by Inanition in Disturbances of Urinary Tract. E. W. Gøthgen—p. 337

Treatment by Inanition in Disturbances of Urinary Tract.—According to Gøthgen, an absolute requirement in inanition treatment is that no sugar or carbohydrate in general be given, and a successful outcome of the treatment depends on the absence of complications. Because of its simplicity, short duration and high percentage of cures he advocates the treatment as the general method for hospitalized patients with pyuria and calls attention to the further advantage that a negative result almost certainly indicates a complication. The method is also considered a valuable feature in therapy after operations on infected urinary tracts, with possible significance in some cases in preoperative treatment.

- *Lamy Bile R. B. Engelstad—p. 407
- Roentgen Treatment of Pruritus Ani R. B. Engelstad—p. 411

Triboulet Reaction Controlled by Roentgen Examination.—On the whole there was agreement between the results of the Triboulet reaction and of roentgen examination of the intestine in Hertzberg's forty-six cases. He says that the Triboulet reaction is not specific and may be influenced by other nonspecific factors. While no roentgen symptoms are pathognomonic for intestinal tuberculosis, localization of the pathologic results about the ileocecal region is most important in the differential diagnosis in intestinal tuberculosis.

Hemolytic Fecal Streptococci (Enterococci).—Henriksen says that biochemical study of thirty-eight strains of enterococci, eighteen of which were hemolytic, showed that all the strains were heat resistant, gave low p_{H} concentration, grew in 30 per cent solution of bile and reduced methylene blue. All but one hydrolyzed sodium hippurate. Most strains fermented mannitol, sorbite and trehalose. Only two of the hemolytic strains were virulent in mice, and only two strains, both of the gamma type, were the probable cause of disorders in man. The author asserts that a relationship is established between the enterococci and *Streptococcus acidilactici* and points to the theoretical and practical significance of classification of hemolytic streptococci isolated from feces or other material.

Lamy Bile.—Engelstad states that, while calcium carbonate may be found in the gallbladder as a common component of gallstones, it may also appear as a special deposit as a stone or a milk-white fluid or a half-fluid mass. Because of the variation in color and consistency he prefers the term "Lamy bile" (Knutsson) to "milk of calcium" bile or calcium carbonate stones. In his case, with roentgen diagnosis confirmed on operation, the history pointed to a gallstone disturbance. The gallbladder, in addition to the dark brown, thick, tarlike Lamy bile, also contained a clear, thin hydropic bile and numerous concretions. There was an obstruction in the cystic duct. Obstruction of the cystic duct the author says seems almost always to be present in this condition and may perhaps assume a certain pathogenic role.

THE BREATH OF LIFE

PRESIDENTIAL ADDRESS

JONATHAN C MEAKINS, MD

MONTREAL

The text of my address will be found in the Holy Writ in the second chapter of Genesis and the seventh verse where it saith "And the Lord God formed man of the dust of the ground and breathed into his nostrils the breath of life, and man became a living soul" But in Flavius Josephus we read in the second paragraph of the first book that "God took dust from the ground and formed man and inserted in him a spirit and a soul" So here we see that there is apparently a close affinity between life, the spirit and soul. Already we find in the first chapters of Genesis that God had already commanded the waters to bring forth abundantly every moving creature that hath life and fowl that may fly above the earth in the open firmament of heaven. And He created great whales and every living creature that moveth, and let the earth bring forth the living creatures, and made the beast of the earth after his kind and cattle after their kind and everything that creepeth upon the earth after his kind. He commanded them to reproduce each after their kind, so having provided for the future of man "He breathed into him the breath of life" and made him a living soul.

This beautifully allegorical account of the Creation cannot but move us to admiration of the perfect historian who in a few clear-cut sentences outlines for those who follow after his conception of the beginning and way of life. But it must be noted that to man only was there given something of a special nature—all animal life was commanded to live, to reproduce, but the breath of life gave to man a soul.

A somewhat more comprehensive interpretation of the breath of life is undoubtedly to be found in ancient writings, but, to keep to the Holy Writ we find written in the fifth chapter of II Kings and the 34th and 35th verses how Elisha resuscitated the son of the Shunammite.

He went up, and lay upon the child, and put his mouth upon his mouth and his eyes upon his eyes and his hands upon his hands and he stretched himself upon the child and the flesh of the child waxed warm.

Then he returned, and walked to and fro and went up and stretched himself upon him and the child sneezed seven times, and the child opened his eyes.

This is the first recorded resuscitation by direct artificial respiration, the transference of the breath of life or the spirit of the soul of man from the holy prophet to the son of the Shunammite woman.

"Man does not live by bread alone" The members of the animal kingdom carry within themselves stores of most of their requirements, such as water, salts and food in the ordinary sense, but they have no stores of oxygen, without which life becomes extinct. In their development through the cons of time it seems strange that for this substance of imperative need there has been no mechanism evolved whereby a reserve might be accumulated. Even in those species which have a constant aqueous environment the acquisition of oxygen is a matter of the moment and is proceeded with incessantly to meet the continuous demands.

RESPIRATORY MECHANISMS

Respiration is commonly restricted to the intake of oxygen and the elimination of carbon dioxide by the lungs or their analogue. In a general way this is similar in all species in that the oxygen is acquired from the surrounding medium by diffusion through a more or less permeable membrane, on the internal side of which either the cell plasma or the blood transports it to living cells, where it now takes such vital part in their nutrition and life. These cellular activities may be termed "internal respiration."

It is now my purpose to review briefly the beautifully subtle manner in which the animal organism through its various phases acquires for itself this essence of life imperative for its survival and incidentally uses it for that love song, so to speak, with which to allure its mate for the perpetuation of its species.

UNICELLULAR ORGANISMS

I shall first consider the unicellular organism, which in a way may represent the component parts that make up the whole of the higher orders, which are but an aggregated although organized arrangement of cells separated anatomically by physicochemical interphases to make the tissues, organs and complicated structures of the higher mammals, and even unto God's image, as we are pleased to call man. For such a unicellular organism I shall select the humble but sometimes deadly ameba, which, although it may have some excretory respiratory faculty, acquires the essence of life by direct inward diffusion due to the negative difference in the partial pressure of oxygen between its internal and its external environment. If we can imagine such a small cell acquiring the source of life and power from the sludge that surrounds it, we can quite easily appreciate how the primitive multicellular animal developing in the primordial mud must have evolved some more efficient means of acquiring this breath of life. As they progressed into more complicated entities and the competition for propagation became more intense, they necessarily had to move faster and this demanded a more efficient method of locomotion than the plasmodial pseudopodia of yore. But increased movement requires an increased supply of oxygen. As by now the surface

membrane for protective purposes has lost much of that quality suitable for the diffusion of gases, some means must be provided for the acquisition of the breath of life, which is being required in increasing amounts. These means are ingenious and have numerous variations but in principle are more or less the same. In special areas the cuticle remains thin and delicate and may be a smooth surface or thrown into folds with indentations of varying complexity. These may be considered as rudimentary gills. Their situation differs from species to species but there is one more or less constant feature, namely, they are on or near the organs of locomotion. I might take as a good example the Isopoda, in which respiration is effected by the broad ram of the abdominal limbs. The renewal of the water, containing the oxygen, on the respiratory surfaces is brought about and accelerated by the movements of the limbs on which they are located, but often certain appendages bear special lobes adapted to set up a current under the shell or carapace and thus flush the chamber in which the gills are situated. So increased activity is served by serving itself. These are but slow moving creatures, although they do as best they can.

GILLS AND SWIM BLADDER OF THE FISH

As we proceed upward in the scale of development we find as the consumption of oxygen in the tissues is more rapid that there is an increasingly facile manner of acquiring it, until at last the medium containing it flows in increasing quantities past delicate membranes of vast area where freely circulates in capillaries the blood that is to acquire and carry the oxygen to the far distant cells to play an essential part in nutrition. This is well exemplified in the completely developed gills of the fish. These delicate organs perform a wondrous task and can meet changes in external environment in a manner to arouse our admiration. In lakes and oceans and deep bodies of water the oxygen held in solution decreases as the depth increases. But even at the best of times the concentration is low. The great handicap under which the aquatic animal is living may be realized when it is considered that a liter of air at ordinary temperature contains 210 cc of oxygen. A liter of water contains only 3 to 9 cc. This means that aquatic animals have at their disposal at the most in a liter of their immediate environment less than one twentieth of the amount of oxygen which an air-breathing animal has. To compensate for this, fish have a great capacity for extracting oxygen from the surrounding water and can do so even when the variations of concentration fluctuate acutely over a relative range to which an air-breathing animal could not possibly accommodate itself so rapidly.

In addition to gills, fish have another interesting organ, namely, the swim bladder, which in some has a respiratory function. This organ contains gases in practically the same proportion as in the surrounding medium and its contents usually vary with it. In most fish it undoubtedly is filled by physical diffusion, but in other cases there would appear to be an active inward secretion of gases. About this point revolves one of the important physiological controversies of the day. Can the human being secrete oxygen inward if exposed to suitable environmental conditions? On this question I shall not tarry, as the future holds the solution. To return to the swim bladder. In addition to such respiratory functions as it may have it acts as a hydrostatic

organ allowing the fish to volplane and loop the loop, dive to great depths and soar to the surface of its environment, and at the same time permits it to receive the triste song of its mate and to send her its call for one night of love.

THE AMPHIBIA

But we must pass on to the amphibia, from which we shall choose the humble frog, who in pollywog days has gills, but when he reaches his prime and becomes the basso profundo of his world he can breathe not only with his lungs but also through his skin, especially in those forms which hibernate in the mud. So he can adapt himself to the vicissitudes of his environment and still acquire sufficient oxygen for his humble needs.

BIRDS

From the waters we now soar to the firmament above and consider the streamline bird, which acquires the oxygen from the air through its lungs, which are relatively small, but this is compensated for by the bronchial tubes connecting with air spaces extending into the bones. The inspired air is thus distributed all over the body, so that aeration of the blood is not confined to the somewhat limited lung surfaces. This, however, serves another purpose by lending lightness and buoyancy to the frame. It helps the bird in its flight and rapid change of altitude.

MAMMALS AND THE EXPLOITS OF MAN

So finally we come to the mammals, the example of which will be man, whose external respiration is accomplished entirely through the lungs. He has no accessory or auxiliary respiratory mechanism. As the air is inspired it rapidly ventilates the lungs. This ventilation is so delicately adjusted and flexible as to maintain the oxygen content of the mean alveolar air at such a constant level under all ordinary circumstances as to saturate almost completely the hemoglobin, which acts as the oxygen reservoir for the blood plasma, from which the tissues obtain this breath of life. But this is not the only function of respiration. Biologic processes may at times seem wasteful, but if so there is a reason, if we can find it, which will reveal that it is the best under the circumstances and is accomplishing other functions vitally important for preservation or propagation. In addition to supplying the body with oxygen it eliminates carbon dioxide, removes water, helps to regulate the body temperature, is the fine adjuster of the chemical reaction of our internal environment which is maintained with remarkable constancy and, last but not least, serves us to tell our own story. If this were all it would be wonderful enough. But man has not been content to remain in his ordained surroundings. He has aspired to imitate the fish of the sea and the birds of the air. He is an envious and interfering creature, always poking his nose into other people's back yards, spying on their personal affairs out of pure curiosity, and to accomplish this he has used the ingenuity of Satan because he is not equipped by respiration to do it without danger to himself. The curiosity of Eve and the wisdom of the serpent have driven him onward, sometimes to his doom, in the name of truth and science. And the curious part of the whole thing is that he is succeeding.

When he aspired to invade the domain of the humble fish he thought the only thing necessary was to be supplied with the breath of life. But he soon found

that his finned cousin had power to stand variations in external pressure such as would crush him to a pulp. Furthermore, this respiratory business was not so simple. There were other things to be taken into consideration besides oxygen. The laws of physics have an uncomfortable way of being consistent. Although 80 per cent of the atmosphere is nitrogen and of no account in life, he failed to appreciate that it still obeyed these laws and diffused into the plasma in amounts proportionate to the increase in the partial pressure. So, when he returned from visiting his friend the fish in the depths of the sea he became acutely aware that all was not well within him. He found himself full of bubbles, in fact, he was like a soda-water bottle that has been suddenly uncorked, and he further found that air emboli have an aggravating way of "gumming up the works" so to speak, and the laugh was with the fish. But seeming defeat only made him more persistent. He found the reason and sought the remedy, which in common with most truths was simple. Instead of uncorking himself suddenly he learned to do it gradually so as to blow off his excess nitrogen at a safe rate. But this was a slow process and inaccurate, so he decided to do this with mathematical precision and found he could "de-gas" himself not only more rapidly but with greater safety. So now, having mastered his respiratory difficulties, he decided to visit his friend the fish and explore his habits and haunts whether he liked it or not. In fact, this Peeping Tom even took photographs without their permission and the final insult was moving pictures of their most private and intimate doings. Poor fish, your privacy is gone for ever!

Man, having conquered the depths of the sea, turned his attention to the bowels of the earth. Many of his engineering difficulties were inherent in the human factor. But survival in compressed air solved certain of these and permitted him to burrow like a rabbit. In order to satisfy his craving for speed and his avarice for the treasures of mother earth, he proceeded by exploratory operation and permanent anastomosis to expose her whole interior. Happily the earth worm and the gopher are not subjected to the indignities of the fish.

Since the beginning of time, man has been envious of the bird. Envious of its freedom! Envious of its flight! Although he could burrow in the earth and swim in the sea, he could not fly, so his soul was depressed and his spirit angry. Again defeat spurred him on until at last like the fledgling he made his first clumsy and blundering flight from his nest on earth. Now he had in his hand the possible means to outfly and outsoar the bird and within a few short years this had been done. But he soon discovered that respiration put a limit to his ambitions. As he soared like the falcon into the eye of the sun, he found there were limitations not of his machine but within himself in that the breath of life seemed to leave him. The atmosphere was there—it supported his birdlike structure but it could not support him. The explanation was not far to seek. With the increasing altitude the partial pressure of the atmospheric gases steadily declined until finally that of oxygen was not sufficient to penetrate the alveolar walls to saturate the plasma and hemoglobin in sufficient amounts to support life. Realizing that it is not the percentage of a gas which

determines its rate of diffusion, but its partial pressure which is the sum of its concentration and barometric pressure, man decided to increase the former as he could not alter the latter. So, with his oxygen tank and respirator he found the means to overcome his respiratory limitations.

INTERNAL RESPIRATION

Now we must leave external respiration and travel with the hemoglobin and its load of oxygen along the labyrinth of the arterial tree to the cells of the body. It must be clearly remembered that these obtain their oxygen from the tissue fluids surrounding them and these in turn receive it from the plasma of the blood with which it is in physical equilibrium. The amount of oxygen used by the tissues is in direct proportion to the amount of work done although some tissues require more than others. As the oxygen in the tissue fluids and plasma is consumed it is immediately replenished from the oxyhemoglobin, the dissociation of which occurs with great rapidity. We are now back to the unicellular organism again. Whereas the ameba had to seek for the breath of life where best he could, our cells have it brought to them ready to use with the least effort on their part.

What do they do with it? This brings us to life itself.

We must remember that in the structure of any organism, no matter how complex, the one purpose that is rigidly adhered to is the maintenance of a continual supply of energy to the individual cell.

Our ancestors, with considerable justification from an imaginative standpoint, compared life to a flame. The contemplation of an open fire with flames of different form, color and intensity is impressive from the ever varying, unordered and uncontrolled changes taking place. How similar are the processes of life! No living thing is absolutely still, alterations in position relative to environment, alterations in form, in growth and finally changes in the atomic and molecular structure make for ceaseless activity, and just as the changes in a fire are physicochemical so also are the changes in living matter physicochemical.

The power to live, the power to work, is not in the brain or in the body, just as in a machine the power is not inherent in the pistons, valves and fly-wheels. The power of living matter or machinery comes from without. What is this energy, how is it made available and how does it operate in living matter? Of the total energy of the universe part is available for work (free kinetic energy) and part not directly available. Our struggle for existence, as Boltzman has put it, "is the struggle for free energy."

What is our source of energy?

Firstly, plants act as the transformers of the kinetic energy of sunlight, converting it into the potential energy of carbohydrates, fats and proteins.

Secondly, to understand how this energy is made available to the individual cell is to understand the fate of the foodstuffs following ingestion and the changes undergone during digestion, absorption and assimilation, which will be discussed by Dr McLester.

Lastly, it is following the liberation of this potential energy in the animal organism that the internal respiration has its function.

Our modern conception of calories, combustion, and the fine values of foodstuffs has brought the idea of

oxidation and heat production so much before our minds that we are apt to consider our bodies as a sort of glorified steam engine puffing laboriously through life on the caloric equivalents of breakfasts, lunches and dinners. The fallacy of this conception is shown by a brief consideration of Carnot's equation, whereby it can readily be shown that, if the liberation of energy in our bodies took place by the conversion of foodstuffs to heat with a working efficiency of 25 per cent, then the temperature of the heat source would have to be 116 C or, in other words, at a temperature of 69 C above the lethal point. It is quite evident then that, when we convert bound energy into free energy, conversion of foodstuffs into heat is not one of the steps. It is not known how living material is able to convert the chemical energy of foodstuffs into mechanical energy, but one thing we are sure of—the liberation of energy in the animal is invariably followed by oxidation, and this oxidation takes place on or in the surface of the cellular units.

Our entire respiratory mechanism with its colossal surface area of more than 100 square meters and a red blood cell carrying surface of more than 3,000 square meters exists for and is controlled by the demands of the tiny individual cells. The breath of life is oxygen, the seat of life is the cell.

REPRODUCTION

I have already mentioned that most of the functioning systems carry out multiple tasks. This is one of the beautiful economies of the animal organism. As respiration is essential for the life of the individual, it is not surprising that it should play a part in arranging for the generations to come. It is true that this may be considered merely an accessory function but without an important one in the propagation of the species. The most primitive song of love has not as yet been recorded but we do know that in certain coelenterata of the free-swimming variety there are ostocysts, called by more recent authorities statocysts, as they are considered to serve a greater purpose for equilibrium than for hearing. That they serve both purposes there can be little doubt. The call of the earthworm we do not know, nor that of the fish, but there is ample evidence to show that the gaseous swim bladder is used both for sending and for receiving messages. Time does not permit mention of other species, but we cannot pass by that troubadour of the early summer night, the bull frog. Who has not listened to his song and the answering chorus from afar? He takes no chances. Being of the amphibians, he sits at the water's edge and sends his stentorian basso through both the water and the air so that all may hear. His song is as sweet to the fortunate who understand as is that of the "blithe spirit" of which Shelley sang, or the serenade to the lovely maiden as she sits behind the balcony screen in old Seville. The breath by which life is maintained does its part to ensure that this spirit may be carried on in future generations.

CONCLUSION

Now I hand over the future of man to my esteemed colleague and friend Dr. McLester. But before closing I wish to express to the officers and Fellows of the American Medical Association, on behalf of myself and my countrymen, our deep appreciation of your kindness in having us as your guests and I extend to you our thanks for your gracious hospitality.

NUTRITION AND THE FUTURE OF MAN

PRESIDENT'S ADDRESS

JAMES S. McLESTER, M.D.
BIRMINGHAM, ALA.

Man's place in future history will depend in no small degree on the food he eats. The truth of this was fore-shadowed about two decades ago when it was discovered that an animal's life processes may be profoundly disrupted by the omission from its food of any one of a number of substances, each of them ridiculously small in the amount required. Today there has been added the further, highly significant, observation that under certain circumstances an animal's life may be greatly improved by the addition of appropriate foods to a diet that previously had been regarded as entirely satisfactory. Through this knowledge, physiologists have been able to influence to a surprising degree the life history of their experimental animals and in some instances so to improve the stock as apparently to produce a new species.¹ Can this be applied to man? Can man, by giving thought to the food he eats, influence the destiny of his race? There is reason to believe that he can.

IMPROVEMENT OF RACIAL STOCK THROUGH DIET

Improvement of the stock as a result of betterment of the diet has been observed repeatedly both in the lower animals and in man. Among the earliest experiments in this field were those of Osborne and Mendel, who were able to show that what had previously been regarded as normal weight for the albino rat was not a fixed figure but was subject to material increase with improved nutritive conditions. The previously accepted standard weight of this experimental animal at 100 days of age, as established by Donaldson in 1906, was 165 Gm, but a few years later, under improved nutritive conditions, the standard for rats of that age was raised to 200 Gm, and within another decade to an average weight of 315 Gm. In this series of experiments the increase in weight of the albino rat, beginning at 2 Gm a day, was raised first to 4 Gm and finally to 6 Gm. Thus, during a period of twenty years, under conditions that were not varied except for improvement in the ration, the rate of growth of these animals was trebled and the standard weight for the species was about doubled. This improvement has not been limited to mere increase in bulk, for there has been concomitant improvement in all phases of physical development, including growth of the bones and inner organs and, according to Sweezy,² changes in cellular structure. It should be emphasized that the earlier generations of rats on which these studies were begun were living on rations that at the time were apparently suitable, and that it was by reconstruction of a supposedly adequate diet in accordance with newly discovered nutritional principles that this improvement was effected. It would appear that, by intelligent improvement of the animal's nutrition through successive generations, there has been developed a new species of albino rat.

Is the increased rate of growth of these animals to be regarded as wholly favorable? Most physiologists

² Smith A. H. and Bing F. C. Improved Rate of Growth of Stock Albino Rats. *J. Nutrition* 1: 179 (Nov.) 1928.

² Sweezy quoted by Smith A. H. *Yale J. Biol. & Med.* 4: 551 (March) 1932.

answer yes, but McCay³ states that such forced development, as he regards it, is not compatible with longevity. He believes that such animals age early and die prematurely. Against this criticism, Cowgill offers the pertinent suggestion that the increased metabolic needs of the more rapidly growing animals of McCay's series were possibly not met by commensurate increases in certain essential substances, and that under such circumstances a relative deficiency, with nutritive failure and consequent early senility, would necessarily follow. Of like import is the experience of Sherman,⁴ who has observed that when an apparently adequate diet is enriched in certain of its chemical factors by an increase in the proportion of milk there results not only an increase in the rate of growth but also an improvement in vitality and in the animal's average length of life. It is well known that increased vigor and sustained longevity are among the notable accompaniments of improvement in an animal's ration. It can safely be said therefore, that the experiences of other physiologists are not entirely in accord with those of McCay and that the preponderance of evidence indicates that the increased growth achieved by well considered improvement in the diet is accompanied by general physiologic betterment and definite improvement of the species.

IMPROVEMENT IN CHILDREN OF IMMIGRANTS

Have comparable changes, the result of improved living conditions, been observed in man? Yes, anthropologists tell of similar changes, which, while not so graphic as those seen in the lower animals, are none the less significant. Witness the report of Appleton⁵ that Chinese living under improved nutritive conditions in Hawaii grow to greater stature than people of the same racial strain in China, and that their growth continues to a more advanced age than does the growth of those remaining in the less hospitable homeland. The average height at 20 years of age for the group studied in Hawaii was 1.1 inches greater than that of similar groups in the ancestral province of Kwantung. A similar report from Kanzaki⁶ tells that children born of Japanese living in California show definite superiority in height, weight and other characteristics over their immigrant parents. The same can be said of other races who have emigrated to America, for it is of frequent comment in the larger American cities that children born in this country of European parents are of larger stature and better physique than their forebears. It is a common observation in medical schools that the Jewish students of European parentage who apply for admission are strikingly superior in physical attributes to their parents. The anatomist Todd⁷ has recently commented on changes of the form of the head seen in the children of immigrants, and of other changes which would indicate that the improvement in physique that is now being observed is not limited to mere increase in stature but is also an expression of better general development.

RESULTS OF HYGIENE AND IMPROVED NUTRITION

Such improvement in racial strain is not limited to those peoples who emigrate to more favored lands for like superiority of development is seen to accompany

better living conditions among the children of natives both in this and in other countries. Witness the studies of children from different social groups in this country made by Gray and Nicholson⁸ in Eastern private schools and by Faher in San Francisco, indicating that those of the more favored groups grow to a greater height. Of 4,000 women students who have entered Stanford University during the past thirty years, Mosher⁹ found that, although the average age of women coming to the university today is less than formerly, the average height has increased a little more than 1 inch. She believes that the changes reported by her point to a more fully developed and more perfectly functioning type of American woman. Similar reports come from England. The anatomist Parsons,¹⁰ of the University of London, believes that hygiene and better nutrition have undoubtedly raised the height of upper class Englishmen, in illustration of which he cites the fact that while the average height of the modern English working classes may be taken as 5 feet 5 inches (165 cm) that of the more well nourished group is definitely higher, the average among medical students being 5 feet 9 inches (175 cm). Of like import were the observations of Mann, undertaken for the British Medical Research Council, to the effect that, on the ordinary diets assumed by medical men to be proper for healthy development, the boys studied by him did not reach the full physical or mental growth of which they were capable, and that it was only when these diets were supplemented by milk that the best growth was attained. Similar evidence was seen in the more rapid growth observed during the large-scale experiment of distributing free milk to the school children of the Scottish county of Lanarkshire. Thus it is evident in man as in the lower animals that improvement in a diet that previously had been regarded as adequate will often result in a larger stature and a higher degree of development.

It should be emphasized, however, that larger stature is not the sole advantage that comes from improvement in diet, for there is abundant evidence that greater physical efficiency also follows. This was shown in a recent observation¹¹ that, of 160 English school children selected to compete in athletic events, 87 per cent of the winners were above the normal for height and weight and only 6 per cent below normal, and that the winners showed a proportion of overweight three times that of the seconds, thirds or "also rans." From the English air service¹² comes the report that athletic prowess and the capacity to endure physical stress, except in long distance events, was found most commonly in overweight men and that men who are underweight on joining the service are more often invalidated out than are those who are overweight. From Japan there was issued a public health bulletin¹³ stating that, when groups of Tokyo school children were given milk as a supplement to the diet, not only was greater increase in weight and height observed but these children were more cheerful and happy and showed greater prowess in athletics than did those of the control groups. Experiences such as these have brought physiologists

to the realization that a diet which appears to be adequate is not invariably the optimum diet. Far from it. In this connection Sir Frederick Hopkins¹⁴ writes:

The mere survival of a community, for instance, is too often taken as proof that the nutrition of its constituent individuals is adequate, lack of health or efficiency being attributed to racial or other uncontrollable factors. In social-economic surveys a race or community is found in equilibrium with an environment which includes its food supply. It is often forgotten that such environment is fortuitous and that the equilibrium reached is one in which the community, while managing to survive, may yet be functioning at levels far below those possible to its innate capacities. During the whole of history the needs of nutrition and the kind and amount of foods geographically available have played a great part in determining the destiny of races. Inadequacy in the supply has in some cases stunted innate capacities and led to the degeneration of a race. More generally in the past it has stimulated effort and led to migrations and wars of aggression.

In nutrition the words adequate and optimum are seldom synonymous.

INFLUENCE OF HEREDITY AND ENVIRONMENT

Such statements would seem to deny the influence of heredity, but this is not true, for heredity and environment are both of influence. The two combine to shape man's destiny. The truth of this is seen in those instances in which inherited characters have been profoundly altered by environment. This applies to details of structure as well as to other physical attributes. Witness the great sensitiveness to nutritional disturbances exhibited by the growth centers in the bones of the face. In infancy nutritive deficiency has its effect on the transverse and anteroposterior dimensions, while after five years retardation of vertical growth is most apt to occur. This explains the changes in the shape of the face which Broadbent has demonstrated in malnourished infants, and the difference in facial expression observed by Boaz between the foreign born and the American born children of immigrant parents. While the exact type of structural change produced by nutritional failure depends somewhat on the nature of the deficiency, it is a rule that malnourished children, as was observed by the Bakwins,¹⁵ suffer more in the growth of their transverse than in their longitudinal dimensions. The long bones continue to grow and there often results a thin individual with a misshapen chest and a gaunt, lanky appearance. This was beautifully stated by Todd,⁷ when he wrote "The adult physical pattern is the outcome of growth along lines determined by heredity but enhanced, dwarfed, warped, or mutilated in its expression by the influence of environment in the adventures of life."

This influence of environment is far reaching. Under unfavorable environmental conditions the development of a person's finer qualities are sometimes seriously retarded, while, on the other hand, under optimal circumstances his less fortunate traits may be mitigated. Even his period of usefulness may be greatly extended. One may accept Warthin's view that man's span of life is fixed by inheritance and is unchangeable, but "lives there a man with soul so dead" who does not ardently desire some means by which within his allotted span he may lengthen the years of his usefulness. There is evidence, as was recently emphasized by Sherman,⁴

that this can be done, that by improvement of a diet that already is apparently adequate man's prime of life, in both directions, may be considerably extended. The hastening of maturity may not be of interest to many people, but the postponement of senility through betterment of the diet is an alluring thought to every one.

THE GOSPEL OF GOOD FOOD

If such is the influence of environment, it should be possible through improved nutrition to bring mankind to a higher level of physical development. How is this to be accomplished? In this respect the American people are not indifferent. Indeed, they are acutely food conscious and will eat anything that they are told is healthful, but to teach them what they properly should eat will require the combined efforts of a great many people, notably the teacher, the physician and the publicist. In addition, in order that people may, within the means at their disposal, get the foods they need, there must also be elicited the help of the economist and the law maker.

Education comes first. Health education by means of nutrition classes such as is being carried on in the public schools of my own and of other cities can be expected to pay big dividends, for not only are the pupils themselves helped but these children carry the gospel of good food into the home and eventually elevate the nutritive standards of the entire family. It is a hopeful sign, too, that the physician himself is taking an infinitely greater interest in the science of nutrition than he has shown in the past. He can be expected to give to his patients dependable information which will eventually percolate throughout the community and bring widespread good, but unless he is also something of an economist he is apt to make the mistake at times of prescribing foods that the family budget will not afford. It is not sufficient, therefore, that the physician interest himself merely in the science of nutrition. He must study also the economics and distribution of foods and be prepared to prescribe diets that not only meet the patient's physiologic needs but also are within his easy reach. The necessity for the wider dissemination of such knowledge is seen in the fact that a great deal of malnutrition comes from the unenlightened selection of foods made by the housewife with a rigidly restricted budget. It is unfortunate that many of the cheaper foods, such as the potato, which carry the greatest number of calories and have the highest satiety value, fall far short of providing in sufficient quantities such essential food factors as vitamins, minerals and good proteins. Vitamins and minerals can be obtained in abundance in fruits and vegetables, while proteins of high biologic value are found in meats, eggs and milk, but these are all among the more costly foods. The important thing, therefore, is to know how in an economical manner to use these other more costly articles in order to supplement the less expensive foods. The experiments of Mendel and Osborne, and later of Cowgill and associates,¹⁶ would indicate that the cheaper cereals can still be used as the mainstay of the diet provided properly selected supplementary foods, such as liver and lettuce, are added in suitable amounts. In the effort to secure economical but well balanced diets Cowgill believes that, if sufficient intelligence is devoted to the selection

of these supplements, man can use cereals to a greater extent than is common today in this part of the world. It is because of its high supplementary value in a diet of cereals as well as of other foods that nutrition experts as a rule insist that a place be provided in the budget for definite quantities of milk and milk products. Even with today's high prevailing prices milk is still a bargain in food values. Thought must always be given to the protein allowance, too, since animal experiment as well as observations on man, such as those of Youmans in Tennessee, would indicate that protein is often the limiting factor in these cheaper diets. It is a function of the physician and the educator, then, to teach people the proper use of the protective foods in supplementing the cheaper diets.

IMPORTANCE OF FOOD HABITS

The food habits of a people are determined to an enormous degree by custom. What is commonly regarded as a diathesis or familial predisposition not infrequently, as has been pointed out by Cowgill, is an expression of the faulty food habits of the family. So dominating are the tabus and customs of a family or race as regards their food that these sometimes assume all of the force of mores. If the food habits of a people, because of poor supply, religious prejudice or other reason are grievously at fault, in all likelihood these will be accompanied by a gradual deterioration of the family or race, if, on the other hand, these habits are good, this circumstance will be reflected in more advanced physical development, greater longevity and a higher level of cultural attainment. Here in America where so many foreign groups have brought with their Lares and Penates their food habits as well, racial customs must be taken into consideration. If these customs are good, the physician in offering advice must accept them, if they are faulty, he must endeavor by education to combat them.

POLITICAL AND ECONOMIC FACTORS

I do not wish to discuss the political implications of my subject, but it must be recognized that any plan that proposes to elevate racial standards by means of improved nutrition must give serious consideration to political and economic factors, for in the carrying out of such a plan food must be produced in adequate amounts and marketed at a price that the public can pay. It is difficult to estimate how many persons in this country are so poor that they are unable to purchase the food necessary to keep them in health, but if one takes the criterion adopted by Orr¹⁷ in discussing the identical problem in England and assumes that those living on relief belong in this category, it can be said that something like twenty million American people are living near or below the threshold of nutritive safety. This condition, if continued, will surely affect the health of the race. The income of these people must be raised or the price of food lowered.

To make agriculture profitable to the extent that a good rural population can be maintained and at the same time the rest of the population supplied with cheap food is a problem that confronts the nation. This is a subject for economists to discuss, but I should like to call attention to the report of the Elgin Committee, appointed to determine a National Agricultural policy for Scotland¹⁷. After offering the familiar advice that

methods of distribution be so reorganized as to reduce the wide and growing difference between what the consumer pays and what the producer receives, the committee concluded that "it is in the interests of the state that the price of food should be kept so low that the poorest can obtain an adequate dietary." Adequate nutrition, then, is in the last analysis a problem of education and of government.

MASTERY THROUGH SCIENCE

In the past, science has conferred on those peoples who availed themselves of the newer knowledge of infectious diseases better health and a greater average length of life. In the future it promises to those races who will take advantage of the newer knowledge of nutrition a larger stature, greater vigor, increased longevity and a higher level of cultural attainment. To a measurable degree, man is now master of his own destiny, where once he was subject only to the grim hand of Fate.

THE DANGER OF GANGRENE OF THE TOES

IN THROMBO-ANGITIS OBLITERANS AND ARTERIO-SCLEROSIS OBLITERANS

NELSON W. BARKER, M.D.
ROCHESTER, MINN.

In spite of warnings by Buerger,¹ Brown,² Allen and others, the vulnerability of the toes of patients with peripheral occlusive arterial disease has not been sufficiently emphasized. At the Mayo Clinic, approximately 20 per cent of such patients have definite gangrene of the toes or feet on admission. In a series of 171 consecutive cases of thrombo-angitis obliterans in which the patients when first seen had definite gangrene of the toes or feet, ninety-four patients (55 per cent) stated that the gangrene had occurred spontaneously, and seventeen (10 per cent) stated that it had followed accidental, mechanical or thermal trauma, on the other hand, sixty (35 per cent) stated that it had followed therapeutic procedures instituted for painful toes or feet when gangrene or ulceration had not previously been present.

These figures are still more appalling when it is added that thirty-two, or more than 50 per cent, of the patients in the latter group lost their legs subsequently because of this gangrene which had been induced by treatment. Similarly, in 115 consecutive cases of arteriosclerosis obliterans in which patients had gangrene of the toes or feet, accidental trauma had been the inciting cause in nineteen cases (17 per cent) and therapeutic procedures in forty-five cases (39 per cent), in twenty-eight cases in the latter group, amputation of the leg was necessary.

A more detailed analysis of these cases of traumatic gangrene and gangrene induced by treatment is worthy of consideration. In table 1 are given the known accidental causes of gangrene. It is possible that this number would be swelled considerably from the group of spontaneous gangrene if more information had been available. There is a certain amount of trauma to the

feet in walking, particularly if the patient's shoes do not fit well. Minor contusions, small blisters and chilling may have passed unnoticed by the patient.

In table 2 are listed the causes in this series of cases of gangrene induced by treatment. Seven of the sixteen corns and calluses were removed by chiropodists. All of the other surgical procedures were carried out by physicians. The first three chemicals were suggested by druggists, the remainder by physicians. Eight of the ten burns were sustained in hospitals. Thirty-three of the forty-three toenails removed in part or in whole were from the great toe, and eleven of the sixteen corns removed were from the fifth toe. For anatomic reasons, one or the other of these two toes usually suffers most from ischemia in a given case and is therefore the most vulnerable. Five of the chemical and four of the thermal burns involved the entire foot. It would seem that in these cases the physicians who treated the patients had failed to recognize the presence of arterial disease or else were unaware of the hazards of such local treatment in the presence of arterial insufficiency.

The end results in the 105 cases of gangrene induced by treatment are given in table 3. In the cases of thrombo-angitis obliterans, half of the amputations of the leg were done at the clinic. In these cases conservative treatment was carried out for a considerable period of time, and the leg was sacrificed only because of extensive and progressive death of tissue or because of uncontrollable pain. In those cases in which healing took place without amputation, the period of disability ranged from one month to four years in the majority of cases lasting from three to nine months. Making all allowances for the possible development of spontaneous gangrene, if the original surgical, thermal or chemical trauma had not occurred, the price in time, money and loss of limbs which these patients paid for well intentioned but misdirected treatment was truly great.

In order to understand why gangrene occurred so easily, it is necessary to review the pathology and pathologic physiology of occlusive arterial disease of the extremities. In the majority of cases localized, occlusive arterial lesions occur periodically. Between

ischemia, even slight trauma to the toes is a serious event. Minor bruises, irritation from rubbing of shoes, moderate exposure to cold, and even the pressure of weight bearing that occurs in simple walking may be just enough to destroy cells that are poorly nourished and poorly oxygenated and start the gangrenous process. It is quite possible that in many cases what is considered to be spontaneous gangrene has such an origin and that there is really a traumatic factor in its

production. How much more serious, then, is a surgical wound that destroys part of the blood supply, which already is poor, and increases the risk of bacterial infection of badly devitalized tissues. How much more serious is a thermal burn to tissues which are barely surviving at optimal temperatures or a chemical burn to tissues in which there is already a profound disturbance of tissue chemistry. Once the gangrene has started, it may spread with alarming rapidity even beyond the toe to the foot itself, and the conservative treatment of peripheral occlusive vascular disease with frank gangrene is likely to be long, discouraging, expensive and not always successful.

Although the development of gangrene is a serious event in thrombo-angitis obliterans, it is even more serious in arteriosclerosis obliterans. In arteriosclerosis obliterans the occlusive arterial disease is likely to be more progressive and the collateral circulation develops more slowly than in thrombo-angitis obliterans. In the former condition the tissues of the toes and feet have a lower vitality, less resistance to trauma and less ability to heal ulcers, even in the presence of a blood supply that is only moderately limited than they do in thrombo-angitis. Arteriosclerosis obliterans is some times complicated by diabetes mellitus (as it was in a fifth of the present group with gangrene) and, if so, the spread of the gangrene is likely to be much more rapid and secondary infection is likely to be much more common. A rapidly spreading cellulitis of the leg and septicemia may occur and be followed by death.

The patient who is suffering from marked ischemia of the toes which has resulted from an active phase of thrombo-angitis obliterans or arteriosclerosis obliterans usually consults a physician because of severe pain which results from the ischemia of digital tissues and nerve endings. He may have ingrown toenails, corns, trichophytosis or red swollen toes that appear to be infected. Possibly the ischemia has greatly aggra-

TABLE 1—Gangrene Induced by Accidental Trauma

Total	17	19

these episodes are varying periods of quiescence during which the compensatory collateral circulation increases slowly. During active periods of the disease, and dependent somewhat on the extent and localization of the occlusive arterial lesions, many of these patients suffer from marked degrees of ischemia of the toes. Sometimes this ischemia is enough to cause spontaneous gangrene. Sometimes the tissues of the digit are perilously close to death but if some form of additional trauma does not occur they will survive until the collateral circulation increases the blood supply well beyond the danger limit. During periods of marked

verted the pain of an old corn or ingrown toenail. Most physicians frequently see corns and ingrown toenails in feet that have a normal blood supply, but they do not frequently see cases of thrombo-angitis obliterans and arteriosclerosis obliterans. However, in a case in which there is a painful toe or a lesion of the toe, regardless of how apparent the cause may be, it is a comparatively simple procedure for the physician to assure himself that pulsations are present in the dorsalis pedis and posterior tibial arteries, that there is no abnormal pallor of the toes after elevation of the foot, or that there is no delay in return of color on suddenly bringing it to a dependent position after elevation. He should also beware of an "inflamed" toe that is cold. Abnormal color of feet or toes, whether pallor, rubor or cyanosis, should excite suspicion of arterial disease. If there is evidence of deficient arterial blood supply, which was very easily demonstrated in all of the cases in this series, it is a safe rule to avoid all minor surgical procedures and to avoid all local applications except possibly warm foot-soaks of boric acid solution (not over 103 F). In such a case the patient should be kept off his feet. The affected foot should be kept warm with heat at a distance, and measures to increase the circulation to its maximal extent should be the principal therapeutic consideration.

It is commendable that newer methods of treatment, such as sympathetic ganglionectomy and the various medical vasodilating procedures, are definitely reducing the incidence of gangrene and amputation of the leg in thrombo-angitis obliterans. No small credit is also due to education of the patient regarding the nature of his disease and how to give his feet the maximal protection. If well intentioned surgical, thermal and chemical trauma to ischemic toes can be avoided, the incidence of gangrene will be lessened much further.

SUMMARY

In cases of peripheral occlusive arterial disease, the toes are extremely vulnerable and gangrene may easily be induced by even mild degrees of injury. In a

TABLE 3—End Results in Cases of Gangrene of Toes or Feet Induced by Treatment

series of 171 cases in which gangrene was associated with thrombo-angitis obliterans, the gangrene followed therapeutic procedures on the toes in sixty (35 per cent), and in a series of 115 cases in which the gangrene was associated with arteriosclerosis obliterans, the gangrene followed therapeutic procedures in forty-five (39 per cent). These procedures consisted chiefly of removal of ingrown toenails, less commonly they consisted of removal of corns, incisions for suspected abscesses, thermal burns, and irritations resulting from the application of strong chemicals or exfoliating ointments. Pain in the toes may result primarily from ischemia, even when there is an obviously deformed

nail, or a corn. It is strongly recommended that no local surgical or medical treatment of toes be instituted in any case until the arterial blood supply has been proved adequate by palpation of pulsations in the posterior tibial and dorsalis pedis arteries, and by the absence of abnormal color changes in the elevation dependence test. If arterial insufficiency is demonstrated, local treatment of painful toes should be extremely conservative, and all possible trauma should be avoided.

THE RÔLE OF SODIUM IN ADRENAL INSUFFICIENCY

ROBERT F. LOEB, MD
DANA W. ATCHLEY, MD

AND

JULES STAHL, MD

Rockefeller Foundation Fellow from the University of Strasbourg
NEW YORK

Thomas Addison¹ was the first to observe that complete destruction of the adrenal glands results in death. He also suggested that a study of the disease now known by his name might lead to some understanding of the function of these glands. This prophecy has been amply fulfilled. In addition to the clinical approach to the problem, as suggested by Addison, knowledge of the physiologic activities of these structures has been greatly enhanced by two other methods of attack. The first of these, a corollary of the clinical method, is represented by a study of the changes resulting from adrenalectomy in animals and the effects of extracts of various portions of the gland on the disturbances encountered. By the application of this technique, the elementary and fundamental fact that the extract of the cortex is essential for survival has been established. Furthermore, it has been shown that medullary extract as elaborated by the adrenal bodies is unnecessary for the normal activity of the animal. The second method, that of chemical isolation and synthesis, has already contributed enormously in defining many of the functions of the medullary secretion, epinephrine. The isolation of cevamic acid from the adrenal glands is another step that has been accomplished, but the significance of the storage of this substance is still uncertain.² The future of the chemical approach, as far as the isolation of the active principle cortin is considered, is at the moment distinctly bright, and the physiologic and pharmacologic harvest to be reaped fills one with hope.

The adrenal glands appear to be running a close second to the pituitary body, which Harvey Cushing has so appropriately termed the leader of the endocrine band.³ The effect of the adrenals on blood pressure and smooth muscle behavior, their intimate relation to pigment and carbohydrate metabolism, and their influence on certain phases of electrolyte physiology are now indisputable facts. Many other activities have been suggested, and the relation which these less clearly identified functions bear to those enumerated must be determined in the future. It is apparent from this brief summary that the subject of adrenal physiology has become vast in its scope and that the various methods

Read before the California Academy of Medicine Oct 13 1934.

of study are consequently so divergent that they can hardly be covered by any one group of investigators. It is our purpose in this paper to discuss only one particular phase of the activity of the adrenal cortex, namely, that related to its regulatory effects on electrolyte physiology and renal function.

At the Presbyterian Hospital in New York we have for a number of years been studying the behavior of electrolytes in their relation to disease. That the approach to the problem of adrenal insufficiency through the study of salt and water metabolism is a logical one may be indicated by the following brief historical sketch of this subject.

As long ago as 1831, Dr W B O'Shaughnessy⁴ of Newcastle-upon-Tyne made a profoundly significant series of observations on the chemical pathology of cholera. He found that the state of collapse, or what since has been termed "medical shock,"⁵ was associated with a decrease in the water content of the blood, a decrease in the neutral and alkaline salts of the blood, and an increase in its urea content. Moreover, he found that the inorganic constituents lost from the blood had been excreted through the intestinal canal. He concluded logically that the cure was "seemingly dependent upon the restoration of the water and salts to the blood stream." For this purpose, just 103 years ago, he resorted to the intravenous injection of physiologic solution of sodium chloride as a therapeutic measure, with the beneficial results now so familiar.

In 1874, Dr C Hilton Fagge⁶ of Guy's Hospital reported "a case of diabetic coma, treated with partial success by the injection of a saline solution into the blood." He introduced this measure because he recognized that the state of dehydration and collapse was essentially similar to that studied by O'Shaughnessy in cholera. The importance of the loss of inorganic base and water in the production of shock is now universally recognized, and for this reason no one today would care to rely on insulin alone in the treatment of severe diabetic acidosis.

Surgeons have for many years noted the salutary effect of the intravenous injection of physiologic solution of sodium chloride in the prevention and treatment of the state of shock resulting from pyloric and high intestinal obstruction, as well as from those conditions in which for some reason there exist fistulous openings from the upper gastro-intestinal tract or the bile ducts. Gamble was the first to show that the benefit derived from this therapeutic measure was due to the replacement of water and base lost from the body.

The state of shock that may develop in these diseases as well as in certain other pathologic conditions is primarily due to the continued loss of salt and water from the blood stream and the reservoirs existing in the intercellular spaces of the body. The mechanism involved in the loss of salt and water from the blood stream and intercellular spaces is obvious in cholera, as was demonstrated by O'Shaughnessy, and is also clear in the case of high intestinal obstruction. In diabetic acidosis, base and water are lost through the kidneys with the excretion of ketone bodies. We⁷ have shown recently that, even without ketosis, base as sodium and potassium is also lost through the kidneys coincident with the development of severe glycosuria. The reason for this is not yet clear.

The syndrome of salt loss, dehydration and the resultant state of shock, typical of these disturbances, is characterized clinically by progressive weakness and overwhelming prostration, nausea and vomiting, increasing pulse rate with falling blood pressure, subnormal temperature, sunken eyes and loss of the normal turgor of the subcutaneous tissues. Examination of the blood shows an increase in the hematocrit, i e., decrease in water content, decrease in the bicarbonate or chloride content of the serum or a decrease in both accompanying a fall in the sodium. When the development of this syndrome is rapid there is also an increase in urea, which appears before the final stages of oliguria or anuria develop.

The similarity of this syndrome to the picture of acute adrenal insufficiency in Addison's disease suggested the possibility that in this condition also the loss of salt and water might prove to be a significant factor.

E C, a Negro man, admitted to the Presbyterian Hospital in May 1932, presented the typical picture of acute adrenal insufficiency. A study of the blood serum showed that the sodium content was reduced from the normal of 140 milliequivalents per liter to 109.5 milliequivalents per liter, a change even greater than that usually found in those conditions in which shock has been known to follow the loss of salt and water from the body. Chloride and carbonate were reduced in concentration, whereas potassium, sulphate, phosphate and serum protein were increased. The nonprotein nitrogen was 75.9 mg per hundred cubic centimeters. The patient was treated with cortical extract prepared by Dr R. Zwemer but died two days later. At autopsy the adrenal glands were found to be replaced by large tuberculous masses.

J V, admitted to the hospital a week later, had equivocal mild Addison's disease. A chemical survey of the blood showed that the sodium concentration was slightly reduced, being 131 milliequivalents per liter. The blood chloride was also slightly decreased, but the other analyses were normal.

A third patient, M W, admitted to the hospital in July 1932, was suffering from unmistakable Addison's disease. She was prostrated, the blood pressure was 85 systolic, 55 diastolic, and she vomited from time to time. The sodium content of the blood was only 123.5 milliequivalents per liter, and there was an equivalent reduction of chloride and bicarbonate. Except for a blood sugar of 73 mg per hundred cubic centimeters, the other analyses were all normal. During the next week she went downhill rapidly with a diffuse bronchitis, and after seven days she was in a moribund condition, the blood pressure falling to 65 systolic, 48 diastolic. At this time the blood sodium had fallen to the amazing level of 107.8 milliequivalents per liter. The chloride and bicarbonate fell with the sodium, while the potassium, serum protein and nonprotein nitrogen increased.

On the basis of these observations it seemed probable that loss of salt and the resultant dehydration contributed to the state of shock, as in the other conditions that have been discussed.⁸ In view of this fact, the patient was given 15 Gm of sodium chloride by mouth and by rectum daily and received a single intravenous dose of 10 cc. of Eschatin, Parke, Davis & Co (adrenal cortical extract made according to the method of Swingle and Pfaffner). After a week, she had regained sufficient strength to sit up in a chair. The sodium content of the serum had risen to 133 milliequivalents per liter, and there was a corresponding rise in chloride and bicarbonate. The potassium, nonprotein nitrogen, serum protein and hematocrit fell, and the blood pressure rose to 85 systolic, 65 diastolic. The patient went home and continued to take between 7 and 15 Gm of salt daily in addition to her diet (chart 1). The patient remained quite well doing most of her housework and walking a mile or so a day and occasionally dancing. The blood sodium had risen to the normal value of 139.5 milliequivalents per liter, and the blood pressure was about 100 systolic, 75 diastolic.

Whether salt and water replacement or a single dose of Eschatin had been responsible for the improvement, which continued at home could not be finally settled until it could be ascertained whether salt withdrawal would induce adrenal insufficiency. The opportunity for our much desired observation finally presented itself. Slight puffiness about the eyes and mild edema of the ankles developed, and the patient was advised to follow a salt-poor regimen. One week later she was readmitted to the hospital with a history that after two days of salt withdrawal she became so weak that she had to

Chart 1—Relation of symptoms to blood sodium concentration in Addison's disease. Before the administration of sodium chloride: (1) patient weak, nauseated and vomiting; (2) patient in a moribund condition. After the administration of sodium chloride: (3) patient much improved walking about ward; (4) patient at home doing part of the housework.

go to bed. Weakness had been progressive and vomiting began on the third day of salt withdrawal. When she entered the hospital it was found that the blood sodium had again fallen to 126.8 milliequivalents per liter and the blood pressure was 86 systolic, 60 diastolic. At this time therapy consisted of the administration of salt alone, no cortical extract being used. Improvement was striking. Strength returned, blood pressure rose, vomiting ceased and after one week she was discharged, the blood sodium having risen to 138 milliequivalents per liter and the blood pressure to 122 systolic, 80 diastolic. At the present time, more than two years later, the patient is relatively well.⁹

On the basis of these observations we could

conclude (1) that the acute adrenal insufficiency of Addison's disease was associated with a sharp decrease in the sodium content of the blood and with dehydration, (2) that insufficiency had been induced in one patient by salt withdrawal and (3) that this state had been alleviated by salt administration.

The next step in this study was that concerned with the mechanism by which the sodium, the chloride and the bicarbonate concentrations of the blood were decreased in the acute adrenal insufficiency of Addison's disease. The question presented itself as to whether sodium was actually lost from the body with the development of adrenal insufficiency or whether its distribution within the body was merely altered. To answer this question, it was decided to resort to blood studies and electrolyte balance observations in the adrenalectomized dog. Marine and Baumann¹⁰ had shown in 1927 that the sodium content of the blood of adrenalectomized cats was decreased while that of potassium was increased. Zwemer had confirmed these observations, but the fate of the lost sodium had not been established.

In the dogs studied by us,¹¹ the sodium content of the blood fell rapidly following the removal of the second adrenal gland. This change was accompanied by a drop in the level of chloride and bicarbonate. The balance studies showed a striking increase in sodium excretion by the kidneys (chart 2). This urinary loss of sodium proved that the changes in blood sodium

concentration were due to actual sodium loss rather than to internal redistribution. Furthermore, the sodium excretion was sufficiently great to indicate that sodium must have been lost from interstitial fluid as well as from the blood stream. This might be expected from the equilibrium known to exist between blood serum and interstitial fluid. Not only was the total amount of sodium excreted by the kidneys increased after adrenalectomy, but also the concentration of this ion in the urine was definitely augmented in spite of the fact that the urinary volume was greater during the first four or five days after operation than in the control periods (chart 3). These results have since been confirmed by Harrop and his co-workers,¹² who have studied the effects of cortin withdrawal in adrenalectomized dogs.

The other changes observed in these animals can be summarized briefly. The chloride ion decreased in the blood after adrenalectomy, and chloride excretion was augmented. While the behavior of this ion approximately paralleled that of sodium, the changes were not correspondingly as great. The potassium content of the blood increased, although no consistent abnormality of potassium excretion could be determined by the balance studies. The increase in nonprotein nitrogen was marked following adrenalectomy as was first observed by Marshall and Davis,¹³ and it should be noted that this abnormality developed at a time when the urinary volume was greater than before adrenalectomy. In the light of these observations, it becomes apparent that nitrogen retention is not dependent on failure of urinary secretion as a result of hypotension. Furthermore, current explanations, which imply that this type of renal insufficiency results from a decrease in the water available for urinary excretion, are not valid.

Having established the fact that a decrease in sodium concentration in the blood occurs in Addison's disease and in adrenalectomized animals, and having shown in dogs, as Harrop¹⁴ has since confirmed in man, that adrenal insufficiency is associated with a marked loss of sodium through renal excretion, we were next faced with the problem of the mechanism of this disturbance. At the present time, unfortunately, we must resort to the realm of speculation for an explanation. Several possibilities present themselves. First, it is conceivable that the removal or destruction of the adrenal glands is associated with the liberation of some foreign acid that calls on fixed base for its excretion, as is the case in diabetic acidosis.

Chart 2—Sodium loss following adrenalectomy in dogs. The great loss of sodium that follows adrenalectomy takes place through the kidneys.

Ketone bodies usually play no part in adrenal insufficiency and Harrop¹² has shown that the lactic acid content of the blood is not increased in the dog suffering from hypo-adrenalism. Nevertheless, it is possible that some unrecognized organic acid might be present in amounts sufficiently great to produce the disturbances found.

Acidosis due to an organic acid should be associated with an increase in the excretion of urinary ammonia.

Chart 3—Relative increase in sodium excretion in relation to water excretion after adrenalectomy in the dog

Therefore the urinary ammonia excretion was studied in a patient with Addison's disease. As the patient drifted into marked insufficiency and while the blood sodium dropped from 135.3 milliequivalents per liter to 123.4 milliequivalents per liter, the ammonia excretion was normal and appeared to decrease slightly as insufficiency became acute. With the administration of salt and a simultaneous rise in the blood sodium to 138.1 milliequivalents per liter, the ammonia excretion increased slightly.¹⁵ This year we¹⁶ have followed the ammonia excretion in an adrenalectomized dog, kept alive with the aid of cortin and salt. When moderately severe adrenal insufficiency was allowed to develop in this animal there was certainly no increase in ammonia excretion and possibly a slight decrease. Thus it seems highly improbable that the loss of sodium is dependent on an acidosis due to an organic acid. Sulphate and phosphate ions may be retained in adrenal insufficiency but can hardly be held responsible for the loss of base.

As a second explanation, it might be assumed that the loss of sodium from the body is due to the loss of water through the kidneys. This hypothesis is untenable because, as has been mentioned, the loss of sodium is relatively much greater than that of water. Furthermore, with primary dehydration one would expect an increase rather than a decrease in the sodium content of the blood.

Perhaps the most attractive hypothesis which may be advanced at this time is that the adrenal cortex serves as a regulator of sodium metabolism. The locus of this action is uncertain, but the evidence at hand suggests that the adrenal cortical substance acts on the kidney to control the excretion not only of sodium but also of urea. In adrenal insufficiency the rate of salt excretion is increased while urea elimination is retarded. The concept that an internal secretion may control the metabolism of an inorganic ion is no longer unique. That the behavior of the phosphate and calcium ions is to a large extent regulated by the parathyroid secretion is established, and the influence of the thyroid gland on iodine metabolism is well recognized.

Before turning to the more practical aspects of the role of salt in Addison's disease, it may be of interest

to mention one phase of the experimental work carried on during recent months.¹⁶ We have made comparative studies of the effect of the withdrawal of salt and of cortin in an adrenalectomized dog. In both instances the sodium content of the blood falls and the urea concentration increases, as Harrop has also observed.¹² As might be anticipated, the changes are much more acute and more pronounced following the withdrawal of cortin, but the type of response is identical in the two instances (chart 4). When cortical extract is completely withdrawn, the sodium level cannot be maintained even with the administration of as much as 0.3 Gm. of salt per kilogram daily. This is a point that should be kept in mind in relation to the clinical course following the treatment of Addison's disease. Finally, it has been shown that salt may be completely withdrawn from the diet without inducing a fall in the blood sodium level or an increase in the urea content of the blood, provided a cortical extract of adequate potency is employed. Under these conditions the dog is in all respects as normal in his physiologic responses as is the animal with intact adrenal glands.

Of greatest interest to the clinician is the applicability of laboratory investigation to the diagnosis and treatment of disease. Most important is a critical analysis of the accuracy and limitations of the methods so employed. The first question that naturally comes to mind is concerned with the frequency with which the concentration of sodium in the blood serum is decreased. We have had the opportunity of making sodium determinations on the blood of sixteen patients with outspoken Addison's disease and in all but three the values were found to be definitely below normal.

These three patients were being treated with salt at the time, and in two of them a salt-poor regimen instituted later, brought about a sharp drop in the blood sodium level. Thus, in our experience it may be stated that the decrease in sodium content of the blood in

patients presenting themselves for treatment is a relatively constant finding, although the magnitude of the deviation from normal may be only slight in certain cases. Indeed, when the degree of damage to the adrenal cortex is relatively slight, it seems unlikely that any gross abnormality in sodium metabolism would be encountered. This view receives support from the fact that the removal of one adrenal gland is not attended by any significant physiologic disturbances. It must be emphasized that the decrease in the sodium content of the blood is not *prima facie* evidence of Addison's disease.

Base loss forms a characteristic part of the clinical picture in a number of the pathologic states already discussed, as well as in certain others, and a low sodium level has also been found in a few critically ill patients without structural changes in the adrenal glands. Thus it is clear that the sodium concentration

Chart 4—Comparison of the effect of the withdrawal of sodium chloride and of cortin on the blood sodium and blood urea level in the adrenalectomized dog maintained on a constant diet

of the blood in spite of its diagnostic importance, is not an infallible criterion of the presence of Addison's disease.

The effect of salt withdrawal in one patient has been mentioned, and it has been pointed out that the same experiment carried out under the proper conditions in the dog is associated with a fall in the sodium content of the blood. We have used this reaction as a diagnostic test in six patients suffering from Addison's

Chart 5—Comparison of the effect of salt withdrawal on the blood sodium level in patients suffering from Addison's disease and certain other miscellaneous pathologic conditions.

disease with quite consistent and at times alarming results (chart 5). The blood sodium level has fallen precipitously, as contrasted with that of patients suffering from other diseases, regardless of the initial values. Symptoms of profound weakness, prostration, nausea and vomiting, usually associated with a fall in blood pressure, develop in the course of from one to five days, and we are in complete sympathy with Harrop, who has warned against the dangers encountered with this procedure.

In one of our patients, E B, the chain of events accompanying salt withdrawal, was sufficiently unusual to merit comment (chart 5). This patient had suffered from the classic signs and symptoms of Addison's disease for eight months. Weakness and anorexia had progressed rapidly in the two weeks preceding admission. The initial blood sodium level was 132.6 milliequivalents per liter and the blood pressure was 82 systolic, 60 diastolic. When given a salt-poor diet, she became slightly weaker and drowsier for four days and ate but little. At the end of the fifth day, her condition became suddenly critical. She could hardly move because of weakness, she was semicomatose, her pulse was almost imperceptible, and the blood pressure fell to 58 systolic, 50 diastolic. Curiously enough the blood sodium had fallen to only 129.4 milliequivalents per liter, but the blood sugar concentration was as low as 48 mg per hundred cubic centimeters, and a moderate ketosis had developed. She was given 25 cc. of cortical extract intravenously and frequent injections of epinephrine, and a continuous infusion of salt solution and dextrose was started. The next day her condition showed little change. The blood pressure was 62 systolic, 40 diastolic and the state of shock persisted. The blood sugar rose and remained at a normal level, the ketosis disappeared but the blood sodium, despite salt and cortin therapy, fell to 124 milliequivalents per liter. The continuous infusions were kept up for seven days, and her general health improved greatly. At the present time she is eating satisfactorily, vomiting has stopped and strength has returned to some extent. She is taking 10 Gm of salt daily in addition to her diet.

This case has been presented in detail because it demonstrates that the picture of acute adrenal insufficiency is a complex one and that, while the loss of sodium with its attendant dehydration is of apparently great significance, other factors may prove to be of vital importance in a given case. In this particular patient, shock developed with a fall of only 3 milliequivalents in sodium, a change not significant in itself, although the eventual deviation from normal was about 16 milliequivalents per liter. In spite of the administration of large amounts of cortin, fluid and salt, the state of shock was not altered in twenty-four hours and the blood sodium fell sharply. The factor of hypoglycemic shock was superimposed on the other disorders. This phase of adrenal insufficiency, which Britton¹⁷ has stressed in his study of cats, is not, as a rule, striking in the dog and in the human being and may not be dependent on cortical insufficiency. Prompt alleviation of the hypoglycemia in this patient appeared to have little influence on the state of medical shock. Finally, ketosis entered into the complex picture and probably added to the state of dehydration. It is unfortunate that a diagnostic procedure so highly specific as is salt withdrawal in Addison's disease should be attended by such grave consequences to the patient.

A detailed discussion of the treatment of Addison's disease lies beyond the scope of this paper, but it is appropriate that reference should be made to the role of salt and cortin. The concept that salt solution is of value in the treatment of adrenal insufficiency in animals and man is not new. In 1898 Soddu¹⁸ first mentioned the fact that salt solution prolonged the survival of adrenalectomized animals, and this was confirmed by Banting and Gairns¹⁹ in 1926. Marine and Baumann²⁰ in 1927 administered salt solution to cats because of the decreased content of sodium in the blood and obtained the same result. Many other investigators have more recently arrived at the same conclusion. In 1932 Rogoff²⁰ wrote that the intravenous administration of physiologic solution of sodium chloride "becomes an indispensable adjuvant in the treatment of Addison's disease with extracts representing the hormone of the adrenal cortex." The explanation offered by Rogoff was fallacious in that the salt solution was administered to correct an assumed "intoxication." It seems more rational on the basis of present knowledge to assume that the salutary effects may be ascribed to a replacement of salt and water, which are lost concomitantly with the development of acute adrenal insufficiency.

The most convincing evidence for the value of salt as a therapeutic measure in adrenal disease in man, as well as in the adrenalectomized animal, is found in the fact that the withdrawal of salt may induce acute adrenal insufficiency and that frequently the only therapeutic measure necessary to relieve it is the readministration of sodium chloride. Nevertheless, it should be recalled that salt alone will not maintain the normal sodium level in the blood or cause indefinite survival of the completely adrenalectomized animal. In other words, a certain amount of cortical substance, either formed within the body or introduced from without, is essential to life. With this in mind it becomes obvious that salt will not relieve those individuals whose adrenal glands have been completely destroyed by disease.

Since the introduction of salt as a means of replacement therapy in our first case in 1932, we have treated and followed eight patients. The results have in reality been less confusing than might be judged from chart 6. Of the patients treated, two have died.

One of these, N, succumbed to a severe acute febrile illness with fever maintained at 105 F for one week. She had active pulmonary tuberculosis and at autopsy the adrenal glands were found to be completely replaced by tuberculous tissue.

Patient C had been in another hospital for adrenal insufficiency, where he had been treated with salt for some months. He had tuberculosis of the right kidney and of both lungs. While under our observation he remained quite well from the adrenal standpoint and the blood sodium was maintained at a level of 135 milliequivalents per liter. His condition was so satisfactory that nephrectomy was contemplated. He was admitted to the wards for cystoscopy to determine the status of the other kidney. Following this manipulation, the temperature rose abruptly and never returned to normal. He was treated with salt and on one occasion with cortin, but he grew progressively weaker; the blood sodium continued to fall to a final level of 114 milliequivalents per liter after four months, at which time he died. At autopsy he had diffuse miliary tuberculosis and primary atrophy of the adrenal glands, only scattered cells being found after careful microscopic examination.

Patient O has apparently active tuberculosis of the adrenal bodies. Salt withdrawal in this patient caused serious acute insufficiency associated with a sharp fall in the blood sodium content in thirty-six hours. Salt administration relieved the clinical symptoms, but it has not been possible to raise the sodium to a normal level in spite of the ingestion of 20 Gm daily. During a period of increased fever, the sodium fell still further. In recent weeks, however, improvement in the sodium content of the blood has been encouraging and has accompanied a fall in the temperature.

It is of interest that any febrile episode in patients suffering from Addison's disease appears to decrease the function of the remaining adrenal tissue much as infection increases the severity of diabetes mellitus.

The remaining five patients are all taking between 7 and 10 Gm of salt a day in addition to that of the diet. Their blood sodium levels remain within normal limits, and they are able to lead very much more active lives than before salt therapy was instituted. They will suffer from easy fatigability, they have occasional nausea, they feel the cold intensely, and pigmentation is little if at all changed. Our experience has shown that the optimum therapeutic dose of salt is variable and can be determined only by the method of trial and error. The clinical improvement of patients following the administration of salt has been confirmed by Harrop¹⁴ and Snell²¹ and a number of other investigators in recent months.

The successful treatment of Addison's disease will be accomplished only when the active principle or principles of the adrenal cortex become available for clinical use in high concentration and in a form that lies within the economic limits of sufferers from this disorder. At the present time numerous reports of treatment with cortical substance continue to enter the literature. Patients are said to "feel better" with this treatment and the blood pressure appears to rise, yet death from Addison's disease seems to be the ultimate outcome.

Although we have used a commercial preparation of cortical substance only occasionally, we have seen little objective evidence of beneficial effect. For example, one of our patients who had been maintained in the hospital on a regimen high in salt remained weak, and the blood sodium was fixed at a level of about 125 milliequivalents per liter over a period of many weeks. He was therefore given 4 cc of a commercial preparation of cortical extract intramuscularly daily for four days and then 10 cc daily for two days, without any effect on the blood sodium level. The fall in sodium in a patient who received 25 cc of cortical extract in one day has been mentioned. Other examples might be cited. Perhaps our results may be best summarized as follows:

SUMMARY

If adrenal insufficiency in man is not relieved by salt administration, it will not be relieved by commercial cortical extracts given in the usual dosage. It is distinctly hopeful, however, for the future of this type of therapy that the commercial extract is entirely adequate for the healthy survival of the adrenalectomized dog.

The studies that we have presented indicate that there is a definite relationship between sodium metabolism and the active principle of the adrenal cortex. When cortical insufficiency develops, the disturbances in sodium metabolism manifest themselves in a number of ways that have significant diagnostic and therapeutic implications. The sodium concentration of the blood is decreased because of an increased rate of sodium excretion. The diagnostic change in the sodium level becomes more apparent and specific when salt is withdrawn from the diet. The withdrawal of salt, however, may result in an adrenal crisis dangerous to the patient. Conversely, the administration of salt will frequently alleviate acute adrenal insufficiency, and the continuation of this therapy mitigates to a considerable extent the signs and symptoms of Addison's disease. Finally, it should be recalled that, when destruction of the adrenal glands is complete, salt alone will not maintain life.

CONCLUSIONS

It should be emphasized once more that no attempt has been made to consider adrenal physiology in its entirety. There are many important and fascinating aspects of the problem, of which the work discussed constitutes but one.

620 West One Hundred and Sixty-Eighth Street.

Mongolism.—All the known facts concerning mongolism seem to point to some condition in the ovary as underlying its pathogenesis. We have a sufficient amount of circumstantial evidence to borrow a legal term, to justify the speculation that foci of tissue change—perhaps scars—marking the sites of old ovulation are the cause of the trouble. Rosenoff, A. J. and Handy, Leva M. *Etiology of Mongolism, with Especial Reference to Its Occurrence in Twins*, *Am J Dis Child* 48:764 (Oct.) 1934.

MENTAL CHANGES ASSOCIATED WITH PERNICIOUS ANEMIA

C. W. OSGOOD, M.D.
WAUWATOSA, WIS.

While in the literature there have been many accounts of involvement of the central nervous system in pernicious anemia, most of these have described only the cord changes. A few¹ have also mentioned cerebral symptoms and there have been a fair number of reports concerned primarily with the mental changes. Mild mental changes with irritability as an outstanding feature are reported in as high as 40 per cent of cases, but frank psychoses are said to be rare, occurring in not more than 4 per cent.² The majority of writers assume the existence of a direct etiologic relationship between pernicious anemia and the associated psychosis, although a number stress the importance of heredity and psychogenic factors as well. Hackfield,³ on the other hand, takes the view that there is no such fundamental etiologic relationship, and Musser and Wintrobe⁴ say "It is usually considered that major psychoses are predisposed to rather than a part of the disease pernicious anemia."

As long ago as 1905 the presence of psychoses in pernicious anemia was described by Langdon,⁵ but, as Hackfield³ says, previous to the introduction of liver therapy all the patients died and the only method of showing the relationship of the pernicious anemia to the psychosis was necropsy. The pathologic studies were not conclusive. Since the use of liver the effect of treatment on the psychosis has been observed but

the reports have been diverse. Arguments against pernicious anemia being the primary cause of an associated psychosis are the following:

- 1 There is very often a family history or personal past history of mental disease.
- 2 The psychoses present no characteristics that clearly distinguish them from endogenous depressions or other well recognized mental disorders.

3 Mental improvement, when present, does not parallel the physical.

4 Autopsy shows no consistent relation between the pathologic changes in the brain and the psychosis.

Aside from mere association, the chief argument for the pernicious anemia having a causal relationship to the psychosis is the frequent occurrence of an "anxious-paranoid" picture, which, as Francke⁶ says, "has been too often described in association with pernicious anemia to be a coincidence." The proponents of the theory that pernicious anemia is an important factor in the production of the associated psychosis admit that there is often no mental improvement under liver treatment but attribute this, as in the case of persistent cord symptoms, to the existence of irreversible pathologic changes.

From the records of the Milwaukee Sanitarium I have gathered seven cases of pernicious anemia with associated mental changes. Through the courtesy of physicians at the Milwaukee County Hospital for Mental Diseases and the Milwaukee County Asylum for the Chronic Insane, I have examined records of ten additional cases. Through a personal communication and a search of the literature I have reports of fifty-nine other cases, thus making a total of seventy-six cases for analysis (table 1). In some of these the data are rather meager. In fifty-two cases both family history and past history are given, and there is in this group a personal or family history of mental disease in twenty-four. There is a family history of mental disease in nineteen of fifty-two, and a personal history of previous mental disease in six of fifty-five cases in which data are given. In thirty-four cases, fairly definite conclusions are possible as to the correlation between the blood picture and the mental state. In eight there appears to be a correlation and in twenty-six there does not.

When one comes to consider the effect of liver treatment on the psychoses, the material for analysis is more restricted. Quite a number of the collected cases antedate the era of liver therapy, a few show an obviously incidental relationship in that a chronic psychosis of the schizophrenic type existed for years before the development of pernicious anemia, a few show only mild mental symptoms and a few are classed as terminal psychoses. This leaves a group of thirty-six treated cases for more detailed analysis. Of the thirty-six patients, ten died. Three of the deaths were due to causes other than the anemia—pneumonia in two, and coronary disease in the third. The other seven patients failed to respond physically to liver treatment. Thr-

Institution A Milwaukee Sanitarium Institution B Milwaukee County Hospital for Mental Diseases Institution C Milwaukee County Asylum for the Chronic Insane

teen patients of the surviving twenty six had not improved mentally at the time the reports were made, although all but one had shown a good physical response. Three of these thirteen cases were complicated by arteriosclerosis. Four were considered to be dementia praecox. Another patient did not show a good physical response to liver and after being normal mentally for two years lapsed again into a depressed state. Another case had been observed for only one month at the last report. Of the remaining four cases that failed to show permanent mental improvement, two had shown a temporary change for the better. Thirteen patients recovered physically and mentally under liver treatment, but in these the duration of the psychosis showed a wide range from a minimum of two months up to twenty six months, and in only six of the thirteen did the mental improvement approximately parallel the improvement in the blood picture (table 2).

Essential data of seventeen cases in Milwaukee are presented in table 3, and one case is here reported in detail.

REPORT OF CASE

W L, a white woman, aged 43, married, had no history of previous mental illness. Her health had been good until an attack of influenza one year previously. Since then she had tired easily. No blood count was made before admission.

For two months the patient had been nervous. She worried, was easily upset and was "blue." Two weeks before admission she became ill with influenza and had pain in the right lower quadrant of the abdomen. A diagnosis of appendicitis was made but operation was not performed because of the influenza. The pain subsided in three or four days. Five days after the onset of the acute illness the patient showed some confusion and on the next day kept her eyes closed and would not talk. Following this she talked continually and cried a great deal. She was too distractible to eat so had to be fed, and she could not sleep without hypodermics. She thought God talked to her. Until the day of admission she was in bed, but then was brought to us by automobile from her home in northern Michigan.

The social history was irrelevant.

There was no family history of nervous or mental disease or other hereditary illness.

Physical examination showed the patient to be well developed and well nourished but very pale. The tongue was rather smooth, especially at the tip. A soft blowing systolic murmur was heard at the base of the heart. The spleen was not palpated. Slight edema of the ankles was noted. The deep reflexes were normal and there was no Babinski reflex. A morbilliform rash was present over the abdomen, in the axillary fossae and faintly on the back.

The patient remained in bed but talked almost constantly in a low tone. Rarely she was more excited, jumped out of bed, ran into the hall, and even showed violence toward her nurse. Most of the time she was pleasant and cooperative but by spells was irritable and antagonistic. Her talk was incoherent and rambling. She appeared disoriented in all spheres and confused.

Laboratory examination showed hemoglobin, 58 per cent, red blood cells, 2,600,000, white blood cells 3,000 color index, 1+, marked anisocytosis and poikilocytosis, polymorphonuclear leukocytes, 69 per cent, lymphocytes 27 per cent, monocytes, 2 per cent, eosinophils, 2 per cent, no free hydrochloric acid in the stomach contents, Wassermann reaction, negative, no abnormality of the urine

There was a low fever on admission but this gradually subsided. The skin rash cleared entirely in a few days.

A diagnosis of pernicious anemia was made and liver therapy instituted. Steady gradual improvement of the blood picture followed and the patient's color and strength improved.

During the first month, confusion continued to be an outstanding feature of the mental picture. People about her were misidentified and at times she had delusions that the food was poisoned, that there was dirt in her bed and that the bed blankets were charged with electricity. She stopped eating toward the end of the fourth week but after two or three forced feedings began again to eat and from that time on made steady progress both physically and mentally. During her convalescence she was quiet, inactive and mildly depressed but gradually returned toward normal, so that two months after admission she was discharged as cured.

From this study one finds little unequivocal evidence to support the assumption that pernicious anemia can cause psychoses or that mental changes may be a manifestation of pernicious anemia in the same sense as may neurologic changes. Few patients with pernicious anemia develop psychoses and of those who do almost half have a predisposition to mental illness as indicated by the family or past history. While a few of the cases, such as the one reported here in detail presenting the severe anemia and relatively prompt physical and mental recovery, might lead one to think that there is a close correlation between the physical and mental changes, the evidence is far from being conclusive. Failure of the mental symptoms to improve might be due in some instances to complications such as arteriosclerosis and in others may be explained on the theory of irreversible pathologic changes, but one would expect those cases in which the psychosis did clear to show a closer correlation between the physical and the mental improvement. In the recovered cases which I have cited, the duration of the psychosis in one case was two months and in one three months, but in the others the mental symptoms lasted four, five, six, ten, twelve and even twenty-four and twenty-six months. True, the mental symptoms might be slower to respond to treatment than the blood picture, but one would expect a more consistent mental response than I have been able to find.

The majority of the reported psychoses associated with pernicious anemia are of the anxious-paranoid type, but this does not necessarily indicate an etiologic relationship. In the first place the preponderance of acute over chronic types of psychoses may be only apparent, since the association of pernicious anemia with chronic psychoses would probably be presumed to be incidental and would not lead to the reporting of such cases. Secondly, the preponderance of depressive and paranoid manifestations in the reported cases may be explained, as has been suggested by several writers, on the ground that the physical symptoms of pernicious anemia, the weakness, paresthesias, incoordination, and so on, would serve to color the mood or form the basis for paranoid ideas. Manic psychoses in association with pernicious anemia are notably rare; only four of the seventy-six cases.

I conclude from this study that the association of psychoses with pernicious anemia is probably largely incidental.

EFFECT OF ANTERIOR PITUITARY-LIKE PRINCIPLE FROM THE URINE OF PREGNANCY

ON UNDESCENDED TESTES IN MAN

BRUCE WEBSTER, M.D.

NEW YORK

During the last two years, several accounts of the treatment of cryptorchidism in man by pregnancy urine extracts have appeared in the medical literature. Schapiro¹ reported a group of cases in which the injection of anterior pituitary-like substance caused increased mobility of the testes. The details of treatment and the position of the testes were not given. Goldman and Stern² described two cases of unilateral undescended testis treated with commercial extract of pregnancy urine. In one case the testis descended into the scrotum but in the other it remained in the inguinal canal. These patients were also given thyroid substance and dried pituitary substance by mouth. Sexton³ described six cases of so-called hypogenital condition treated with pregnancy urine extracts. In four of these, descent of a cryptorchid testis occurred during treatment. Rubinstein⁴ described one case of bilateral cryptorchidism successfully treated in the same manner. Aberle and Jenkins⁵ have carefully treated five cases. In only two of them did descent of the cryptorchid testis occur. The number of units of the pregnancy urine extracts used varied widely in each of these series. Aberle and Jenkins have analyzed their results and suggested that the failure of treatment may have been due to insufficient dosage, to the nutritional state of the child or to a mechanical block in the inguinal canal.

In spite of the apparently clearly defined cases in which descent of a cryptorchid testis occurred during the administration of pregnancy urine extracts, much skepticism has been expressed by physicians as to the efficacy of this form of therapy. Accordingly, the following additional series is presented in the hope of establishing further the rationale of the procedure and providing additional data as to dosage.

EXPERIMENTAL

Since July 1933, eleven cases of cryptorchidism have been treated by the injection of pregnancy urine extracts. These cases have not been selected and comprise all the available individuals with cryptorchidism. The position of the testes was checked by at least two different observers before treatment was begun. Attempts were made to measure the length and width of the testes, but these were later abandoned because of the inconsistency of the method. The pregnancy urine extract used was the commercially available "Follutein."⁶ The injections were given by having the patients come into the clinic daily or they were administered by the family physician who referred the case. In each instance the initial dose was 25 rat units. This

This investigation was supported by the Barbara Henry Research Fund.

was increased by 25 rat units daily until a 250 rat unit dosage was reached. This amount was then given daily for two weeks.

In the case of all boys over 11 years of age, an assay of the urine for "male" hormone was made prior to the beginning of the treatment and again approximately two weeks after the completion of the injections. Extraction of this hormone was done by the Womach and Koch method. Assay was carried out on white leghorn capons. The combs were photographed daily under standard conditions and the area of the comb shadow was measured by a planimeter.⁶

The following case summaries give the condition of the patients before treatment and the details of the therapy.

CASE 1—B C, aged 6 years, weighing 17.7 Kg, was a normal looking boy with good general nutrition. The right testis could not be felt in either the inguinal canal or the scrotum. The left testis was normal. The penis was normal except for phimosis.

Injections of pregnancy urine extracts were begun on September 14. On September 29, after 2,000 units had been given, the right testis descended into the scrotum. On the previous day the child's father, who was a physician, had been unable to feel this testis either in the inguinal canal or in the scrotum. On September 30, the right testis was smaller than the left and very soft. Three weeks later, October 20, this testis was of the same size and consistency as the left one, although no further injections of pregnancy urine extract had taken place since September 30.

CASE 2—C T, aged 6½ years, weighing 18 Kg, had a normal general physique but was slightly underweight. The right testis was in the upper third of the inguinal canal. The left testis was in the scrotum in normal position. The penis was normal.

After the injection of 2,300 units of pregnancy urine extract over a three weeks period, the right testis descended into the normal position in the scrotum. Two weeks later it had increased in size until it was only slightly smaller than the left. Sensation was present and the testis was of a firm consistency.

CASE 3—F F, aged 9 years, weighing 37.7 Kg, had been overweight since the age of 6 and had always been considered healthy. When the child was 8 years of age his parents noted that he had a small penis and that both testes were absent from the scrotum. When he was 8½ years old, 300 rat units of "Antutrin S" per week were administered for two weeks with no apparent effect. On physical examination the child was found to be overweight. Neither testis could be felt, either in the inguinal canal or in the scrotum. The penis was infantile.

March 6, 1934, pregnancy urine extract injections were begun. March 29, after 3,600 rat units had been given, the right testis was in the scrotum and the left testis could be felt in the upper portion of the inguinal canal. April 12, after another 3,000 rat units of pregnancy urine extract had been given, the left testis was noted to lie high in the scrotum, while the right continued in the normal position. Therapy was discontinued. September 12, both testes were still in the scrotum and exhibited a firm consistency.

CASE 4—P E, aged 10 years, weighing 55 Kg, had poliomyelitis as a child. He had been overweight since the age of 7. Physical examination showed overweight. The penis was normal. The right testis was at the lower end of the inguinal canal and could be forced into the scrotum. The left was not felt, either in the scrotum or in the inguinal canal.

Injections of pregnancy urine extract were begun on June 7, 1934. July 1, after 3,700 rat units, both testes were in the scrotum. They were firm but still below normal size. Bilateral hernias were present, through which the testes could be pushed to their original position in the canal. Operative repair of these is being arranged.

CASE 5—F C, aged 11 years, weighing 38.2 Kg was of normal general physique. The left testis was in the normal position in the scrotum. The right testis was not felt either in the inguinal canal or in the scrotum. The penis was normal.

After 2,400 rat units of pregnancy urine extract, given over a two weeks period, the right testis was found to be in the scrotum in normal position. It was approximately half the size of the left one. Ten days later, after daily injection of the extract, the right testis had increased in size until it was only slightly smaller than the left one.

CASE 6—H D, aged 11 years, weighing 44.2 Kg, was mentally defective. He had had no serious illnesses. He was a "fat baby" and had always been overweight. The right testis was in the normal position. The left one could not be felt either in the scrotum or in the inguinal canal. The penis was normal.

Injections of pregnancy urine extract were begun, February 5. February 20, after 1,900 rat units, the left testis was found to be in the scrotum. At that time it was less than half the size of the right testis. Injections were continued until April 26. At this time no difference in size or consistency of the two testes could be noted.

CASE 7—A H, aged 14 years, weighing 42 Kg, was normal looking and had had no serious illnesses. His general nutrition was good. The right testis was at the upper end of the inguinal canal. It could not be moved along the canal or expressed into the scrotum. The left testis was normal. The penis was normal and there was some growth of pubic hair.

After the administration of 4,000 rat units of pregnancy urine extract over a period of four weeks, the right testis was found to be in the normal position in the scrotum. It could, however, be pushed back through a hernial opening into its original position in the canal. The patient stated that it did not retract of its own accord. Arrangements are being made for operative repair of this hernia.

CASE 8—B B, aged 14 years, weighing 49 Kg, was of normal general appearance. The right testis was in the middle portion of the inguinal canal. The left was in the upper third of the inguinal canal. Both testes could be moved slightly but neither could be expressed into the scrotum. "Testicular sensation" was present in both. The penis was smaller than normal.

Injections of pregnancy urine extracts were begun on September 14. October 16, after 4,200 rat units had been given, both testes were in the scrotum in the normal position. They were smaller than normal but moderately firm.

CASE 9—G L, aged 15 years, weighing 64 Kg, had been followed in the clinic for several years. He had a chronic rheumatic endocarditis with mitral stenosis and insufficiency. In February 1933 a consulting urologist advised removal of an atrophic right testis, which could be felt in the upper end of the inguinal canal. The left testis was normal. The penis was normal.

Dec 18, 1933, injections of pregnancy urine extract were begun. December 30, after 1,500 rat units had been given, he noted that the right testis was high in the scrotum. Injections were stopped. This testis, which at the time of its descent was soft and small, increased in size steadily. In June 1934 it was of the same size and consistency as the normal left one.

CASE 10—M L, aged 21, weighing 65 Kg, was a tall boy of the so-called hypogentil type. The right testis was in the scrotum but was small and soft. The left testis could be felt in the upper portion of the inguinal canal. The penis was small. The prostate was small and soft.

Pregnancy urine extract was begun, June 2. July 10, after 5,000 rat units, the left testis was found to be in the scrotum. There was slight increase in size in the right one and this testis was definitely firmer. Daily injections of the extract were continued until September 6, at which time both testes were firm but still below the normal size. There had been an apparent increase in the size of the prostate.

CASE 11—W S, aged 26 years, weighing 65 Kg, had an operation at the age of 11 for bilateral cryptorchidism. The right testis was placed in the scrotum. The left testis could not be found. General physical examination was normal except for a left inguinal scar and the absence of the left testis in the scrotum.

⁷ Womach E B and Koch, F C. Proc. Sec. Internat. Cong. for Sex Research, p. 329.

⁸ These assays were aided in part by a grant from the Council on Therapeutics of the American Medical Association.

The patient was given 4,000 rat units of pregnancy urine extract over a period of one month. The left testis did not descend and no effect of the therapy was noted.

COMMENT

Of eleven cases of undescended testes which had been treated with pregnancy urine extract, the testes descended into the scrotum in ten instances during treatment. The one case in which failure occurred was a man of 26 who had had a previous exploration of the inguinal canal in an effort to locate the testis. Three of the cases were of bilateral undescended testes. In all these, both testes descended into the scrotum. In two instances, hernias persisted three months after the descent of the testes. Through these hernias the testes could be pushed back into the inguinal canal. Operative repair of the hernias will probably be necessary. In each instance the testes tended to increase in size after their descent into the scrotum. In three cases the recently descended testis could not on physical examination be differentiated from the normal one, three

TABLE 1—Summary of Cases

Case	Age Yrs	General Appearance	Condition of Testis Before Treatment	Treatment Pregnancy Urine Extract Rat Units	Result
1	5	Normal	Right testis not felt left normal	2 000	Descent of right testis into scrotum
2	6½	Underweight	Right testis upper third inguinal canal left normal	2 300	Descent of right testis into scrotum
3	9	Overweight penis small	Right testis not felt left testis not felt	3 600 + 3 900	Right descended into scrotum left descended into position high in scrotum
4	10	Overweight	Right testis in lower end of inguinal canal left not felt	3 700	Right descended into scrotum left descended into scrotum
5	11	Normal	Right testis not felt left normal	2 400	Descent of right testis into scrotum
6	11	Overweight	Right testis normal left not felt	1 000	Descent of left testis into scrotum
7	14	Normal	Right testis upper end of inguinal canal left normal	4 000	Descent of right testis
8	14	Normal	Right testis middle portion inguinal canal left upper third inguinal canal	4 200	Descent of both testes into scrotum
9	15	Chronic rheumatic endocarditis overweight	Right testis upper end inguinal canal left normal	1 500	Descent of right testis into upper portico of scrotum
10	21	Hypogenital type	Right testis in scrotum small left upper portico inguinal canal	5 000	Descent of left testis into scrotum
11	26	Normal	Right testis brought to scrotum at age of 11 by operation left testis not found at operation	4 000	No effect noted

months after the cessation of treatment. The others remained smaller than normal. More striking than this increase in size was the change in consistency. All of them increased in degree of firmness.

Assays of the urine for "male hormone" of the five boys who were above the age of 11 years showed no definite change after therapy (table 2). This was to be expected, since all these patients except one had normal secondary sexual characteristics and in this one instance (case 10) the departure from normal was not extreme.

The dosage of the pregnancy urine extract used was greater in our cases than in most of the others pre-

viously reported. Beyond slight erythema at the site of injection, no reactions were encountered. With our system of dosage, descent of the testis usually occurred during the third week of treatment. It would appear that the time period over which the hormone is administered, as well as the total number of units given, is a factor.

Our results in the treatment of undescended testes with pregnancy urine extracts show a smaller per-

TABLE 2—Assay of Urine for "Male" Hormone

Case	Age	Male Hormone Before Administration of Pregnancy Urine Extract (Average Cock Units per 24 Hours)	Result	Male Hormone after Administration of Pregnancy Urine Extract for 1 Month (Average Cock Units per 24 Hours)
11	26	3 0	None	2.3
10	21	2 0	Left testis descended into scrotum	2.4
9	15	1 0	Right testis descended into scrotum	1.3
8	14	1 6	Descent of both testes into scrotum	2 0
7	14	2 0	Descent of right testis into scrotum	1.3

centage of failures than most of the reported cases. Although our cases were unselected, it is probable that there was an element of chance in determining the high percentage of cases in which descent occurred, since it is scarcely conceivable that in a certain group of cases the testes are not prevented from descending by a mechanical block such as the adhesions commonly found at operation. However, the incidence of successful descent was great enough to make it appear that this method of therapy should be tried before operative procedure is considered. Further, it would seem advisable to institute therapy at as early an age as possible, in order to prevent destruction of the spermatogenic function of the testis. Although spontaneous descent may occur up to the age of puberty, it does not appear desirable to wait until this time before starting therapy, since the testis may have already undergone considerable damage. The relatively large doses of pregnancy urine extracts and the time period over which they were given may have been important factors in bringing about the result.

No conclusions could be reached in our cases in regard to the mechanism that was responsible for the descent of these testes. In two of the cases, hernias persisted and the testes could be expressed back into the inguinal canal, although they did not tend to assume this position spontaneously. The increase in size of the testis, which occurred in most instances after descent, may be an important factor in preventing its return to the abdominal cavity. Schloss⁹ has suggested that the presence of "anterior pituitary-like" substances in the blood of the mother is responsible for the descent of the testes in man during fetal life. It would seem that the same mechanism, whatever it may be, can be instigated by substitution therapy in the child, and that its success depends on the absence of any mechanical block.

SUMMARY

Eleven cases of undescended testes in man were treated with a commercial extract of pregnancy urine.

⁹ Schloss O. M. Interpretation of Some Recent Advances in Medicine in Terms of Equilibrium. *Am J Dis Child* 46: 1 (July) 1933.

Three of these patients had bilateral undescended testes. In ten of the cases, descent of the cryptorchid testes occurred during the period of treatment. No increase in the excretion of "male" hormone was noted after descent of the testes.

BREATH ODORS FROM ALLIACEOUS SUBSTANCES

CAUSE AND REMEDY

HOWARD W. HAGGARD, M.D.

AND

LEON A. GREENBERG, Ph.D.

NEW HAVEN, CONN.

Offensive odor of the breath is often a matter of considerable importance to those afflicted, and medical advice is occasionally sought. The fact that the odor may arise from pathologic conditions in the structures of the mouth and respiratory tract is well recognized. But in many cases no definite pathologic changes are found. Moreover, the odor may not be present continuously but only during temporary periods of disturbed health or during menstruation.

It has been suggested that in such cases the substances causing the odor are of systemic origin, that the air in the lungs is tainted by aeration from the blood, or in the mouth from secretion of the substances into the saliva, or, again, that the odor arises directly from the stomach. It is more probable, however, as the evidence to be here presented also indicates, that generally the source of the odor is not systemic but local in the mouth or respiratory tract. Determination of the source is essential to any therapy.

As a phase of the problem that is directly amenable to experimental study, we have investigated the source of the odor arising after eating onion or garlic.

It is well known that there exists among different individuals wide differences in the intensity and particularly in the persistence of the odor on the breath after eating onion or garlic. Usually the breath loses its odor within a few hours, but in occasional individuals even small amounts of onion or garlic inadvertently eaten in salads, soups or sauces taint the breath for several days. Moreover, in such cases the odor often loses its typical alliaceous character after some hours have passed and, although the breath is offensive, it is difficult to identify precisely the nature of the odor. As a rule in the past little relief could be given for this condition except by disguising the odor with the use of mouth washes containing aromatic oils.

The odor from onion and garlic is due to the essential oils contained in these vegetables. That of onion is mainly allyl-propyl disulphide, $C_6H_{12}S_2$, this oil appears in garlic in small amounts, but the main constituent of the distillate from garlic is diallyl disulphide, $C_6H_{10}S_2$.¹ In addition to these main constituents there are both lighter and heavier fractions of sulphur bearing oils of uncertain chemical composition but all possessing disagreeable odors.

The taint on the breath after eating onion or garlic is due to the presence of these essential oils or their

decomposition products in the expired air. Considerable uncertainty has existed, however, as to the manner in which the oils are discharged into the expired air. Four theories have been advanced.²

1 That the oils pass into the blood stream during digestion, are then aerated from the blood in the lungs, and so pass into the expired air. For certain volatile substances such as ether, alcohol and acetone this passage from the blood to the air in the lungs is well established. This theory is the one commonly accepted also to explain the source of the odor on the breath after eating onion or garlic, occasionally it is amplified by the addition of a hypothetical secretory activity of the respiratory mucosa by which the oil is believed to be selected from the blood and passed into the air—presumably to account for the fact that the blood, following digestion of garlic, has not been observed to smell of the oil.

2 That the essential oil appears in the saliva by secretion from the blood passing through the salivary glands.

3 That the odor passes from the stomach by way of the esophagus (other than during eructation) and enters the breath through this channel.

4 That possibly the odor arises in part from particles of onion or garlic retained about the teeth, the tonsils and the papillae of the tongue. Considerable attention has been given to pathologic conditions in the structure of the mouth and pharynx as sources of odor on the breath but no one has advanced the idea that after eating onion or garlic the odor arises solely from particles retained in this locality. We, however, do advance such a theory and moreover we here substantiate it with experimental demonstration. The localization of the source of the odor to the mouth structure opens up a possibility of a remedy. No known measure could control the passage of the oils from the blood or saliva to the expired air or prevent their passage from the stomach, it is possible, however, as we shall show, to rid the mouth of the alliaceous oils.

The only extensive experimental work carried out to determine the disposition of alliaceous essential oils in the body was that of Lehmann.³ He estimated the amount of garlic oil appearing in the breath of rabbits after administering the oil subcutaneously, intravenously, rectally and orally. For analytic determination he passed measured amounts of the expired air through hundredth normal permanganate solution and titrated with hundredth normal oxalic acid solution. The doses of oil he used were enormous, from 4 to 5 cc. of the juice pressed from garlic and containing from 8 to 10 mg of the essential oil. This amount would be equivalent to 6 or 8 Gm of the vegetable. Such a dose given to a rabbit weighing 1.5 Kg would correspond to 300 or 400 Gm of garlic given to a man.

Following subcutaneous injection, no oil was detected in the expired air. Following intravenous injection in which the juice was administered over a period of thirty-eight minutes, the expired air gave traces of the oil for a period of fifty minutes, after that time no more appeared on the breath—obviously an effect quite different from the persistent taint observed on the human breath after eating garlic. Following adminis-

tration to the stomach by means of a tube, the amount of oil appearing in the expired air was so slight as to fall within the limit of the error of the method of analysis, definitely less than 1 per cent of the oil appearing in the breath in spite of the massive dose that had been given.

Lehmann's work really offers no support to the belief that the odor on the breath after eating ordinary amounts of onion or garlic comes from the blood by way of the lungs or salivary glands or from the stomach through the esophagus. It offers no explanation for the persistent odor on the breath after the vegetables are eaten.

We have approached the problem in another manner and with an experiment that is crucial. One and five-tenths grams of raw garlic was chewed and swallowed. The breath was immediately rendered foul and remained so for more than twenty-four hours. When the odor was no longer detectable, the same amount of garlic was chopped into small particles and inclosed in gelatin capsules, the capsules were swallowed. No odor whatever was detected on the breath at any time during the next twenty-four hours. The only exception occurred when, during the first three hours after eating the garlic, the subject belched only momentarily then was the breath rendered foul by the odor from the stomach—indicating beyond question that the capsules had dissolved and discharged their contents.

Several repetitions of these experiments gave in each case the same results. Moreover the substitution of 20 Gm of onion for the garlic (in a correspondingly larger number of capsules) gave the same results as those obtained with garlic.

The conclusions appear obvious: the odor of onion or garlic on the breath does not come from the blood stream, from the salivary glands or from the stomach (except at the moment of eructation), it comes instead as an emanation from particles retained by the structures in and about the mouth.

The experiments were amplified by quantitative analysis of the expired air for the following reasons:

1 To substitute actual numerical values for the rough subjective impressions obtained by merely smelling the breath.

2 To allow a critical study of the effect of certain deodorants on the sources of the odor in the mouth. Quantitative methods were particularly desirable in regard to the latter study, for if the deodorant itself possess an odor it is difficult to tell by the sense of smell whether the onion odor is removed or merely masked.

There is no highly sensitive quantitative method of analysis specific for onion or garlic oil. The iodine pentoxide method for estimating volatile organic substances, previously described in papers from this laboratory,⁴ for use in determining small amounts of ether, alcohol and carbon monoxide, is much more sensitive than the permanganate method used by Lehmann. Neither method is specific for onion or garlic oil but responds to all oxidizable organic vapors. This disadvantage was overcome, however, by determinations made on the breath of the subject prior to each experi-

ment to show freedom from all such substances. Likewise in testing deodorants it was necessary to carry out suitable control experiments to prove that no volatile organic substance appeared from the deodorant.

In this method of analysis the air containing the organic vapor is drawn by suction through a tube packed with alternate layers of glass wool and iodine pentoxide (I_2O_5) heated in an electric oven to a temperature of 180°C. The vapor is oxidized, the iodine (in some cases also hydriodic acid)^{4c} liberated passes on in the stream of air and is collected in an aqueous solution of potassium iodide and titrated with standardized thio-sulphate solution in the presence of starch.

Theoretically 1 mg of the diallyl disulphide from garlic should yield 5.8 mg of iodine, and 1 mg of the allyl-propyl disulphide from onion, 6.09 mg of iodine. Both onion and garlic contain in addition to these main volatile ingredients, closely allied odoriferous organic sulphur compounds of greater or lesser volatility. The method of analysis was therefore standardized against the distillate from the vegetables rather than from the commercial oils. To this end a carefully weighed piece of the vegetable (in each of several experiments averaging about 0.1 Gm) was placed in a small flask through which passed the stream of air leading to the tube containing the heated iodine pentoxide. The flask was heated by immersion in a water bath. All connections in the circuit were made glass to glass to avoid exposure of rubber tubing that might absorb the oils distilled from the onion or garlic. Twenty minutes sufficed to remove all the oil from the vegetable as shown by cessation of iodine liberation from the pentoxide.

The results from four experiments carried out on garlic gave closely corresponding results with an average of 10.93 mg of iodine liberated per gram of garlic. This amount of iodine corresponds theoretically to 19 mg of diallyl disulphide (all of the oil considered to be in this form) thus indicating a yield of 0.19 per cent. The yields of oil collected from crude distillation of garlic are only about half this amount.⁵ By the method employed here a higher yield would be expected since there is no loss from failure of condensation of even the most volatile fractions.

The same procedure carried out for onion gave 2.98 mg of iodine per gram of onion or, calculated as allyl-propyl disulphide, 0.049 per cent of oil.

As judged from the sense of taste there is considerable variation in the content of essential oil in different onions, but probably less difference in garlic. The onion used throughout the experiments reported here was an ordinary culinary onion of domestic growth, of medium size and fairly pungent.

In the first series of quantitative experiments, 15 Gm of garlic was chewed and swallowed. Five minutes later and each hour following for a period of six hours, a measured amount of expired air (from 5 to 15 liters) was passed through the iodine pentoxide and the liberated iodine collected and titrated. To obtain the measured amount of air a tube of large bore connected to the pentoxide container was held in the mouth and closed by the tongue during inspiration but left open during expiration, beyond the absorber containing the potassium iodide for collection of the liberated iodine, a gas meter was placed in the circuit, the effluent passage of the meter was attached to the

⁵ Parry, Lehmann.

suction pump, which drew the stream of air through the analyzer train. During each expiration about 50 cc of air was drawn through the pentoxide, when the meter registered the desired total, fresh air was passed through the train for five minutes in order to flush it. The results of three experiments, in each of which 1.5 Gm of garlic was eaten, are given in table 1, which also shows the results from the second and third series of experiments. It will be seen that, five minutes after the garlic was eaten, each liter of expired air contained from 0.0028 to 0.0035 mg of oil, recorded as diallyl disulphide⁶. One hour later the content had fallen to only 0.0008 to 0.001 mg. Thereafter the decline was gradual, six hours after eating the garlic the breath contained from 0.00015 to 0.00025 mg of the oil. This amount was easily detected by the sense of smell.

As a control on these experiments, a second series was carried out in which 1.5 Gm doses of garlic were swallowed in capsules. In no instance was the slightest trace of oil found in the expired air.

In each of a third series of experiments, 1.5 Gm of garlic was chewed and then as completely as possible spit out, the mouth was rinsed with water and the concentration of essential oil in the expired air estimated as in the previous experiments. The amounts found were almost identical with those of the first series in which the garlic was chewed and swallowed.

A somewhat different procedure was carried out for onion. In the first experiment 2 Gm was eaten and the oil in the expired air determined as in the case of garlic, in the second experiment the procedure was repeated except that 20 Gm of onion was eaten. If all the odor arose from particles retained in the mouth, the total amount of onion eaten should make little difference in the odor given off, since only a limited amount can be retained in the structure about the mouth. If, on the other hand, the oil passed into the breath from the blood stream, the amount in the breath

the proportion of 0.0005 and 0.0030 respectively, or 1 to 6. These values correspond approximately to the relative amounts of oil obtained by direct distillation of these two vegetables and given in the foregoing as respectively 4.9 and 19 mg per gram.

From these observations it is clear that the source of odor after eating onion and garlic is from particles retained in the mouth structure. If so it should be possible to remove or deodorize these particles. Brushing the teeth has often been advocated in overcoming

* In each experiment 1.5 Gm of garlic was chewed and swallowed the amount of essential oil in the breath was determined at intervals as indicated. The procedure intended to deodorize the mouth was applied one and one-half hours after the garlic was eaten.

the odor of onion. To test this procedure quantitatively, 1.5 Gm of garlic was chewed and swallowed and the amount of essential oil in the expired air determined five minutes, one hour and one and one-half hours later. During this time the concentration of the oil had fallen to the plateau level (as shown in experiments of series A and C, table 1) in which its further course could be predicted. The teeth and tongue were then brushed with soap and water and the mouth rinsed. The commercial dentifrices were avoided here because the essential oils which they contain liberate iodine from the pentoxide. As seen from experiment A in table 2, no marked decrease in the garlic odor was obtained with the use of soap and water.

From previous work in this laboratory with chlorine in the destruction of organic odors,⁷ attention was turned to the possibilities of this substance in the form of chloramine. After garlic had been eaten the teeth were scrubbed, the tongue brushed and the mouth rinsed with a solution made by dissolving one 4.6 grain (0.3 Gm) chloramine⁸ tablet in each 30 cc of water. Particular attention was paid to the tongue, for the papillae at the base of this structure have long come under suspicion as a source of odor from retained food particles.⁹ No odor of garlic could be detected on the

should be proportioned to the amount eaten. Five minutes after the eating of 2 Gm of onion the breath contained 0.0005 mg of oil, calculated as allyl-propyl disulphide, per liter of air, five minutes after the eating of 20 Gm of onion it contained 0.00056 mg of oil—essentially the same amount. Four hours later these amounts had fallen to 0.00002 and 0.00003 mg respectively, the odor was still detectable by the sense of smell.

The relative amounts of oil found in the breath after the eating of onion and garlic are approximately in

6 Actual numerical values are of significance only in showing the rate at which the odor leaves the breath, there are undoubtedly wide variations in the amount of oil found on the breath of different subjects.

7 Henderson, Yandell and Haggard, H. W. The Elimination of Industrial Organic Odors. J. Indust. & Engin. Chem. 14: 548, 1922. The use of chlorine water in deodorizing the nose and mouth is described by French, as quoted in Solis-Cohen, Solomon and Githens, T. S. Pharmacotherapeutics, New York: D. Appleton Company, 1928, p. 537. Suspension of chlorinated lime in water, dilute chlorine water or a solution of chloramine in water as described later will rid the hands of the odor from onion or garlic. The senior author was able to remove quickly from the skin all trace of the odor from the discharge of a skunk (accidentally received) with the use of a strong suspension of chlorinated lime in water.
8 Paratolene sodium sulphonchloramide Chloramina, U. S. P. The tablets used here were those prepared by the Abbott Laboratories and bearing the name Chlorazene.
9 Hopmann, Eugen. Uebler Mundgeruch, Munchen med. Wchnschr. 79: 1895 (Nov. 4), 1932. Wagner, Richard. Zungenreinerger zur Behandlung sibilen Mundgeruches, ibid. 79: 2049 (Dec. 16), 1937. Prinz, H. Halitosis Cause and Prevention. Dental Cosmos 72: 700, 1930.

breath but there remained a slight odor from the chlorine products. The question of whether the garlic odor was actually destroyed or simply masked was determined by analysis of the expired air.

Experiments were carried out first as controls to determine whether the chlorine odor liberated iodine from the pentoxide. The expired air of a subject who had not eaten garlic was first passed over the pentoxide to confirm the absence of any organic vapors. Next the teeth and tongue were washed and the mouth rinsed with the chlorine solution. The expired air was again passed over the pentoxide. No iodine was liberated, the chlorine odor did not affect the pentoxide.

In each of three experiments, series C of table 2, 15 Gm of garlic was chewed and swallowed and the amount of oil in the expired air followed for one and one-half hours as in the case of experiments of series A, table 2. During this time the oil had risen to concentrations ranging from 0.0027 to 0.0036 mg per liter and fallen to the plateau level of from 0.0008 to 0.0011 mg. The mouth was then treated with chloramine solution as described. Repeated analyses during the next three hours showed absence of oil in the expired air. The chlorine products had deodorized the garlic particles.

Two additional experiments were carried out in which, after garlic had been eaten, the teeth and tongue were brushed and the mouth rinsed with 30 per cent solution of alcohol in water. Control experiments demonstrated that the vapors of alcohol, after the mouth had been washed with this substance, persisted in the breath for only fifteen to twenty minutes. In some proprietary mouth washes recommended for the removal of onion odor the only possible deodorant is the alcohol, which might conceivably dissolve and remove the essential oils. Our experiments, series A, table 2, show that alcohol is without effect on the garlic odor. It would appear that the only effective part played by proprietary mouth washes containing alcohol is in masking the breath by the odor of the essential oils with which they are flavored and which are held in solution by the alcohol.

CONCLUSIONS

The odor given to the breath by onion or garlic comes from the essential oil contained in these vegetables.

The oil does not, as has been suggested, reach the breath from aeration of the blood in the lungs, from pulmonary secretion, from salivary secretion, or in air passed from the stomach. It arises solely from particles of onion or garlic retained in the structure about the mouth.

Quantitative experiments demonstrate this fact.

The particles from which the odor arises can not be removed completely by mechanical means, brushing the teeth and tongue and washing the mouth with soap and water fail to deodorize the breath. Similarly washing the mouth with a 30 per cent solution of alcohol is ineffective.

The breath can be immediately and completely rid of the odor by washing the teeth and tongue and rinsing the mouth with a solution of chloramine. The chlorine liberated in the mouth reacts chemically with the essential oils and deodorizes them.

It is probable that many cases of foul breath from other causes would be amenable to the same method of treatment.

DIABETES MELLITUS AND HYPERTHYROIDISM

REPORT OF A CASE WITH A FASTING BLOOD SUGAR OF 1500 MG PER HUNDRED CUBIC CENTIMETERS IN THE ABSENCE OF COMA

MAURICE BRUGER, MD

Associate in Medicine Assistant Attending Physician and Harriet
Weil Fellow New York Post Graduate Medical School
and Hospital
NEW YORK

This case is presented to record a fasting blood sugar of 1500 mg per hundred cubic centimeters in a diabetic patient without coma but manifesting all the signs and symptoms of marked hyperthyroidism. An extreme hyperglycemia of this degree has been observed infrequently in diabetes (the literature is summarized in the table), not one of the published cases was complicated by thyrotoxicosis. As far as I could learn, this is the only case on record of diabetes complicated by hyperthyroidism showing a blood sugar over 1000 mg per hundred cubic centimeters without any signs of coma although in the present case coma undoubtedly was impending.

REPORT OF CASE

Mrs. L. J. White, aged 43, a seamstress, seen Sept. 13, 1929, complained of pruritus vulvae and vulvar boils. One month previously there had been a surgical intervention for an infected finger and at that time sugar was found in the urine. The past, personal and family histories were irrelevant.

Physical examination showed that the patient was 14 pounds (6.4 Kg.) overweight, that there was slight recession of the gums, that the tonsils were irregular, and that systolic murmurs were present at the apex and base of the heart, otherwise the examination revealed nothing of note. The urine showed a specific gravity of 1.017, no sugar, no diacetic acid and no albumin, microscopic examination was negative. Blood chemistry showed fasting blood sugar 167 mg per hundred cubic centimeters, urea nitrogen, 12.4 mg, and plasma cholesterol 169 mg.

The patient was given a diet containing 80 Gm of carbohydrate, 60 Gm of protein and 140 Gm of fat (total calories 1820). The diet was well tolerated and the urine remained free from sugar without the use of insulin. Her condition remained practically unchanged until July 1932, when she complained of palpitation and loss of weight.

Physical examination at this time revealed moderately prominent eyeballs, tremor of the fingers, an irregular and nodular enlargement of the thyroid gland and auricular fibrillation. The basal metabolic rate was plus 42 per cent, the fasting blood sugar was 227 mg per hundred cubic centimeters. A diagnosis of hyperthyroidism complicating diabetes mellitus was made. Measurable quantities of sugar appeared in the urine and from 8 to 16 units of insulin was prescribed daily. Thyroidectomy was advised but refused by the patient. Roentgen treatments of the thyroid were instituted in its place and in January 1933, following five exposures the basal metabolic rate fell to plus 8 per cent. In spite of the decrease in the basal metabolic rate, increasing quantities of insulin were required to keep the urine free from sugar. In July 1933, because of gain in weight, a diet containing 65 Gm of carbohydrate, 80 Gm of protein and 40 Gm of fat (total calories 940) was ordered, at this time, she was taking 38 units of insulin daily.

In September 1933, following a vacation of two months in the country with more or less self treatment, she returned to the office complaining of weakness, palpitation and marked loss in weight. The pulse rate was 134 per minute and completely irregular. The skin was dehydrated and the eyeballs were moderately soft. There was a slight acetone odor to the breath. The night and morning urines showed 5 and 36 per cent of

From the Department of Medicine New York Post-Graduate Medical School and Hospital

sugar, respectively, and appreciable quantities of acetone in both. The fasting blood sugar was 1,500 mg per hundred cubic centimeters (checked and rechecked by the method of Folin and Wu), the plasma cholesterol 675 mg and the basal metabolic rate plus 59 per cent. A temporary dietary change and increased insulin dosage were instituted, and the patient was admitted to the New York Post-Graduate Hospital the following day.

The subsequent course may be summarized briefly as follows. Glycosuria, acetonuria and loss in weight persisted for several days following admission to the hospital, in spite of an increase in the diet to 230 Gm. of carbohydrate, 75 Gm. of protein and 300 Gm. of fat (total calories 3,920) and 210 units of insulin daily. Ten days following admission the basal metabolic rate had fallen to plus 20 per cent and the fasting blood sugar ranged from 210 to 255 mg per hundred cubic centimeters.

October 5, a subtotal bilateral resection of the thyroid gland was performed by Dr C G Heyd. The examination of the excised thyroid gland revealed multiple adenomas.

The postoperative course, especially for the first few days, was stormy but the patient eventually made a good recovery and was discharged from the hospital seventeen days following the operation. For three days prior to her discharge the urine was free from sugar on a diet containing 100 Gm. of carbohydrate, 70 Gm. of protein and 90 Gm. of fat (total calories 1,490), and 45 units of insulin daily. Since November 1933 she has been followed in the metabolic clinic of the New York

dence has been presented to show that hyperthyroidism adversely influences the course of diabetes. Pollack⁸ and MacBryde⁹ have recently reviewed the subject of insulin resistance and they consider hyperthyroidism to be the responsible factor in many cases of diabetes that are refractory to insulin. This is to be expected, since the advent of hyperthyroidism in a patient with diabetes as exemplified by the present case, "creates abnormal demands upon an already inefficient carbohydrate metabolism both by virtue of an elevation of the basal metabolism and by enhancement of glycolysis."¹⁰

As indicated in the case report for the first few days following the thyroid resection the clinical condition of the patient was precarious and she continued to be markedly refractory to insulin. Several days later, however, the patient responded more favorably to insulin and the daily dose could be gradually reduced. A similar case exhibiting extreme postoperative resistance to insulin in a diabetic patient with hyperthyroidism was recently reported by Hills, Sharpe and Gay.¹¹

In the majority of cases, hyperthyroidism precedes the onset of diabetes. John⁷ has developed the Naunyn-von Noorden hypothesis to the extent that he

Post-Graduate Hospital, and her condition has been entirely satisfactory to the day of writing. The last study, carried out approximately one year following the thyroidectomy, showed the weight average normal, basal metabolic rate minus 6 per cent, pulse 78 per minute and regular, and the urine free from sugar or, at most, traces in fractional specimens. The diet was approximately 150 Gm. of carbohydrate, 70 Gm. of protein and 90 Gm. of fat (total calories 1,690), and the dosage of insulin was 44 units daily.

COMMENT

The association of diabetes and hyperthyroidism is frequently encountered in large clinics, although as recently as 1931 Ginsberg¹ remarked that comparatively few cases have been reported in the literature. Fitz,² Allen,³ Boothby and Wilder,⁴ Wilder,⁵ Joslin and Lahey⁶ and John⁷ have made pertinent contributions on the clinical aspects of this subject, and much evi-

believes that hyperthyroidism per se does not lead to a disturbance in carbohydrate metabolism, in patients with a predisposition to diabetes (diabetic "anlage"), however, the development of hyperthyroidism and the resultant demands of an increased metabolism brings about a true diabetes in the same manner as infection or obesity would in the same individual. The clinical observations of John and the experimental studies of Shpiner¹² lend proof to the validity of this hypothesis. The present case, however, does not belong to this category. This patient manifested all the signs and symptoms of true diabetes mellitus approximately three years before any evidence of hyperthyroidism developed. The advent of the thyrotoxic state so upset the already impaired carbohydrate metabolism that very large doses of insulin were required to bring the diabetic condition under control and to permit thyroidectomy.

TREATMENT OF RHEUMATOID ARTHRITIS WITH FEVER INDUCED BY DIATHERMY

A FOLLOW-UP STUDY

CHARLES L. SHORT, MD

AND

WALTER BAUER, MD

BOSTON

Since the preliminary report by Neymann and Osborne¹ in 1929 of the employment of high frequency currents in the production of fever, the therapeutic use of this method has been rapidly extended to various chronic diseases. At the same time, other methods such as the use of short radio waves and radiant and conducted heat have been employed, all successful in raising and sustaining a patient's temperature in a controlled manner. That chronic arthritis should have been one of the first diseases to be tried seems natural, since local heat to the joints, hot baths and fever induced by typhoid vaccine have long occupied a prominent place in its therapy. It is our purpose in this paper, after briefly reviewing the published reports of others who have utilized artificial fever, to summarize the end results in twenty-five cases of rheumatoid (atrophic) arthritis treated with fever produced by general diathermy. It is to be noted at this point that, in both our own cases and those cited from the literature, we have confined ourselves to rheumatoid or atrophic arthritis, sharply excluding both purely hypertrophic arthritis and that due to a specific organism, such as the gonococcus.

In 1932 Neymann and others,² using general diathermy, obtained definitely beneficial results in a total of 64 per cent of two groups, one of six patients followed for twenty months, and one of five followed for a year or less. They ascribed their success to the giving of eight weekly treatments with temperature sustained at 104 F for at least ten hours and believed that briefer courses (two or three hours at 103 F or less) were of no value. In the same year Tenney,³ using short radio waves, reported fourteen out of sixteen patients with rheumatoid arthritis definitely helped. In his paper, no details of treatment or duration of follow up are included. Bierman⁴ in 1933 stated that patients given a fever of 105 to 106 F for several hours with the radiotherm, although showing marked temporary improvement, relapsed at least partially after a day or two. Further gain was seen, however, after successive treatments, and at the end of the series there was usually definite improvement. About the same time Berns⁵ treated eleven cases of rheumatoid arthritis, the average course comprising eight treatments

with temperatures of 102.5 F for three and one-half hours. Only 28 per cent of these showed no gain, and he reports 36 per cent both objectively and subjectively improved and another 36 per cent only subjectively improved. King⁶ also reported striking results in rheumatoid cases treated at 104 F for two hours or more and stated that recurrences were caused by too long intervals between treatments. In two groups of patients, one of sixteen followed for about two years and another of twenty followed for about a year, Kohn and Warren⁷ found that all but two derived definite benefit from one or more treatments with general diathermy. (The temperature maintained and the duration of treatments were not stated.) Three cases which relapsed later showed improvement with another treatment. In direct contrast to the startling results thus far recorded is the report of Nicholls and Stainsby⁸ published early in 1934. These authors treated twelve patients from one to five times, with fever induced by radiant heat, with temperatures averaging from 104 to 105 F for from three to five hours. At the end of a month or more, only three claimed subjective benefit, which was not substantiated by objective examination. The absence of noteworthy changes in the sedimentation rate of these patients following treatment confirmed the authors' clinical impression.

In table 1 are summarized our results obtained in twenty-five cases of rheumatoid arthritis. These had all been thoroughly studied in the medical wards before treatment was instituted and fulfilled the diagnostic criteria of rheumatoid arthritis. Most of them had received general treatment, including a high vitamin diet, rest, control of pain, physical therapy, and the removal of obvious foci of infection. During the follow-up period, such general treatment as seemed indicated was pursued. They were all given one or more treatments by means of a Victor superpower diathermy machine and the electrodes described by Neymann and Osborne⁹. During application of the high frequency current and after the electrodes had been removed, the patients were insulated with warm air by means of a box containing electric lamps,¹⁰ and their temperatures were thus maintained. They were given fluids at room temperature as desired and were kept more comfortable by cold compresses on the head and the use of an electric fan. A mixture of opium and alkaloids in doses of one-third grain (0.02 Gm) was used also. It is fair to state that the experience was a harrowing one for most of the patients and that treatments were not uncommonly followed by headache, nausea and vomiting, and severe herpes. Patient 9 expressed himself as "knocked out" by the treatment for three weeks. Undoubtedly some of this discomfort was due to the excessive sodium chloride loss in the sweat and could have been eliminated by the oral administration of sodium chloride in the course of the treatment, as advocated by Simpson.¹¹

The age of the patients treated varied from 16 to 58 years, with an average of 36. There were nine males and sixteen females in the series. The average duration of the disease was three and one-half years, with extremes of three months and seventeen years. We took the cases as they came along, so that the series

had vasomotor disturbances, as evidenced by cold extremities, increased sweating and cyanosis, while 24 per cent had arteriosclerosis, demonstrated either clinically or by roentgenograms. In all, seventy-one treatments were given our group of twenty-five patients, with the temperature usually maintained at 104° F. or

TABLE 1—*Clinical Course in Twenty-Five Cases*

Pa- tient	Age Sex	Dura- tion of Disease	Involvement		Limitation	Vascular Changes	Treatments	Duration of Improve- ment	Follow Up	Final Result	Comment
			Soft Tissue	Cartilage							
1	34 ♀	6 yrs	Slight	None	None	Vasomotor	One of 4 hrs at 103° F	None	33 mos	Unchanged	Mild subcutaneous burn
2	27 ♂	5 mos	Moderate	None	Slight	Vasomotor (marked)	Three of 4 hrs at 104-105° F ten of 2-3 hrs at 103° F	16 mos	16 mos	Improved	Still shows definite arthritic changes and unable to work
3	31 ♂	4 yrs	Marked	Moderate	Moderate	Vasomotor (marked) arterio- sclerosis	Three of 4 hrs at 106° F twelve of 2-3 hrs at 103° F	6 mos	14 mos	Worse	Not helped by typhoid vaccine intravenously
4	57 ♀	1.5 yrs	Moderate	Moderate	Moderate	Arterio- sclerosis Vasomotor	One of 4 hrs at 104° F	1 mo	33 mos	Worse	Severe second degree burn
5	26 ♀	2 yrs	Slight	None	None	Vasomotor	Two of 4 hrs at 105° F	23 mos	33 mos	Well	Became pregnant one month after last treatment
6	23 ♀	2 yrs	Moderate	Slight	Slight	Vasomotor (marked)	Two of 4 hrs at 105° F	32 mos	32 mos	Improved	Remission began two months be- fore treatment
7	21 ♀	3 mos	Slight	Slight	Slight	Vasomotor	One of 4 hrs at 106° F	2 wks	33 mos	Unchanged	Initial improve- ment followed by exacerbation of two months in- cluding knee effu- sion then nearly well for over two years followed by another exacer- bation
8	42 ♀	6 yrs	Moderate	Moderate	Moderate	Vasomotor	Two of 4 hrs at 105° F	None	30 mos	Worse	Marked headaches and buccal herpes following treat- ment
9	21 ♂	6 yrs	Marked	Marked	Marked	None	One of 4½ hrs at 103° F	None	36 mos	Unchanged	'Knocked out' for three weeks fol- lowing treatment
10	32 ♀	2 yrs	Moderate	Moderate	Moderate	Vasomotor arterio- sclerosis	Two of 4 hrs at 104° F	3 wks	6 mos	Worse	
11	36 ♂	5 yrs	Moderate	Moderate	Moderate	None	One of 4 hrs at 103° F	1 mo	19 mos	Worse	
12	16 ♀	7 mos	Slight	None	None	Vasomotor	One of 4 hrs at 105° F	9 mos	20 mos	Unchanged	Exacerbation of eight months followed initial improvement
13	53 ♀	6 mos	Moderate	None	Moderate	None	One of 4 hrs at 104° F	18 mos	18 mos	Nearly well	Unusually faithful local and general treatment fol- lowed
14	25 ♀	4 yrs	Marked	Marked	Marked	Vasomotor (marked)	One of 4 hrs at 104° F	None	34 mos	Worse	
15	46 ♂	6.5 yrs	Slight	Moderate	Moderate	None	One of 4 hrs at 103° F	None	37 mos	Unchanged	
16	23 ♀	5 yrs	Moderate	Moderate	Marked	None	One of 4 hrs at 105° F	3 days	35 mos	Worse	
17	42 ♀	1.5 yrs	Moderate	Moderate	Marked	Vasomotor (marked) arterio- sclerosis	Three of 4 hrs at 104-105° F	1 week	33 mos	Worse	Improved for six months after first two treatments ensuing relapse not affected by third treatment
18	36 ♀	4.5 yrs	Moderate	Moderate	Moderate	Arterio- sclerosis	One of 4 hrs at 106° F	6 mos	36 mos	Worse	
19	50 ♂	3 yrs	Slight	Moderate	Slight	Arterio- sclerosis	One of 4 hrs at 105° F	3 days	20 mos	Worse	
20	47 ♂	4 yrs	Moderate	Moderate	Marked	None	Two of 4 hrs at 105° F	3 days	29 mos	Worse	
21	58 ♂	17 yrs	Moderate	Marked	Marked	None	Ten of 4 hrs at 105° F	1 week	33 mos	Unchanged	Unchanged for 14 months improved for 18 months, back to former status in last 6 months
22	31 ♂	2 yrs	Moderate	Moderate	Slight	Vasomotor (marked)	Four of 2-3 hrs at 104° F	2 wks	23 mos	Worse	
23	41 ♀	1.5 yrs	Moderate	Moderate	Moderate	Vasomotor	Two of 4 hrs at 104° F	27 mos	41 mos	Improved	Complicated by ulcerative colitis
24	34 ♀	3 mos	Slight	None	None	Vasomotor	One of 4 hrs at 105° F	2 wks	40 mos	Unchanged	
25	42 ♀	5 yrs	Moderate	Moderate	Moderate	Vasomotor	One of 4 hrs at 105° F	1 mo	30 mos	Worse	

includes both early, mild cases and advanced, severe, crippling types. In table 1 we have attempted to summarize the degree of arthritis before the treatment, with cartilage involvement demonstrated by definite joint narrowing in roentgenograms. It can be seen that all presented soft tissue changes, and nineteen, or 76 per cent, a certain amount of cartilage destruction. In the next column is shown the vascular status of the patient, so important in this disease. Fifteen or 60 per cent,

over for four hours. Patients 2, 3 and 22 were given briefer treatments lasting from two to three hours, at lower temperatures (from 102 to 103° F.)

RESULTS

In twenty out of our twenty-five cases, at least temporary improvement was shown, both subjectively, in freedom from pain and objectively, in increased joint motion and occasionally in decreased effusion and

swelling At times the results were almost miraculous and encouraged greatly both the patients and ourselves. Unfortunately, with few exceptions this improvement was only temporary, and in only five, or 20 per cent, has the gain been maintained to the end of the follow-up period. Table 2 shows roughly the duration of improvement after the course of treatments.

It can be seen from table 1 that patient 21, in the course of over three years' follow up, was unchanged for fourteen months and improved for the next eighteen months, only to return to his former status during the last six months. This illustrates the variable course of the disease and the danger in drawing conclusions after a comparatively brief follow up. Patient 17 was benefited for six months after her first two treatments and then relapsed. She was treated again, with benefit lasting only a week, and has since steadily gone down hill.

An attempt has been made to follow this group of twenty-five patients as carefully as possible after their diathermy treatments. As seen by table 1, nine have been followed for three years or more, nine for two years or more, and all but one of the remainder for over a year. The final survey shows that five or 20 per cent, were improved, seven or 28 per cent, were essentially unchanged while thirteen, or 52 per cent, were worse. Considering the severity of the treatments,

TABLE 2—Duration of Improvement

Duration	Cases
None	5
Up to 2 weeks	5
From 2 weeks to 6 months	6
From 6 months to 1 year	1
From 1 year to 2 years	2
Two years or more	3

these results seem hardly to justify the continued use of this form of therapy.

Of the five patients who improved, one (patient 5) became pregnant within a month after her last treatment and has continued to be free from the disease since. It is well known that pregnancy will frequently induce a remission in rheumatoid arthritis. Patient 6 had apparently started on a remission two months before the treatments were given, although they undoubtedly accelerated her improvement. Patient 13 pursued a course of rest and physical therapy of unusual faithfulness at home following the fever treatments. Thus, in three of our five patients who improved it is not possible to ascribe honestly the gain to diathermy. We have not mentioned these facts in an attempt to deprive fever therapy of any value whatever and realize fully that, in the patients who were unchanged or became worse, deleterious factors may well have been at work. But we do wish to reemphasize the difficulty of evaluating properly any form of therapy in rheumatoid arthritis, that its course is variable and subject to remissions and relapses (the reasons for which can often not be traced) and, finally, that it is exceedingly dangerous to single out any temporary improvement as a cure. Furthermore, we agree with others that the mental attitude of the patient is of the utmost importance in many cases in determining the outcome. Such a radical form of therapy as general diathermy cannot help but impress and encourage the patient, especially if there is a marked immediate gain. This is well illustrated in patient 13, who arrived in the hospital discouraged and with little will to improve.

Her formulation of the decision to undergo this new and radical treatment, as well as carrying through the ordeal itself, undoubtedly pointed the way to a successful course of therapy, largely carried on by her husband and herself at home.

Several patients were given a succession of treatments. Patient 2, a man aged 27, with rheumatoid arthritis of five months' duration, showing definite soft tissue changes but no evidence of cartilage destruction and marked vasomotor instability, first had infected tonsils and teeth removed. He was then given two fever treatments of four hours at 105 F, with definite benefit. He was sent home and became worse in the course of a month, with effusions in both knees and limitation of one elbow. He was then given ten biweekly brief treatments of from 103 to 104 F, lasting about three hours, with subjective and objective improvement. When the patient was seen a year later, this improvement had been maintained, but he still showed definite arthritic changes and was unable to work. Another (patient 3) was a man, aged 31, with a severe, crippling type of rheumatoid arthritis of four years' duration, following trauma, with progressive periarticular swelling and effusion, involving multiple joints, with increasing ankylosis. He also showed marked weight loss, muscular wasting and psoriasis. Synovectomy gave typical pathologic findings of rheumatoid arthritis. He was given three treatments at 106 F for four hours. He then gained 9 pounds (4 Kg), with the aid of insulin. Next he was given twelve biweekly briefer treatments at 103 F, lasting about three hours. These were followed by two transfusions. At the end of this time his general condition was excellent, but his arthritis was slowly progressing, and when seen ten months later he was much worse. A third patient (21) was a man, aged 58 in his third attack of rheumatoid arthritis of fifteen months' duration, over a period of seventeen years. During this period he had three nearly complete remissions, lasting respectively six, two and a half and five years. He showed marked limitation with little active inflammation. General treatment was of some benefit. This was followed by one treatment at 104 F for four hours, with marked relief for two days, followed by a relapse, with swelling of his ankles and feet. Next he was given nine treatments at 105 F for four hours at weekly intervals, with relief from pain each time lasting up to about the time of his next treatment, but little permanent gain at the end of the series. He stood the treatments well except that vomiting followed, not helped by rectal dextrose. He was seen frequently during the next fourteen months and, after following a fluctuating course, was about the same as before the fever therapy. He then showed definite gain in the course of a year without further diathermy treatments, as a result, he believed, of the extraction of infected teeth, but in the last six months he has had another relapse. We have mentioned these cases in order to show that even repeated treatments may not give permanent improvement.

What of the five who improved? Is there any way of foretelling which patients might benefit from this treatment? Briefly, they were younger than the others (three were under 30), their arthritis was of shorter duration, they showed in general little or no cartilage destruction or limitation, and, finally, all but two demonstrated more marked vasomotor changes. Furthermore, in the course of the treatment the increase in pulse pressure, which we believe to be an index of vaso-

dilatation, was more marked than in the group that did not improve. We consider therefore that, in common with other measures which help rheumatoid arthritis, such as the use of typhoid vaccine intravenously, physical therapy and possibly salicylates and ammonium orthoiodoxy benzoate, fever therapy acts by increasing the blood supply of the affected tissue. Berris⁶ and King⁶ agree that the increased peripheral circulation is the important therapeutic factor, while Nicholls and her associates⁸ ascribe the temporary decrease in joint swelling to dehydration of the body.

From the results that we have obtained with our twenty-five cases treated with artificial fever, we are forced to conclude that this method is of only temporary benefit. It is possible of course, that patients given fever for ten hours or more, as advised by Neymann and Osborne,² will fare better, although the increased duration would tend to multiply the dangers and discomforts. We hope that these authors will extend such observations to a larger series of patients. Again, as suggested by our figures, a selected group of young patients, with slight involvement and arthritis of brief duration, might respond successfully. If so, the results could be interpreted with difficulty, since it is just this group that general therapy usually aids.

We have stated before that our series of cases is limited to rheumatoid arthritis, with hypertrophic and gonorrheal arthritis carefully excluded. We have had some experience in the treatment of the latter disease with artificial fever produced by general diathermy or radiant heat. In general, our results have been excellent and far superior to those obtained in rheumatoid arthritis both in immediate relief of pain and inflammation and in leaving the patient with useful joints. We have seen, however, equally favorable end results in patients treated with fever induced by typhoid vaccine intravenously.

SUMMARY AND CONCLUSIONS

1 Twenty-five patients with rheumatoid arthritis were given seventy-one artificial fever treatments by means of general diathermy.

2 The number of treatments given each patient varied from one to fifteen, and the usual temperature maintained was 104 F for four hours.

3 While no patient was seriously injured by this treatment, all looked on it as a harrowing ordeal.

4 Eighty per cent of our cases showed temporary improvement, but in only 20 per cent was this maintained until the end of the follow-up period.

5 When we balance the results obtained against the severity of the treatment, our conclusion is that in rheumatoid arthritis the use of this method is only occasionally justified and should not be used to the exclusion of general treatment.

Photosynthesis—In green leaves the energy of sunshine supports a chemical reaction or reactions (photosynthesis) in which organic compounds such as sugars and starches are synthesized from the simple inorganic substances carbon dioxide (carbonic acid) and water, and the energy of a part of the light is, so to speak, locked up in the foodstuffs thus formed—sugars and starches more indirectly, fats, and still more indirectly, the other organic compounds of our foods. Even in the formation of the sugars and starches photosynthesis is probably a rather complicated and indirect process as it occurs in nature so that laboratory syntheses of sugars probably do not actually duplicate the natural process nor really forecast an era of synthetic food—Sherman H C. Food and Health. New York: Macmillan Company 1934.

THIOGLYCEROL

A MORE STABLE SULPHYDRYL COMPOUND FOR USE IN THE HEALING OF WOUNDS

LEON E. SUTTON, M.D.
SYRACUSE, N. Y.

Reimann¹ in May 1930 reported relatively rapid healing of cutaneous ulcers by means of thiocresol. Later work by Reimann and others seems to confirm his observations. This paper offers observations based on animal experiments and 264 clinical cases treated with Thioglycerol. Thioglycerol seems to have certain advantages over other sulphhydryl compounds that have been suggested for the stimulation of wound healing.

Hammett and Reimann,² as a result of well controlled experiments on plants, rats and mice and finally on man, concluded that sulphur in the form of the chemical group sulphhydryl (SH-) is an essential to cell production. Reimann³ also showed that animal skin could be thickened and the thickness of human skin grafts increased by the application of thiocresol, 0.25 per cent in hydrous wool fat. Birnbaum⁴ reported favorable results from the use of thiocresol on a variety of denuded surfaces and on skin grafts. Brunsting and Simonsen⁵ confirmed the observations of Reimann and Hammett concerning the stimulating properties of certain sulphhydryl-containing compounds. They found that cysteine, in water solution stimulated granulation tissue and epithelium and seemed to inhibit bacterial growth. Their conclusions were based on more than 200 cases at the Mayo Clinic.

All sulphhydryl compounds so far suggested for the stimulation of wound healing have the disadvantage of being very unstable. Their solution must be freshly made and dressings changed frequently. Granulations grow more rapidly than epithelium and must be reduced before epithelium can advance. Search was therefore made for a more stable sulphhydryl compound and a simple method of controlling the growth of granulation tissue.

THIOGLYCEROL

Thioglycerol ($\text{CH}_2\text{OHCHOHCH}_2\text{SH}$) was produced by Gelormini⁶ in June 1931 by treating glycerol alpha chlorhydrine with potassium hydrosulphide under pressure and in alcoholic solution. Thioglycerol deteriorates less than 10 per cent a month at room temperature but liberates sulphhydryl more rapidly at body temperature. It has a hydrogen sulphide odor and physical properties similar to those of glycerin.

CLINICAL RESULTS

Since June 1931, Thioglycerol has been used in 264 clinical cases (shown in the accompanying table), including a variety of wounds and ulcers. Photographs

were taken in some cases, in others measurements were made at intervals during the healing process. Only a few with control wounds were available. A 1:5000 solution of Thioglycerol in glycerin was used in most instances, but the percentage of glycerin was varied

gross evidence of epithelial advance was evident within forty-eight hours and was continued unless interrupted by unfavorable conditions. In general, the rate of healing seemed to be proportional to the area of the wound, as shown by Carrel and Hartmann.⁷

Thioglycerol in glycerin or water-soluble jelly has been used to stimulate the healing of extensive, deep burns having islands of epithelium, after the necrotic tissue has separated. The following case is an example.

CASE 1—A woman, aged 28, was severely burned in a fire March 6, 1932. The face and hands received second degree burns. The lower extremities, from the hips to the soles of the feet, were completely involved, more than 70 per cent of the total area being third degree burns. A tannic acid crust was produced on the legs. The crusts were removed because of purulent accumulations beneath them, and sodium hypochlorite (Dakin's) solution was applied to remove remnants of crust. March 18 there was very little healing of the third degree areas. Thioglycerol (1:5000) in glycerin was then applied on six layers of gauze and covered with waxed paper. Dressings were changed daily. Every third or fourth day, adhesive strapping was substituted for the Thioglycerol. Healing was complete on April 11, and the patient went to a dance ten days later. Examination nine months later showed the scars to be soft and movable. Her sister, two years older, was burned in the same fire. The burns showed almost the same distribution and depth except that there were fewer islands of epithelium. Her legs were grafted on two occasions; large thin grafts being used. Eighty-five per cent of the surfaces were thus covered. Thioglycerol was not used on this patient.

Fig. 1 (case 3)—Burn of the axilla after three weeks treatment with Thioglycerol

according to the age of the wound and the condition of the granulating surface. Most of the ambulatory cases were treated with Thioglycerol in mucilage of tragacanth. This combination was also used on recent burns and other sensitive surfaces. Hydrous wool fat (lanolin) containing 0.25 per cent of Thioglycerol was used to thicken the epithelium of recently healed ulcers and large, thin (Ollier-Thiersch) grafts, as suggested by Reimann.⁸

Healing in Two Hundred and Sixty-Four Clinical Cases Treated with Thioglycerol

	Old Lesions		Recent Lesions		Preliminary Treatment		Sensitive		Satisfactory		Unsatisfactory		
	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent	
Bed patients	123	83	68	40	32	75	61	3	2.5	113	92	10	8
Ambulatory patients	141	107	76	34	24	96	68	2	1.4	121	86	20	14
Total cases	264	190	72	74	28	171	65	5	1.9	234	89	30	11

In tabulating the results of treatment of the clinical cases, healing was considered satisfactory when failure to heal under ordinary treatment was followed by relatively rapid healing under treatment with Thioglycerol. Sixty-five per cent of the cases required some preliminary treatment such as improvement of drainage or removal of necrotic tissue. Evidence of irritation or sensitivity was present in five cases, or 1.9 per cent. Healing was unsatisfactory in thirty of the 264 cases. Of these, twenty were ambulatory and ten were bed patients. Lack of cooperation was evident in eight of the ambulatory cases. Two bed patients had large, unhealed burns of months' duration. Both of them seemed to be sensitive to sulphidryl, and treatment was discontinued. In the remaining twenty unsatisfactory cases, healing ceased or progressed very slowly as the wound area became small. In the satisfactory cases

Fig. 2 (case 3)—One year after complete healing

Healing between the grafts was very slow and not complete until May 22. Nine months after healing of the grafts she still complained of swelling and itching of the legs.

Included in this series were several electrical burns and a number of chemical burns. Case 2 is one of electrical burns.

⁷ Carrel, Alexis, and Hartmann, Alice. *Cicatization of Wounds*. J. Exper. Med. 24: 429 (Nov.) 1916.

CASE 2—A boy, aged 9 years received electrical contact burns on the backs of both feet May 30, 1931. He was admitted to the University Hospital three weeks later because the wounds had not begun to heal. They were free of necrotic tissue, but the extensor tendons were exposed on one foot, while the fifth metacarpal bone and a proximal phalanx of the other foot were partly exposed. Thioglycerol (1:5,000) in pure glycerin was used on one foot and pure glycerin on the other, the dressings being changed once a day. The wound treated with Thioglycerol showed activity at forty-eight hours and was about 40 per cent healed in twelve days. The control wound remained clean and there was a slight advance of epithelium. The treatment was then reversed. Within ten days healing was about even in the two wounds.

Fig. 3 (case 4)—Burn of the leg. Result of fifteen days' treatment with Thioglycerol.

The frequency with which deep burns involving the arm, chest and axilla result in loss of function through scar contracture is well known. Such a case, in which healing occurred without loss of function is illustrated in case 3 (figs. 1 and 2).

CASE 3—A girl, aged 8 years, was burned by fire Nov. 1, 1931. She was sent to the hospital November 21 because the wound was not healing. There was a deep burn of the proximal half of the arm, anterior fold of the axilla, and a small part of the chest wall. The Carrel-Dakin technic was used for ten days until necrotic tissue had separated. Thioglycerol was then applied as in the previous cases. Three weeks later (fig. 1) the area was 90 per cent healed. At five weeks, healing was complete and the arm could be thrust upward without limitation. Examination one year later (fig. 2) showed a soft scar without tension.

CASE 4—A girl, aged 7 years, caught her leg between a hot radiator and the wall Nov. 19, 1931. When the leg was excircuited an extensive third degree burn of the calf involving almost the entire circumference of the leg, was found. Figure 3 shows the degree of healing after fifteen days' treatment with Thioglycerol (1:5,000) in 70 per cent glycerin. The Carrel-Dakin technic was used for six days to remove necrotic tissue before Thioglycerol treatment was started. The area was entirely covered with epithelium December 28, thirty-nine days after the injury.

ANIMAL EXPERIMENTS

Technic—Male white rats weighing about 100 Gm were used. The rats were anesthetized with ether. The abdominal skin was shaved and scrubbed with soap solution and ether. A circular piece of abdominal skin, about 2 cm in diameter was excised from each side of the abdomen with scissors. Each wound was covered with four layers of sterile gauze. Rubber dam was placed over the gauze, fixed to the skin between the wounds with rubber cement and continued around to the back, where it was fastened by lacings. Solutions to be tested were introduced through holes in the rubber. Glycerin solutions were introduced but once in twenty-four hours, other solutions every two hours. Every fourth day the rats were anesthetized, the dressings opened and the wound areas recorded by means of a camera lucida and a planimeter.

Thiocresol—Two experiments were carried out, twelve and sixteen white rats being used. One wound was treated with thiocresol 1:10,000 in water solution while physiologic solution of sodium chloride was applied to the control wound. Granulations were not reduced.

1 The wounds treated with thiocresol healed 18 per cent faster than the control wounds.

2 Slight superficial necrosis of the granulations was seen in the wounds treated with thiocresol.

Glycerin—Clinical experience with the use of glycerin on granulating wounds suggested that, because of its dehydrating action, glycerin might retard the exuberant growth of granulation tissue. To determine the effect of glycerin on granulating tissue six white rats were used. One was treated with pure glycerin and the other with saline solution.

Granulations grew rapidly in the wounds treated with saline solution. In those treated with glycerin the granulations remained relatively level. Necrosis was absent from both wounds. Glycerin was therefore selected as the vehicle for Thioglycerol experiments.

Thioglycerol—Three series of rat experiments, with ten, twelve and sixteen rats were carried out. Thioglycerol was used in pure glycerin and the controls were treated with pure glycerin only. The purpose of the first series was to determine the optimal dilution of Thioglycerol. A dilution of 1:5,000 seemed to give the best results. This dilution was therefore used in the second and third series.

1 A dilution of 1:5,000 seemed optimal.

2 The wounds treated with 1:5,000 Thioglycerol in glycerin healed 21 per cent faster than those treated with glycerin alone.

CLINICAL RESULTS WITH THIOCRESOL

The clinical use of parathiocresol as suggested by Reimann,¹ was begun in June 1930. Thirty-two patients having sluggish granulating wounds were selected. These wounds were treated with 1:10,000 water solution of thiocresol. The following observations were made: 1 In every case epithelium advanced until unfavorable granulations were reached. 2 Granulations developed so rapidly that the advance of epithelium was checked. 3 After forty-eight hours' treatment, slight superficial necrosis of the granulating surface was evident in twenty-six of the thirty-two wounds. 4 Because of the instability of thiocresol, water solutions must be freshly made and the dressings moistened frequently.

CLINICAL USE OF THIOGLYCEROL

For the treatment of ambulatory patients, Thioglycerol (1:5,000) in mucilage of tragacanth is used. A layer of the tragacanth mixture one-fourth inch in thickness, is applied directly to the wound on four layers of gauze, covered with some impervious material such as cellophane or rubber, and bandaged in place. This dressing is changed once in twenty-four hours.

If the patient is not ambulatory, Thioglycerol (1:5,000) is used in pure glycerin, 70 per cent glycerin

or water solution, depending on the character of the granulating surface. When the granulations are level with the epithelial edge, 70 per cent glycerin is the solvent used. If they are redundant or pale, pure glycerin is used. But if they are below the skin level a water solution of Thioglycerol (1:5000) is injected every two hours through tubes fixed in the dressing. When glycerin is used six layers of gauze are saturated with the solution and covered with impervious material. These dressings are changed once in twenty-four hours.

In both the ambulatory and the bed cases best results will be obtained by the intermittent treatment as suggested by Reimann.¹ This may be done by changing to adhesive stripping glycerin or saline solution for twenty-four hours every two or three days.

Wounds should be laid wide open so that healing may progress from the bottom. No satisfactory solvent of necrotic tissue has been found for use in the ambulatory cases. In hospital cases the Carrel-Dakin technic is used until necrotic tissue is removed. High granulations may be shaved down with a razor blade if they are not too sensitive or silver nitrate may be applied and followed by pepsin-hydrochloric acid solution, as advised by Reimann.²

The part should be kept warm, protected from trauma and immobilized if possible. Elevation, elastic pressure or stripping may be indicated to improve circulation. Systemic conditions that may interfere with healing should not be neglected. Large defects will require skin grafting. Very old ulcers with poor local circulation will heal more rapidly after excision. Overhanging edges that have become covered with epithelium may be excised. Granulations must be relatively level, free from necrotic tissue, red and firm.

CONTRAINDICATIONS

Sulphydryl compounds should not be used if a malignant condition is suspected. Treatment should be discontinued if signs of skin irritation appear. Prolonged application of sulphydryl compounds to skin grafts may cause excessive thickening of the grafts and contracture of the grafted area.

COMMENT

There are many factors in the healing process, which vary not only in different individuals but in the same individual at different times. Careful observation of the healing wound will often lead to a change in treatment. Correction of conditions that retard repair should take precedence over the use of measures to stimulate healing.

Thioglycerol has been used for several months at the Mayo Clinic³ with satisfactory results.

Sensitivity to sulphydryl was observed in only five of 264 cases. Reimann⁴ observed sensitivity in eighteen of 450 cases in which he painted the skin of the arm with 1 per cent alcoholic solution of thioresol.

Thioglycerol seems to offer the following advantages over other sulphydryl compounds in the stimulation of wound repair:

1 In its original state or dissolved in pure glycerin, Thioglycerol retains its clinical activity for more than six months when kept at room temperature.

2 Dissolved in glycerin or in a water-soluble base, it need be applied but once a day. It is therefore available for ambulatory patients.

3 The use of glycerin as a vehicle seems to hold granulations in check and allow the epithelium to advance.

CONCLUSIONS

1 The work of Reimann on the stimulation of wound healing by sulphydryl is confirmed.

2 Thioglycerol is a relatively stable sulphydryl compound that can be used for the stimulation of wound repair in ambulatory as well as in hospital cases.

Clinical Notes, Suggestions and New Instruments

OBSTRUCTION OF A CORONARY ARTERY DUE TO THE PRESSURE FROM A CALCIFIED NODULE IN THE MYOCARDIUM

FREDERICK W. NIEHAUS, M.D., OMAHA

Assistant Professor of Medicine, University of Nebraska College of Medicine

Coronary occlusion due to disease of the coronary arteries has been extensively studied and described. Calcified nodules¹ in the myocardium have also been investigated, even by the less recent pathologists. Monckeberg² mentions disturbances of conduction due to such nodules by pressure on or by involvement of a branch of the conduction system. Hochrein³ points out that calcified stenotic mitral valves, by distorting the sinuses of Valsalva, may more or less interfere with the coronary circulation. A fairly extensive search of the literature

Fig. 1—Electrocardiogram of May 17, 1933, showing a marked elevation of the ST segment in the chest lead IV indicating a coronary occlusion. Atrial fibrillation is also present.

fails to reveal a record of an obstruction of a healthy coronary artery due to pressure from a source outside the vascular wall. This seemed justification for recording the following case.

H. T. M., a man, aged 42, admitted to the Lutheran Hospital, May 12, 1933, in the service of Dr. H. A. Wigton, was having delusions of persecution and was restrained with considerable difficulty. His temperature was 100.6 F. Because there was evidence of disturbed cardiac function, the psychosis was regarded as due to a toxemia. For this reason he was referred for a cardiac examination.

May 14 he had a complete hemiplegia, apparently due to a cerebral embolism. The pulse was completely irregular. The rate varied from 50 to 130 per minute.

Examination showed right hemiplegia. The patient was unable to speak distinctly. He apparently was conscious of

his surroundings. The respirations were rapid, varying from 30 to 40 per minute. The lungs showed a dullness at both bases together with consonating rales. There was a moderate number of coarse rales throughout the chest. The heart was enlarged. The apex was 1 inch outside the midclavicular line. There was considerable enlargement to the left in the third and fourth interspaces. A soft systolic murmur was heard at the mitral area. The first sound at the mitral area was absent.

Fig. 2—Teleoroentgenogram of May 17, 1933 showing an enlarged right auricle and pulmonary conus. The pulmonary artery is very prominent. The left auricle is also moderately enlarged.

The second pulmonic sound was extremely accentuated and was also very definitely palpable.

May 23 there was an increased enlargement of the heart to the left. The systolic murmur at the mitral area was louder and longer, together with a definite diastolic rumble at the apex. The electrocardiogram on this date showed a slow fibrillation. The fourth lead (chest) showed a marked elevation of the ST interval (fig. 1).

A diagnosis of mitral stenosis, coronary occlusion and pulmonary infarcts was made.

The temperature was elevated from May 12 to May 27, averaging about 100.5 F. For two days, May 24 and 25, it reached 103.6 F. The pulse remained completely irregular. After complete digitalization the heart rate decreased. The first sound at the mitral area recurred and became accentuated. Following this the fever gradually subsided.

June 7, when he left the hospital, there were no rales in the chest and the temperature was normal. The paralysis had improved so that he had almost complete use of his leg and about 50 per cent use of his arm. Facial paralysis was also much improved.

Fig. 3—Mitral valve showing a markedly thickened and calcified posterior cusp and a fibrotic anterior cusp forming a semilunar slit between the free margin.

June 11 he had a short recurrence of acute pulmonary edema and rapid fibrillation. This attack completely subsided in five days. Then for several weeks he was quite comfortable in bed and sat up in a chair several times.

June 24 he had a recurrence of the acute respiratory distress. This gradually increased in intensity with extremely rapid respirations and rapid fibrillation. He died, June 30.

Results of the laboratory examination were as follows:

The urine showed specific gravity, 1.026 with acid reaction, albumin, trace, and sugar negative. Microscopic examination

of a specimen yielded a few white blood cells, and a few red blood cells.

Blood pressure readings were as follows: May 14, 1933, 80/60; May 18, 100/80; May 22, 100/60; and May 30, 90/50.

The blood count, May 13, was: hemoglobin, 94 per cent; red blood cells, 5,200,000; white blood cells, 14,200; polymorphonuclear leukocytes, 78 per cent; lymphocytes, 21 per cent; eosinophils, 1 per cent.

Cultures of the blood were negative. The blood Wassermann reaction was negative.

A teleroentgenogram (fig. 2) showed an enlargement of the right auricle and marked prominence of the pulmonary artery and the pulmonary conus. The left ventricle was also enlarged. The general contour was that of a mitral stenosis and an enlarged left auricle.

At autopsy the heart was markedly enlarged, especially the right side and the left auricle. Almost the entire anterior surface of the heart lay against the chest wall. The pericardium showed a large white superficial plaque, measuring about 2 by 3 cm on the anterior surface of the right ventricle. There was a slight roughening of the pericardium around the large vessels. The pericardial fluid was not increased.

When the right heart was opened there was extreme dilatation. The columnae carneae were extremely conspicuous. The papillary muscles were elongated and hypertrophied. The right auricle was markedly dilated. The tricuspid valve admitted four fingers. The pulmonary valve appeared normal. Both

Fig. 4—Relation of the calcified nodule in the myocardium and the left coronary artery which was obstructed. A: left coronary artery; B: calcified nodule.

of the latter showed no structural changes. The pulmonary artery was markedly enlarged, so that it abutted against the third costal cartilage, to which it was adherent. The wall was thickened at this point but otherwise appeared normal. The left auricle was widely dilated and hypertrophied. The left ventricle was moderately dilated and the myocardium was extremely flabby, soft and necrotic. It had a dark gray appearance. The fibers seemed to be partially separated. This involved the entire left ventricle with the exception of a strip 2 or 3 cm in width along the septum on the posterior surface. There were several large patches along the left side of the septum which presented the same appearance. The posterior cusp of the mitral valve was completely calcified (fig. 3), having a thickness of about 1 cm. The anterior cusp was markedly fibrotic with some calcified nodules. The mitral orifice formed a semilunar slit about 2 cm in length. The consistency of the valve cusps appeared not to permit opening of the valve during diastole.

The aortic valve showed some thickening and calcification. The sclerotic process involved about one half of the width. The cusps were not adherent to each other at their points of attachment. Apparently the valve could not close completely but nearly so. The aorta, except for a few soft yellow plaques, was smooth and elastic.

The orifice of the right coronary artery was patent and the wall was smooth and free from sclerosis and atheromas. The left coronary artery presented a patent orifice and its walls were also free from calcification and atheromas of any of the

larger branches. There was a calcified nodule (fig 4) about the size of a grain of wheat (2 mm by 1 mm) lying just at the upper margin of the left ventricle. This was placed with the long axis at about right angles to the ventricular wall. One end could be palpated just below the anterior cusp of the mitral valve slightly to the left of the juncture of its anterior and posterior cusps. The other end projected through the attenuated layer of the ventricular wall at the auriculoventricular junction so that it pressed against the left coronary artery and thereby obstructed it. At this point the intima of the left coronary artery was a deep red. This change was present throughout the larger branches. These vessels were empty and contained no blood. Apparently with dilatation and fibrillation sufficient pressure was exerted on the coronary artery to obstruct it completely. The clinical course would lead one to believe that earlier this obstruction may have been intermittent.

Microscopic examination of the myocardium of the left ventricle was as follows. The muscular fibers were separated and distinctly less compact. Fragmentation and degeneration of the fibers were conspicuous. This was not a simple lack of continuity due to fixation and cutting, but the loose ends showed poor staining qualities. The cytoplasm was granular or vacuolated. In some places the frayed edges bridged a gap in the muscle fibers. In other places one or several fibers showed a similar degenerative change along their course. Between some fibers there were several small areas of a cellular detritus and a few lymphocytes and polymorphonuclears, apparently the site of serous deposit. The endothelial layer of the larger arteries was largely desquamated and was partially covered with a hemorrhagic exudate.

Other autopsy changes consisted of infarcts of the lungs in various stages of degeneration and a chronic passive congestion of the liver and kidneys.

AN UNUSUAL OVARIAN TUMOR CONTAINING AN ESTROGENIC HORMONE

SAMUEL H. GEIST, M.D., AND FRANK SPIELMAN, M.D.,
NEW YORK

Löffler and Priesel¹ have described a group of six tumors which because of well defined morphologic characteristics, they concluded arose from cells in the ovarian stroma, representing the forerunners of the theca interna cells.

More recently Melnick and Kanter² reported two additional cases and suggested on hypothetical grounds that these tumors contained an estrogenic hormone.

These tumors occur most commonly in the postmenopause and are associated with atypical uterine bleeding. The latter symptom was believed to be due to the hormone activity of the tumor. In a later publication this tumor group will be more extensively discussed but at the present we report a case of this type the ninth case to be recorded and the first in which an estrogenic hormone was demonstrated in the actual tumor tissue.

REPORT OF CASE

Mrs. J. H., aged 21, had been married four years and never been pregnant. Her menstrual periods had begun at 11 and up to the age of 16 were regular and normal. From her 16th to her 17th year she bled daily. Since she was 17, up to a few months before admission she had bled every other week, the periods lasting from five to six days. For the past few months she had been bleeding almost daily and for the past four weeks had been amenorrheic.

The physical examination was negative except for the rather excessive breast development and the presence of a firm left

sided pelvic mass the size of a peach. A diagnosis of a solid ovarian tumor was made.

At operation a left salpingo-oophorectomy was done, removing an ovarian tumor, firm, irregular on its surface and about the size of a peach. The uterus was enlarged, soft and succulent. The other ovary seemed grossly normal. Unfortunately no endometrium was obtained.

Fig. 1—Gross tumor bisected, showing capsule, degenerative cystic areas and fibrous bundles in solid area to the left.

The tumor (fig. 1) weighed 68 Gm. and measured 7 by 4.5 by 6 cm. It was encapsulated and presented no defect in the capsule. A small simple cyst 1.5 cm. in diameter was present on the surface. The tumor was elastic in consistency and was a yellowish white.

Fig. 2—Connective tissue areas with few spindle cells and one cellular area (upper center about vessel).

On section it was seen to be composed of a firm yellowish gray tissue, lobulated and fibrous. The fibrous tissue septums radiated in all directions, dividing the tumor tissue into islands of varying size. There were numerous cystic areas distributed throughout the growth.

From the Gynecological Service and Laboratory Mount Sinai Hospital.
¹ Löffler, E., and Priesel, A. Beitr. z. path. Anat. u. z. allg. Path. 90: 199, 1932.
² Melnick, P. J., and Kanter, A. E. Am. J. Obst. & Gynec. 27: 41 (Jan.) 1934.

Histologically the tumor was composed of areas of hyalinized connective tissue (fig 2) that contained comparatively few cells. In some of the areas islands of large plump spindle cells (figs 2 and 3) were present and in others the cells were polygonal (fig 4). The nuclei were rounded or elongated, the cells having an epithelioid appearance. About the vessels there

Fig 3—Connective tissue areas with one cellular island

seemed to be a tendency for these cells to persist in large numbers. The cells in many instances contained varying sized vacuoles. Fat stains showed that the vacuoles were lipid material and

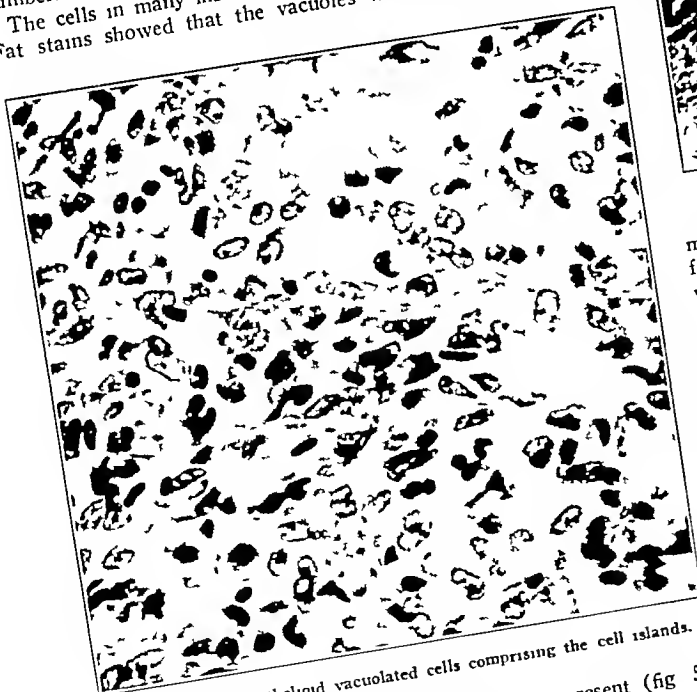

Fig 4—Large epithelioid vacuolated cells comprising the cell islands.

that even between the cells fat droplets were present (fig 5). The polariscopic examination identified much of this lipid material as double refractile, i. e., cholesterol. The gross appearance, the histologic characteristics and the presence of lipid were the same as described by the authors previously mentioned who concluded that these tumors were neoplasms arising from the precursors of the theca interna cells.

Thirty-two grams of this tumor was extracted with alcohol and ether. The extract was then taken up in oil and titrated for the presence of an estrogenic hormone. A positive reaction in the castrated mouse was obtained with 0.75 Gm of tumor tissue. It was thus found that in the 32 Gm extracted 48 mouse units of the hormone was present. This amount more than equals the quantity found in an equal weight of placenta. Associated with this excessive hormone content there was almost constant bleeding and breast hypertrophy.

The fluid from the cystic areas, which apparently represent a degenerative process in an amount up to 0.5 cc., did not contain a mouse unit of hormone.

It is evident that neoplasms may arise from the ovarian stroma of varying histologic appearance, which have the capacity of either storing or producing an estrogenic substance. The granulosa cell tumors form one group and the type here described designated by Löffler and Priesel as fibroxanthor thecocellular or as we prefer to call them theca cell tumor is another.

Following the operative removal of the tumor five months ago the patient has remained well. She had three nor-

Fig 5—Sudanophile granules and masses in and between the cells menstrual periods at twenty-eight day intervals and of from four to five days duration. The breasts have become somewhat smaller.

COMMENT

The presence of so large a quantity of estrogenic hormone within the tumor must lead to the conclusion that this was the factor directly associated with the excessive bleeding which the patient experienced. The prompt return to a normal period type after the removal further suggests a hormone influence. Likewise, the breast hypertrophy may be directly related to the excessive hormone content. As to the tumor itself, the histologic characteristics as well as the presence of lipid place it in the group described by Löffler and Priesel. It is evident that neoplasms giving varied histologic pictures and having the ability either to store or to produce an estrogenic hormone may arise from the ovarian stroma. The granulosa cell tumors which also produce the hormone form one group, and the type here described and called theca tumors forms another.

CONCLUSION

Investigations of the hormone activity of ovarian neoplasms has aided in producing a more definite classification of tumors of the ovary and has shed more light on the pathologic physiology involved.

ABDOMINAL PREGNANCY

REPORT OF A CASE WITH A FULL TERM LIVING INFANT AND RECOVERY OF THE MOTHER

J R EISMAN MD AND C F ZIEGLER MD PITTSBURGH

Although the occurrence of abdominal pregnancy is frequently reported, it is uncommon to note the birth of a full term living infant delivered from such a gestation. Only three proved cases of abdominal pregnancy have been found among 28,253 deliveries at the Elizabeth Steel Magee Hospital.

By a survey of the literature from 1809 to 1919, and questionnaires to 200 obstetricians, Beck¹ was able to collect only 262 cases of extra-uterine pregnancy after the fifth month with a living infant. Because of its exceptional nature, the case reported here is given in detail.

REPORT OF CASE

History.—M Y, a white woman aged 23, a secundigravida, referred to the service of Dr C E Ziegler at the Elizabeth Steel Magee Hospital by Dr W H Goodpastor Sept 5, 1933, had a spontaneous delivery of a full term baby seven years before. Otherwise her history was irrelevant. Her last normal period was Nov 28, 1932 and the estimated date of confinement, Sept 8, 1933. During her pregnancy she complained of some discomfort over the symphysis pubis and constipation but no history of pain, bleeding or other symptoms of tubal pregnancy or rupture could be elicited.

Physical Examination.—The patient was well developed and nourished and complained of no subjective symptoms or abdominal pain. Examination of the head, neck and chest revealed no pathologic lesions. Pelvic measurements were normal.

The fundus of the uterus was believed to be 25 cm in height. The fetus occupied an oblique position (right scapulo-

By rectal examination a mass was found which occupied the left side of the pelvic inlet. This was about 10 cm in diameter, solid, mobile and at first was believed to be an ovarian tumor or pedunculated uterine fibroid. There was no presenting part in the pelvis.

By vaginal examination, under anesthesia, this mass could not be felt but the posterior culdesac was filled by a semi-

Fig 2—Lateral view showing the relatively superficial position of the fetus. Fetal parts are not obscured by the normal quantity of amniotic fluid.

Fig 1—Fetus lying in the right scapulo-dorso-anterior position. Note absence of normal globular uterine shadow.

dorso-anterior) the fetal head lay in the right flank, small parts were easily palpated and fetal heart sounds were clearly heard in the lower right abdominal quadrant. External version was not completed owing to difficulty in dislodging the fetus and elevation of the fetal heart rate by the manipulation.

solid or cystic mass later proved to be placenta. The cervix uteri was long, soft and patulous, but because of impending cesarean section was not explored. Roentgenograms showed the fetus to be lying in a transverse position with the head to the right side and back anterior. The fetal parts were not obscured by the usual amniotic fluid. The rounded outline of the uterus was not visible.

The physical changes of a high transverse presentation of the fetus, superficial fetal parts and heart sounds and detected pelvic mass in conjunction with the roentgenograms led to the diagnosis of abdominal pregnancy. The patient was scheduled for laparotomy the following morning but that evening she complained of abdominal cramps and there was some vaginal bleeding. She was prepared for immediate operation.

Operation.—The vagina and abdomen were prepared with tincture of merthiolate. A midline suprapubic incision was made. The peritoneum was opened, with the escape of a large quantity of straw-colored fluid and a large mass believed on first sight to be the uterus was apparent. This, however, had the mottled greenish appearance of the fetal surface of a placenta. Throughout its wall were many fine interlacing blood vessels and through these the fetal parts could be seen.

On closer examination the intact uterus, comparable to that of a six weeks pregnancy, was detected lying behind the symphysis pubis. It was now clear that we were dealing with an abdominal pregnancy. Arising from the vicinity of the right uterine cornu and directed diagonally upward across the amniotic sac was a heavier, more muscular band, probably the thinned out right fallopian tube. The sac was not adherent to adjacent parts except in the right side of the pelvis, in the posterior culdesac and to the descending colon. The right ovary was not seen.

The sac was incised, with the escape of an almost imperceptible amount of amniotic fluid and very little bleeding. A living male infant weighing 7 pounds 2 ounces (3,232 Gm) was

Read before the Allegheny County Medical Society, April 17, 1934.

1. Beck, A. C. Treatment of Extra Uterine Pregnancy After the Fifth Month. J. A. M. A. 73: 962 (Sept. 27) 1919.

extracted by the breech and resuscitated with some difficulty. The membranes of the amniotic sac were extremely thick and tough. The placenta was greatly enlarged and of dumb-bell shape. The lower lobe to which the cord was attached was the larger and was firmly attached to the posterior surface of the uterus and broad ligament and to the right wall of the pelvis. The upper lobe, measuring 16 by 16 by 3 cm., was included in the posterior wall of the sac and had no attachment to any structure other than the remainder of the placenta, and to this by a narrow isthmus of placental tissue. Remnants of the umbilical cord and membranes were removed after clamping and double ligating with number 2 chromic catgut. The

Fig 3—Relative position of fetus, placenta and uterus. The upper portion of the placenta had no maternal attachment.

nonadherent upper lobe of the placenta was amputated after the pedicle was clamped and ligated with sewed in number 2 chromic sutures. The lower lobe of the placenta was undisturbed.

The peritoneum was closed with number 2 chromic catgut, without drainage. Muscle and fascial sutures were of chromic gut. The skin was closed with a plain catgut suture. The patient returned to the ward in good condition.

For two weeks, convalescence was uneventful. After this there was a gradual elevation of temperature, accompanied by definite fulness and extreme tenderness to the right of the incision. This condition was relieved by the evacuation of a large quantity of purulent exudate. Drainage from the wound continued for some days. Because of the placental tissue left within the abdomen it is of interest to know that the Aschheim-Zondek reaction was negative after eight days.

The baby, although at first lethargic, showed no abnormality other than a small hematoma of the left sternomastoid muscle. On discharge from the hospital it weighed 11 pounds 5 ounces (5,132 Gm). A roentgen examination of the injected uterus before discharge from the hospital, December 3, showed an irregular uterine cavity and iodized poppy-seed oil distributed about both sides of the pelvis. The left tube was outlined and was directed upward. Most of the iodized oil was collected in sinuses in the pelvis.

Pelvic examination, Jan 17, 1934, showed the uterus to be enlarged and mobile. The cervix was soft and patulous, and absorption of placenta and exudate has been so complete that no evidence of a pelvic inflammation or fulness could be detected in either side of the pelvis. Injection of the uterus with iodized poppy-seed oil is shown in figure 1.

CONCLUSION

The birth of a full time living infant and recovery of the mother after abdominal pregnancy is so rare as to justify reporting every case. Although this instance affords no evi-

dence of early tubal or ovarian implantation, to state that it was primary in type would be purely a conjecture.

Treatment of such a condition should include laparotomy, extraction of the fetus, removal of the membranes and cord after ligation, noninterference with the placenta, and, in the absence of infection, closure of the abdomen without drainage.

3708 Fifth Avenue.

GONORRHEAL TENOSYNOVITIS OF THE LONG HEAD OF THE BICEPS BRACHII

DIAGNOSIS MADE BY DEMONSTRATING GONOCOCCI IN THE TENDON SHEATH

ISADORE ZADEK, M.D. NEW YORK

This case illustrates a method of diagnosis that is seldom utilized, namely, the demonstration of organisms in the tissues. I have been unable to find a record of an identical case.

J. L., a woman, aged 22, admitted to the Hospital for Joint Diseases Feb 11, 1934, in the medical service, complained of pain in the left shoulder and chills and fever of twenty-four hours' duration.

She had typhoid at the age of 4 years. She had the usual diseases of childhood. She stated that she had never had syphilis or a gonorrheal infection.

The patient had been married one and a half years and was separated from her husband. She had had two abortions, one at three and a half months and another at five months. They were both spontaneous.

The night previous to admission, February 10, without any premonitory symptoms, she developed chills and fever, followed by pain in the left shoulder and both knees. These joints were not swollen but any attempt at motion was painful. There was no history of any previous joint involvement.

A section of the tendon sheath showing the inflammation and diplococci in the polymorphonuclear leukocytes.

When seen at the Hospital for Joint Diseases the patient complained of pain in the left shoulder. The left shoulder was swollen. Any attempt at motion caused excruciating pain. A greenish purulent vaginal discharge was present. Examinations of smears from this discharge were negative for gonococci.

The patient was treated by rest in bed and local applications and was given codeine and salicylates. There was no cardiac involvement and the case was considered to be an atypical arthritis.

The temperature on admission was 102 F. The next day it dropped to 98.6, February 15 it was 102.8. From February 18 to the 24th the temperature varied between 100 and 101.

The patient failed to improve and was transferred to the orthopedic service of Dr. Samuel Kleinberg February 15. At this time the left shoulder was diffusely swollen and was sensitive to pressure anteriorly. Anteroposterior motion of the shoulder was fairly free. Abduction and outward rotation were markedly limited and painful. The condition was considered to be an acute subdeltoid bursitis probably of gonorrheal origin. An attempt was made to aspirate the bursa but no fluid was obtained. A Velpert bandage was applied.

February 16 the left shoulder was stretched under anesthesia and a plaster of paris shoulder spica was applied with the shoulder in 70 degrees of abduction. The patient felt better but continued to have a fever.

February 12 the white blood cell count was 8000 with polymorphonuclear leukocytes 69 per cent. February 24 the white blood count was 12,800 with polymorphonuclear leukocytes 77 per cent. March 7 the white blood count was 6200 with polymorphonuclear leukocytes 65 per cent the temperature at this time being normal.

February 13 the blood Wassermann and gonorrheal complement fixation tests were negative.

February 26 the patient's temperature rose to 104 F. The shoulder spica was bivalved and removed. A roentgen examination showed an area of rarefaction in the greater tuberosity. It was questionable whether this was of any significance. On this day I explored the shoulder through an anterior incision 3 inches long. The tissues were all quite vascular. The greater tuberosity was explored by turning back a flap of bone with a mallet and chisel. The bone was normal. This flap was replaced and counter sunk. The distended sheath of the long head of the biceps tendon was opened for a distance of 2 inches. It contained a small amount of thin pus. The tendon was found frayed near the upper pole of the bicipital groove. The tendon was white and had lost its glistening appearance. The sheath throughout its exposed area was lined with granulation tissue. A culture of the pus was made and a portion of the sheath was sent to the laboratory for microscopic examination. The wound was packed with petrolatum gauze. The bivalved plaster-of-paris spica was replaced.

The patient's postoperative course was uneventful. She was given a transfusion, March 3, and discharged from the hospital March 21 wearing a plaster-of-paris shoulder spica.

The culture made at the time of operation was negative. The tendon sheath was reported to show granulation tissue infiltrated with various cellular elements.

The patient was followed in the outpatient department May 1. I examined the patient and reviewed her history. I was struck by our suspicions of this being a gonorrheal infection. All our examinations had been inconclusive. The laboratory had retained the tissue removed at operation. New sections were cut from the sheath of the tendon and a gram stain was made which showed numerous pus cells with intracellular gram negative biscuit shaped diplococci.

In brief, this was a case of gonorrheal tenosynovitis of the long head of the biceps brachii in which the diagnosis rested solely on the demonstration of the organisms in the substance of the tendon sheath.

1095 Park Avenue

Specialists in Ancient Times—It is likely that many skilful and sagacious medical men practiced in ancient Egypt where—Herodotus tells us—physicians were even more highly specialized than they are today since often they limited themselves to a single organ of the body. There were dentists as well as internists and surgeons. Hippocrates however is the first great physician from whom we have records and writings which show an approach to medical problems entirely analogous to our own. Indeed, his descriptions of cases in the *Epidemion* are so precise that diagnoses more accurate than the ones he made himself can be deduced from his clinical histories.—Zimsser Hans Rats Lice and History Boston Little, Brown & Co., 1935

GLANDULAR PHYSIOLOGY AND THERAPY

THE ADRENAL CORTEX

ROBERT F. LOEB, M.D.
NEW YORK

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed the series will be published in book form.—Ed

It has been known for many years that destruction of the adrenal glands in the human being, or complete ablation of these structures in most animal species, results in death. Following the isolation and synthesis of epinephrine, it was shown that this secretion of the adrenal medulla would not maintain life. In human beings suffering from severe Addison's disease, as well as in totally adrenalectomized animals, this hormone, regardless of the dose or means of administration, proved to have little if any therapeutic effect. In experimental animals extirpation of one adrenal and destruction of the medulla in the other led to no apparent deleterious effects, such animals survived indefinitely. Removal or destruction of both cortices, however, in the absence of sufficient accessory tissue, invariably caused death. Thus it was established that another substance present in the cortex of the adrenal gland was essential for life. Further proof of the validity of this idea was provided by the extraction of such a hormone and the demonstration that it would insure the survival of the adrenalectomized animal.

PREPARATION AND ASSAY OF CORTICAL HORMONE

In October 1927 Rogoff and Stewart¹ and Hartman² independently, published that they had produced extracts of the adrenal cortex which definitely prolonged the lives of adrenalectomized dogs and cats, though the former had reported their observations two years earlier. The method of Rogoff and Stewart consisted of extracting dogs' adrenals with 0.9 per cent salt solution and glycerin, these authors proposed the name "interrenalin" for the hormone of the adrenal cortex essential for life. Hartman's preparation, called "cortin," consisted of a saline extract of beef adrenals, from which most of the protein was removed by iso-electric precipitation.³ The average survival time of animals

³ Extracts of the adrenal cortex prepared by iso-electric precipitation as described by Hartman have been found by other workers to be practically or entirely inactive.^{1c} Subsequent publications by Hartman (*Proc. Soc. Exper. Biol. & Med.* 27:938 [June] 1930, 28:962 [June] 1931) concern extracts prepared by the use of certain lipid solvents (Hartman F. A. U. S. Patent 1914125 [June 13] 1933)—process patent for Cortin and Method of Preparing Same.—Ed

treated with these preparations was at least two and three times that of control animals.⁴ Pfiffner and Swingle⁵ in 1929 prepared an extract of the cortex of beef adrenal glands by means of organic solvents. This extract, injected in lipid form, extended the life of the adrenalectomized cat from an average duration of seven days to about thirty days,⁴ at which time the preparation caused severe irritation of the subcutaneous tissues. In recent years this method of preparation has been improved so that animals will survive for years with the administration of smaller amounts. In the last four years other methods of preparation of the cortical hormone have been developed, and recently Kendall⁶ has reported that he has isolated this substance in crystalline form.⁷ This preparation is believed to have a molecular weight of 350 and the empirical formula $C_{29}H_{30}O_6$. The observations of Kendall have not as yet been confirmed in other laboratories. It is not even certain at the present time that the active principle of extracts of cortical substance used experimentally represents a single chemical unit.

One other substance, vitamin C, was isolated in crystalline form in large amounts from the cortex of the adrenal glands by Szent-Györgyi⁸ in 1929. This compound has since been obtained from various other sources and its structure proved by synthesis. Originally it was designated "ascorbic acid", more recently the Council on Pharmacy and Chemistry has proposed the name "cevitamic acid". It is believed that the high concentration of vitamin C in the adrenal cortex may result from storage rather than from local synthesis, and its significance is still uncertain.

The problem of assaying the various preparations of the cortical hormone essential for life is of vital importance both for physiologic study and for clinical therapy. Unfortunately up to the present time only biologic methods can be employed. These have distinct limitations because of the wide individual variations among animals and also because of the great influence of physiologic and environmental factors such as the amount of sodium ingested, the amount of fluid administered or the type of diet employed, which may not be adequately controlled. A number of methods of assay have been suggested, most of these depending on the determination of changes in concentration of some constituents of the blood from a test animal. The cortical hormone has no demonstrable influence on the blood of a normal animal and therefore testing must

be carried out on those completely adrenalectomized. One method of assay consists in the determination of the amount of an extract necessary to prevent an increase of 100 per cent in the blood urea of an adrenalectomized dog in the course of from seven to ten days.⁹ The "dog unit" is defined as the minimum daily dose of an extract per kilogram of body weight necessary to prevent this increase in blood urea.¹⁰

Cortical extracts have usually been administered parenterally,¹¹ as it has been claimed that these are at least twelve times as efficient by this route as when given orally.⁹

FUNCTIONS OF THE CORTICAL HORMONE

There has been much speculation concerning the function of the adrenal cortex. Britton and Silvette¹ have postulated that "the adrenal cortex prepotently regulates carbohydrate metabolism."¹² Swingle and Pfiffner,¹² as well as others, have intimated that the primary function of the adrenal cortex is to regulate the circulating blood volume. In 1931 Swingle¹⁴ wrote "At the outset of this discussion the statement was made that the function of the adrenal cortex is a mystery. And so it is!" Careful clinical and physiologic studies of recent years have not solved the problem, but they suggest that more than one function exists.

Until the cortical hormone or hormones are definitely available in large amounts in crystalline form, the functions of the adrenal cortex will remain shrouded in mystery and confusion.

The study of the sequence of events occurring in human beings and in adrenalectomized animals during the development of acute adrenal insufficiency and subsequently following the administration of cortical extract or sodium chloride or both has, however, contributed a considerable amount of information.

Sodium Loss and Dehydration.—When the adrenal glands of an animal are removed, or when injections of cortical extract are withdrawn from an adrenalectomized dog, the complete picture of adrenal insufficiency develops in the course of a few days. The time relationships occurring in the development of a number of the physiologic disturbances are shown in the accompanying chart, prepared by Harrop.¹⁵ These changes and others to be enumerated may be correlated, wholly or in part, with the fact that the adrenal gland appears

4 The survival times of treated adrenalectomized animals reported by Stewart and Rogoff¹² considerably exceed the maximum (not only the average) for control animals in their own extensive series. However the average survival time of control adrenalectomized animals reported by Hartman¹³ was taken largely from the literature and hence may not properly be compared with the survival times for his treated animals. It should be noted that the survival times reported by different authors are not comparable, survival times of animals under treatment with cortical extract must be compared with those of untreated animals of the same investigator. Thus the longest periods of survival of untreated animals reported in the literature (those of Stewart and Rogoff) exceed in many cases the survival times of treated animals reported by other workers.—En

7 Crystalline products from extracts of the adrenal cortex have also been reported by other investigators notably by Wintersteiner and Pfiffner (*Proc. Soc. Biol. Chem.* April 10-13 1935 page c). However in view of the multiplicity of crystalline fractions reported both by Kendall and by Wintersteiner, and the apparent great variability in the claimed activity of the different fractions none of the crystalline products may as yet be considered to represent the life sustaining hormone of the adrenal cortex.—En

9 Pfiffner, J. J., Swingle, W. W. and Vars, H. M. The Cortical Hormone Requirement of the Adrenalectomized Dog with Special Reference to a Method of Assay. *J. Biol. Chem.* 104: 701 (March) 1934.

10 This is not an entirely satisfactory method of assay as several authors have pointed out. It appears that the only adequate criterion now available for the activity of adrenal cortical extracts consists in the property of prolonging the lives of completely adrenalectomized animals for a period well beyond the maximum survival time of control animals.—En

11 Extracts have been prepared that are active by mouth (Rogoff and Stewart¹²). Oral administration has the advantage of avoiding largely or entirely the toxic effects of contaminating substances such as have been reported following parenteral injection by Benham (Benham, H. W., Fisher, Mary and Thurgar, C. J. L. Three Cases of Addison's Disease Treated with an Extract of Suprarenal Cortex, *Lancet* 1: 125 [Jan. 16] 1932) and by Rowntree (Rowntree, L. G. and Ball, R. G. Diseases of the Suprarenal Glands, *Endocrinology* 17: 263 [May/June] 1933) in human beings and by Rogoff¹² in animals.—En

to exert a controlling influence on sodium metabolism.¹⁶ Early in the course of adrenal insufficiency the rate of sodium excretion through the kidney is increased and the concentration of this ion in the blood serum falls. Accompanying the decrease in sodium there is a decline in the concentration of chloride or bicarbonate or both. As sodium is lost from the body there is an increased, though not an equivalently increased, excretion of water. This progressive loss of salt and water leads to the depletion of the circulating fluid volume and of the fluid within the extracellular tissue spaces. The latter in turn leads to a further and critical decrease in blood volume, with the development of a state of shock.

The significance of the disturbance in sodium metabolism in the production of the picture of acute adrenal insufficiency is clearly seen in patients with outspoken Addison's disease. When no change other than the withdrawal of salt from the diet is instituted in the regimen of these patients, there results a characteristic chain of events. When adrenal insufficiency is established, the administration of salt may bring about improvement, just as the administration of cortical extract or salt does in the adrenalectomized animal.

The following changes may be ascribed to the loss of sodium with its accompanying dehydration: (1) decrease in concentration of sodium in the blood with a fall in blood bicarbonate or chloride or both, (2) increase in plasma protein concentration and in the oxygen capacity of the blood, (3) decrease in plasma volume, (4) decrease in rate of blood flow, (5) increase in excretion of chloride, (6) loss of weight. In turn, this resultant state of dehydration and shock is also probably of importance in augmenting the following manifestations of adrenal insufficiency: (7) refusal of food, (8) vomiting, (9) muscular weakness, (10) diminution in blood pressure, (11) diminution in metabolic rate,^{16a} (12) increase in total non-protein nitrogen of the blood and often in urea, and increase in phosphate and sulphate in advanced stages, and (13) anuria when shock is extreme.

Renal Function—In 1916 Marshall and Davis¹⁷ first demonstrated an increase in blood urea and a decrease in phenolsulphonphthalein excretion following total ablation of the adrenal glands. They suggested that

the secretion "of some substance by the adrenals which is necessary for the maintenance of normal renal function serves as a probable explanation" of the results obtained. Since that time it has been shown that the retention of total nonprotein nitrogen is an early and regular finding in adrenalectomized animals and that this abnormality is also usually encountered in the severe adrenal insufficiency of Addison's disease. Sulphate and phosphate retention also occur as the disorder progresses. It has been shown that at times urea retention occurs while the adrenalectomized animal is still clinically well, while the blood pressure is normal and while the urine volume is even greater than that present before any rise in blood urea occurs. Recent studies have shown that accompanying the increase in blood urea in the adrenalectomized dog whose dosage of cortical extract is reduced there is not only a decrease in phenolsulphonphthalein elimination but also a

Characteristic changes in metabolism, circulation and blood concentration in a group of adrenalectomized animals following withdrawal of extract.

decrease in urea clearance. These changes occur before there is any weakness, lassitude or anorexia and disappear with increasing doses of cortical extract. Thus it is apparent that the disturbances in renal function are dependent on cortical and not on medullary insufficiency. The decrease in renal function may be dependent on an influence of cortical substance on the kidneys directly, dehydration and shock augment the state of renal insufficiency.

The excessive loss of sodium from the body following lack of adequate cortical substance takes place through the kidney and in this sense may be termed a disturbance of renal function. It is of interest that sodium chloride administered orally to the adrenalectomized dog receiving inadequate doses of cortical substance improves renal function in that the blood urea falls and phenolsulphonphthalein excretion rises, as does the urea clearance. Lack of cortical substance causes the following evidences of alteration in renal function: (1) increase in blood urea, creatinine, phosphate and sulphate, (2) decrease in urea clearance, (3) decrease in excretion of phenolsulphonphthalein, and (4) increase in the excretion of sodium.

Potassium Excretion—Retention of potassium in the blood is a constant finding in adrenal insufficiency in animals and occurs in severe adrenal crises in human

16a It should be pointed out that the studies which indicate a diminution of basal metabolic rate in adrenalectomized animals were made on animals the survival times of which were very short. The significance of such a decrease in oxygen consumption of moribund animals is conjectural as no good measure of metabolic rate is said to occur during the period of relatively good health. See section on Oxygen Consumption.—Ed.

17 Marshall E. K. and Davis D. M. The Influence of the Adrenals on the Kidneys. *J. Pharmacol. & Exper. Therap.* 8: 525 (Sept.) 1916.

beings Whether this represents merely a manifestation of renal insufficiency or a more general disturbance of potassium exchange through the cell membranes of the body is not known It is conceivable that the increase in blood potassium or an alteration in the sodium-potassium ratio may contribute to the picture of collapse in an adrenal crisis

Carbohydrate Metabolism—Disturbances in carbohydrate metabolism have been recognized for many years as playing a prominent part in the syndrome resulting from total ablation of the adrenal glands In Addison's disease, too, abnormalities of carbohydrate behavior such as depression of the blood sugar and increased sensitivity to small doses of insulin have been observed Britton and Silvette¹² have studied this phase of adrenal insufficiency in various animal species They found a decrease in the sugar content of the blood and a decrease in glycogen stores, particularly in the liver They have reported that "emotion, excitement and [epinephrine] injection are practically without effect on the blood [sugar] of adrenalectomized cats tested at various time intervals after operation while the animals still appear in good health" Finally, they state that "with long-continued, twice daily, injections of [dextrose] during the period following adrenalectomy, there also occurs very little storage of glycogen in the liver" Despite this collection of evidence, doubt still exists as to whether these changes are not the result of medullary rather than of cortical deficiency¹⁸ This is particularly true because Britton¹⁹ and others have shown that increased sensitiveness to insulin exists in those animals in which the adrenal medulla has been destroyed without serious damage to the cortex Also, Harrop²⁰ has shown that increased sensitiveness to insulin persists in adrenalectomized dogs maintained by adequate doses of cortical extract Unfortunately, glycogen determinations on the livers of these animals are not available

The chief differences in carbohydrate disturbances between those animals with the medulla destroyed and those with the entire glands destroyed are found in the glycogen stores and the response to injection of epinephrine The former show no depletion of liver glycogen and give a hyperglycemic response when epinephrine is administered during the hypoglycemic state The latter, as previously stated, apparently have depleted glycogen stores and consequently are unable to exhibit as large an elevation of the blood sugar after injection of epinephrine²⁰

18 The concept that the adrenal cortex is especially concerned in the control of carbohydrate metabolism is based chiefly on the observation that adrenal cortical extracts were found to have a greater effect on blood sugar in adrenalectomized animals than the amounts of epinephrine these extracts were said to contain as determined by biologic assay (Britton S W and Silvette Herbert Effect of Cortico-Adrenal Extract on Carbohydrate Metabolism in Normal Animals *Am J Physiol* 100: 693 [May] 1932 The Apparent Prepotent Function of the Adrenal Glands *ibid*, page 701) However adequate attention appears not to have been paid to the possible effect of substances such as histamine (Clegg R A Observations on Extracts of Beef Adrenal Cortex and Elasmobranch Interrenal Body *J Physiol* 75: 413 [Aug] 1932) and choline (Eagle E Presence and Significance of Choline in Cortico-Adrenal Extract *Proc. Soc. Exper Biol & Med* 30: 1094 [May] 1933) which have been found in cortical extracts prepared by the Swingle Pfiffer method (which was the method employed by Britton and Silvette). These contaminants would render impossible accurate biologic assay of epinephrine In addition some of the observations appear to have been made on animals under the influence of ether or of amylal either of which may affect the blood sugar level The role of the adrenal cortex in the regulation of carbohydrate metabolism therefore remains undecided as Dr Loeb has indicated—Ed

19 Britton S W Geiling E M K and Calvary H O Medullary adrenal Secretion and Carbohydrate Metabolism, *Am J Physiol* 84: 141 (Feb) 1928 Harrop, G A and Weinstein Albert Studies on the Adrenal Cortex I Cortical Suprarenal Insufficiency and the Action of Cortical Hormone upon the Normal and Suprarenalectomized Dog *J Exper Med* 57: 305 (Feb) 1933

20 This subject is discussed further in the papers in this series by Rogoff (The Adrenal Medulla) and by Best (The Internal Secretion of the Pancreas)—Ed

Oxygen Consumption—It is well known that the basal metabolic rate of patients with severe Addison's disease and that of adrenalectomized animals showing signs of severe deficiency is decreased The mechanism of this change is not yet clear, but the fact that it does not occur in animals until about four days after withdrawal of cortical extract suggests that it may be secondary to other disturbances such as dehydration Fall in body temperature parallels the decrease in oxygen consumption and is possibly also dependent on the development of dehydration and shock^{16a} The sensitiveness to cold experienced by patients with relatively well "compensated" adrenal insufficiency cannot be explained at the present time

Adynamia—Muscular weakness and asthenia are probably the most important manifestations of adrenal insufficiency in man These symptoms may be present to a marked degree even though quantitative measurements of cortical insufficiency as determined by the blood urea, the blood sodium and hemoconcentration may be normal Whether this weakness results from cortical or medullary insufficiency is not certain, despite reports of improvement in patients following the administration of cortical extract On the other hand, it has been shown by Ingle that the capacity for sustained work in adrenalectomized rats is enormously enhanced by cortical extracts, and certainly the adrenalectomized dog receiving adequate doses of this substance shows no evidence of muscular weakness This evidence suggests but does not prove the importance of the adrenal cortex in maintaining muscle strength The underlying mechanism involved in the relationship between muscle weakness and the adrenal glands is not known It is clear that dehydration and shock serve only as contributing factors to weakness, because, as has already been stated, this symptom may be present to a marked degree without loss of base or urea retention Furthermore, strength increases strikingly in the adrenalectomized dog following the administration of cortical extract before obvious changes occur in the blood urea or sodium concentration or in the water content of the blood serum

Circulatory Collapse—The importance of salt loss and dehydration has already been stressed as being of significance in promoting the state of shock in adrenal insufficiency Swingle and his collaborators¹² have suggested that the absence of cortical substance produces a state of shock analogous to histamine shock in which capillary permeability is increased The decrease in blood volume under these conditions is supposed to be due to the flow of fluid into the tissue spaces The fact that salt and water are known to be lost from the body through the kidneys in large amounts would make the assumption of Swingle unnecessary²¹ In certain instances, however, the loss of base and water does not appear to be great enough to produce the profound peripheral circulatory collapse encountered Consequently the fact must still be borne in mind that adrenal cortical substance may exert some regulatory control of the vascular bed directly

Hypotension—Hypotension constitutes a regular finding in cortical insufficiency Its significance is not understood

21 The thesis of Swingle and his collaborators as to the rôle of the adrenal cortical hormone in circulatory shock has been further criticized on several grounds by Freeman (Science 77: 211 [Feb 24] 1933) Britton and Silvette (Science 77: 366 [April 14] 1933 footnote 12) and J McKeen Cattell (Science 77: 428 [May 5] 1933)—Ed

Pigmentation—The characteristic pigmentation of the skin and mucous membranes as it occurs in Addison's disease is not encountered in animals adequately treated with cortical extract or in a chronic state of adrenal insufficiency.

In a number of clinical reports on the effect of cortical extract in Addison's disease, it has been stated that the patients become lighter after treatment. This is true. However, in some of the cases observed the change appears to be due not to pigment loss but to rehydration of the tissue spaces with stretching of the skin. This idea receives support from the observation that within from two to five days following salt withdrawal in patients with Addison's disease, pigmentation appears intensified as acute adrenal insufficiency is induced. With the ingestion of salt and improvement pigmentation apparently becomes less intense. It is most unlikely that these rapid changes are dependent on deposition and solution of pigment.

Gastro-Intestinal Disturbances—Patients with compensated Addison's disease frequently have a hypochlorhydria, their appetites are capricious and they vomit with apparently very little cause. In adrenalectomized dogs and cats, bloody diarrhea may develop in the course of a few days after the withdrawal of cortical extract. However, there is nothing which need be considered specific of disturbed adrenal physiology in the anorexia, nausea and vomiting occurring in the collapse of severe adrenal insufficiency. The mechanism of these disturbances is not understood.

Neurologic Disturbances—Patients in severe adrenal insufficiency frequently show general or focal neurologic disorders including disorientation, confusion, aphasia, convulsions and reflex changes. In untreated adrenalectomized animals, spasticity and weakness of the hind legs are common and convulsions also occur. These disorders may at times be associated with hypoglycemic shock. This as has been intimated, may be referable to medullary insufficiency with the consequent loss of insulin antagonism. On the other hand, neurologic abnormalities may appear in the absence of severe hypoglycemia. These may result from decreased cerebral circulation, a part of the more general picture of dehydration and shock. There is no direct proof for the idea that changes in the central nervous system result from failure of any normal action of cortical substance on brain cells.

Immune Reactions—Much has been written concerning the role of the adrenal glands in immune reactions.²² The susceptibility of adrenalectomized animals to various bacterial toxins and to infections is among the aspects of the problem studied. The consensus suggests increased susceptibility to infection and intoxication in adrenal insufficiency. The chief difficulty in evaluating results obtained from this type of study seems to be in the fact that the subjects for investigation are sick animals, and, therefore, the specificity of adrenal deficiency becomes doubtful. Clinical observation of patients with Addison's disease does not indicate any particular susceptibility to infectious disease.

When infection develops in one of these patients, however, the severity of adrenal insufficiency is augmented.

Effects of Other Endocrine Glands—A study of the effect of cortical insufficiency on other endocrine functions in animals is difficult because prolonged severe insufficiency is incompatible with life.^{22a} It has already been indicated that up to the present time it has been found impossible to produce any detectable changes in the normal animal by the injection of cortical extract. Nature has, however, produced one experiment in which the products of the adrenal cortex appear to induce certain other endocrine disturbances. With certain tumors of the adrenal gland, hirsutism and amenorrhea develop with regularity, the relationship of these phenomena to basophilic adenoma of the pituitary has been discussed in the first paper in this series, by Evans.

Hartman²³ has recently reported evidence for the presence of a second hormone in the adrenal cortex, "cortilactin", this he considers to be absent from certain cortical extracts and to be essential for lactation in the adrenalectomized animal. Further investigation will be necessary to confirm these results.²⁴

As already indicated, until the cortical hormone or hormones are definitely available in sufficient quantities in crystalline form, the endocrinologic relationships as well as the other functions of the adrenal cortex will remain in a state of confusion.

THERAPEUTIC APPLICATION OF THE CORTICAL HORMONE

The development of cortical extracts has reached a stage at which it is possible to maintain totally adrenalectomized animals in apparently normal health. In this direction a great advance has been made which is encouraging for the future application to human disease.

Despite the earlier reports²⁵ concerning the use of cortical extracts in the treatment of Addison's disease, the ultimate goal has not been reached. On the basis of animal experimentation this failure in many cases appears to be largely dependent on the fact that the commercial preparations available may be too dilute or that they deteriorate, surely they are too costly to be administered in adequate amounts over long periods of time.

It seems certain that the administration of cortical extracts and of sodium chloride has a definitely beneficial effect in the acute crises of Addison's disease. It is also certain that, while salt alone will prolong life, it will not maintain it indefinitely in the adrenalecto-

^{22a} However chronic and subacute adrenal insufficiency may be produced in animals by subtotal ligation of the adrenals, as Rogoff has demonstrated (Proc. Soc. Exper. Biol. & Med. 29: 1240 [June] 1932). Animals with chronic insufficiency have been found to survive up to 14 months. The histologic changes in the adrenals characteristic of Addison's disease have been reproduced in all gradations in some cases infection was superposed on the ischemic glands. Thus a method is available for studying the effects of prolonged adrenal insufficiency both medullary and cortical.—En.

²³ Brownell, K. A., Lockwood, J. E., and Hartman, F. A. A Lactation Hormone of the Adrenal Cortex. Proc. Soc. Exper. Biol. & Med. 30: 783 (March) 1933.

²⁴ Recent investigators have suggested the presence of still other special hormones in the adrenal cortex. This is based on the finding that certain products (crystalline and noncrystalline) obtained from cortical extracts appear to have special effects in adrenalectomized animals apart from the life sustaining property.² However the present evidence is so conflicting and confusing that judgment must be reserved for the present.—En.

mized animal. A certain amount of cortical extract is essential. Hence it would seem logical that even small doses of cortical extract would be better than none. Nevertheless, in my limited experience, it has been impossible to demonstrate objective effects (on blood urea and blood sodium) of a commercial preparation of cortical extract given in daily doses up to 10 cc. Also, 25 cc given in one day in addition to salt and dextrose has failed to check progressive adrenal insufficiency. Whether the apparent effect on appetite and sense of well being is more than psychologic is uncertain. It is highly improbable, however, that doses of from 2 to 3 cc given two or three times a week have any significant physiologic effect. The recent studies of Rogoff²⁴ support this idea.

There is at the present time a tendency toward the widespread and indiscriminate administration of cortical extract in small and infrequent doses to all those who are "weary and heavy laden." While this type of therapy may or may not be harmless, it is neither specific nor critically applied.

DIPHTHERIA MORTALITY IN LARGE CITIES OF THE UNITED STATES IN 1934

TWELFTH ANNUAL REPORT

This report concerns the ninety-three cities dealt with in the recent article on typhoid,¹ and the rates are calculated on the basis of the population figures used in that article. The number of diphtheria deaths in each city has been reported to us by the respective health departments.² Particulars as to the years that are included in the five year averages annotated as "incomplete data" are given in footnotes to tables 1-8 in our previous reports through the one covering 1931 and are itemized at the beginning of the article for 1932.

In the New England cities (table 1) diphtheria continues to decline. In 1934 these fourteen cities had only forty-four deaths from diphtheria, as against seventy in 1933 and ninety-six in 1932. Cambridge, New Bedford, New Haven and Springfield completed the year without a single diphtheria death, and Hartford, Providence and Worcester state that the only deaths were in nonresidents. New Bedford's clear record comes after several years of rather high diphtheria mortality. Boston has the lowest rate in its history (1.1). Waterbury, after its sudden rise in 1933, had a low rate again in 1934, while Lynn and Somerville, after improvement for three years, had setbacks. Lowell's excessive diphtheria mortality of 1932 and 1933 continued in 1934, its rate having

been progressively higher each of these three years. Lowell's rate was the highest in the country in 1934 (150), it had been one of the ten highest also in 1932 and 1933. Somerville's 1934 rate (6.6) is also one of the ten highest (table 11). Lowell and Somerville are among the ten cities with highest 1930-1934 averages (table 10). Considering the recent five-year period the

improvement in diphtheria in the New England cities is striking (table 16). The group average for 1930-1934 is less than half of that for 1925-1929 (3.38 as compared with 8.34). Thirteen of the fourteen cities (Somerville being the exception, which seems to have had an epidemic in 1930) had lower averages for 1930-1934 than for the preceding quinquennium. In Waterbury the decrease is slight, and the New Haven average remains low (one of the lowest in the country—

1 Typhoid in the Large Cities of the United States in 1934. J. A. M. A. 104: 2093 (June 8) 1935.

2 It should be noted that the figures include all deaths of diphtheria that have occurred within the city limits of nonresidents as well as residents. In some instances this undoubtedly gives an exaggerated impression of the amount of diphtheria in a community but at present statisticians are agreed that the attempt to eliminate the deaths of nonresidents would often result in an understatement of the true mortality (Bureau of the Census Mortality Statistics, 1912, p. 13). Cities in which one third or more of the reported diphtheria deaths are stated to have occurred in nonresidents are indicated in tables 1-8. In 1934 there were twenty-five such cities in six of which there were no resident diphtheria deaths. A further discussion of the problem of the nonresident in diphtheria statistics was given in the report covering the year 1931.

table 10), while the Lowell average remains high. But in all the other cities the decrease between the two five-year averages is conspicuous, particularly for the four cities that were at the foot of the list for 1925-1929: the two rates for Bridgeport are 11.8 and 1.0, for Lynn 13.5 and 4.7, for Springfield 10.3 and 2.1, and for Fall River 12.0 and 3.9.

The cities of the Middle Atlantic states (table 2) had a slight increase in diphtheria mortality in 1934.

as compared with 1933, with 211 deaths as against 192 (table 16). Even so, its group rate is the lowest in the country (1.63). Eight of the eighteen cities had higher rates in 1934 than in 1933, but no striking increase appears, unless perhaps in Pittsburgh, where the rate is almost double that of the preceding year. Paterson, on the other hand, halved its 1933 rate in

1934. Despite the 1934 increase in this group of cities, the five-year averages tell a very cheerful story. Every single city has decidedly decreased its average annual rate in the past five-year period as compared with 1925-1929. While Camden is still at the foot of the list, as it was five years ago, and still has one of the ten highest five-year averages in the country (table 9), its 1930-1934 rate is 7.7, as compared with a 1925-1929 average of 21.9. Newark's rate declines from 14.5 to 3.0, Philadelphia's from 11.8 to 1.3, and Scranton's from 11.7 to 1.3. Syracuse, Yonkers and Rochester have among the ten lowest averages in the country (table 10). The group average for 1930-1934 is about a quarter of the corresponding rate for 1925-1929 (2.50 as against 9.97). The Middle Atlantic group had the next to the highest rate in the country for 1925-1929, for 1930-1934 it has the lowest. Moreover, this lowest group rate for 1930-1934 is only 40 per cent of the lowest rate for 1925-1929 (the Mountain and Pacific rate of 6.28).

The recent five-year average of the cities in the South Atlantic states (table 3) is less than half of their

average for 1925-1929 (3.54 and 7.37), and the five-year averages for seven of the nine cities in the group are likewise lower. The increases for Norfolk and Tampa are slight. Atlanta and Jacksonville, despite lowering their averages, had among the ten highest such rates in the country (table 11). The greatest improvement occurred in Baltimore, where the average declined from 7.6 to 1.7, and in Wilmington (from 10.9 to 5.3). Baltimore had the next to the worst rate in the group for 1925-1929, but its 1930-1934 rate not only leads the group but is one of the best rates among the thirteen cities in the country with more than 500,000 population. San Francisco (1.2) and Philadelphia (1.3) alone having better averages. For the year 1934 for the first time the group rate is below 3.0. Four cities had somewhat higher rates in 1934 than in the previous year, but Wilmington and Atlanta decidedly lowered their rates as compared with 1933, when the diphtheria mortality in both cities seems to have made a sudden rise.

The East North Central cities (table 4) had slightly more diphtheria mortality (eleven more deaths) in 1934 than in 1933, but no important change in rate in any of the individual cities. South Bend had its third successive year without a diphtheria death—a new record among American cities—and also the second-best five-year average in the group. We have no data for South Bend prior to 1930 with which to compare this average. All the other cities except Peoria had

lower averages for 1930-1934 than for the preceding quinquennium, remarkable reductions having occurred in the five cities that had the poorest 1925-1929 rates. Detroit (from 19.7 to 4.8), Cleveland (from 15.3 to 2.5), Chicago (from 11.7 to 4.3), Youngstown (from 10.5 to 3.3) and Milwaukee (from 8.5 to 2.0). The average for the group as a whole for 1930-1934 is less than one-third that for 1925-1929 (3.66 as compared with 11.21).

The cities of the East South Central states (table 5) are the only group in the country which does not show a brilliant lowering of rate in a comparison of the averages for 1925-1929 and 1930-1934. For this group the two averages are almost identical (6.34 and 6.36). Whereas their rate for 1925-1929 was the second best in the country (and practically the same as the best,

Incomplete data

which was 6.28, for the Mountain and Pacific group) their rate for 1930-1934 is the next to the worst (and virtually the same as the worst, which is 6.55, for the West South Central group). Four of the six cities have higher averages for 1930-1934 than for the preceding period, the largest increase being that for Knoxville (from 6.3 to 9.6), a city that has had one of the ten highest rates in the country for every year beginning with 1931. Birmingham and Nashville have lowered their averages, but still Nashville appears with Knoxville and Chattanooga among the cities with the ten highest (1930-1934) averages (table 9). Comparing the 1934 rates with those for 1933, we find a slight increase in the group rate (7.00), which is the highest in the country, as it was also in 1933 (6.84). Birmingham and Memphis are the only members of the group in which the 1934 rates are not higher than those for 1933. The other four cities had high rates in 1933 and higher in 1934 and hold second, third, fifth and sixth places on the list of ten cities with the highest 1934 rates in the country (table 11).

The cities of the West North Central states (table 6) had a few more diphtheria deaths in 1934 than in 1933, and three of the nine cities had higher rates. Duluth, however, had its second successive year without a diphtheria death the fourth such year in its history. In five-year averages, Wichita is the only city in the group which did not have a lower rate for 1930-1934 than

for the preceding period. The improvement is most conspicuous in Minneapolis, which had the highest 1925-1929 average in the group (11.9), double that of its twin city, St. Paul, the 1930-1934 rate for Minneapolis (1.7) is exactly one-seventh its preceding average and only a trifle higher than the corresponding rate for St. Paul. St. Louis has likewise shown great improvement, its 1930-1934 average being 4.3 as compared with a 1925-1929 average of 10.3. Duluth, for both periods, has one of the best national records (rates of 2.0 and 0.4, table 10). The group rate for the past five years is less than half of the rate for the preceding period and is the third best in the country.

The West South Central cities (table 7) considerably bettered their five-year average in 1930-1934, reducing it from 9.24 to 6.55, but this was a modest improvement compared with the halving and quartering done by six of the other groups, and the West South Central rate for 1930-1934 is the highest group rate in the country. El Paso is the only city in the group with a higher average for 1930-1934 than for 1925-1929, although the two averages for Dallas are practically the same (9.7 and 9.8). For the year 1934 there were 26 fewer diphtheria deaths in this group than in 1933, and notably lower rates are found for Fort Worth, Dallas and San Antonio. Three of the eight cities reported increased rates for 1934, the largest increase being for New Orleans (from 2.7 to 6.8). El Paso and New Orleans have among the ten highest 1934 rates in the country (table 11), and Dallas, El Paso, Fort Worth and Tulsa appear on the list of the ten cities with the highest 1930-1934 averages (table 9).

Four of the Mountain and Pacific cities (table 8) report no diphtheria deaths in 1934. For Salt Lake City, Seattle and Spokane this means two successive

years without a death from diphtheria, while Long Beach had only one death (and that in a nonresident) during the same period. San Francisco and Tacoma had only one diphtheria death each in 1934, in both instances in a nonresident. Seven of the eleven cities have 1934 rates below 1.0. Oakland and Denver are the only cities in the group showing an increase in 1934 as compared with 1933. The 1934 group rate is lower than the rate for 1933 (1.74 and 1.99). The group rate for 1930-1934 is less than half of the correspond-

ing rate for 1925-1929, and the 1930-1934 average for every one of the eleven cities is likewise lower than its preceding five-year rate. A striking reduction is that of Salt Lake City (from 101 to 03), other notable decreases occurred in Spokane, Tacoma, Portland and Denver. Four of the ten cities with best 1930-1934 averages in the country are found in this group. Salt

Baltimore Cincinnati	Hartford Jersey City	New York Philadelphia
-------------------------	-------------------------	--------------------------

* These are the same cities that were on the corresponding list in 1929 except for Camden. When the rates for Camden for 1925-1929 were recalculated in 1930 on the basis of the 1930 census, the 1925-1929 rate became larger than the one for 1920-1924. Camden therefore, did not really decline in this list in 1929.

1930-1934	93	0	0	0	24	69	0

Lake City, Seattle, Spokane and Long Beach (table 10). The group rate (2.69) for 1930-1934 is a close second to the Middle Atlantic rate (2.50), which is the best in the country.

To summarize the diphtheria experience of the ninety-three cities during the past five years. The East South Central group (table 5) had a 1930-1934 rate about the same as its rate for 1925-1929 (table 16), while the other seven groups showed remarkable decreases, their 1930-1934 averages being the following fractions of those for the preceding period: 25 per cent (Middle Atlantic), 33 per cent (East North Central), 41 per cent (New England and West North Central), 43 per cent (Mountain and Pacific), 48 per cent (South Atlantic) and 61 per cent (West South Central). Six of the eight geographic divisions had low 1930-1934 averages, ranging from 2.50 for the Middle Atlantic cities to 3.66 for those of the East North Central states, the East South Central and West South Central averages were 6.36 and 6.55 respectively.

All the cities had 1930-1934 averages below 10.0, and sixty-nine had rates below 5.0 (table 14). Ten cities (not counting South Bend, for which data are lacking) had higher rates for 1930-1934 than for 1925-1929, but in only the following three did the amount of increase exceed 1.0: Somerville, Knoxville, Louisville. Of the

ten cities with highest 1930-1934 averages (table 9), four were in the West South Central states, three in the East South Central, two in New England and one in the Middle Atlantic group. Whereas the lowest 1925-1929 average was 1.4, there were ten rates for 1930-1934 that were below 1.0 (table 10), occurring in the following groups of cities: four in the Mountain and Pacific group, three in the Middle Atlantic cities and one each in New England, the East North Central and West North Central groups. Five of the ten cities with lowest rates for 1930-1934 were on the corresponding list for 1925-1929 (Duluth, Grand Rapids, New Haven, Seattle and Syracuse).

Apparently the tremendous improvement in diphtheria in the large cities, indicated by the comparison of the 1925-1929 and the 1930-1934 averages, became established before 1934. In any case, for the country as a whole the year 1934 had only forty fewer diphtheria deaths than 1933 (table 15), whereas, beginning with 1928 up through 1933, the annual diminution had ranged from 175 to 911 deaths. In 1934 four of the geographic sections had slightly increased rates and the other four had decreases, the decreases for New

TABLE 15—Total Diphtheria Death Rates for Eighty-Eight Cities, 1923-1934*

* Lacks data for 1925 for Jacksonville and Miami.

† Lacks data for South Bend.

‡ Lacks data for Oklahoma City for 1925 and 1926.

England and the West South Central cities being fairly large. Among the ten highest 1934 rates (table 11) are represented two New England cities, two South Atlantic, two West South Central and four East South Central. Of the fifteen cities without a single diphtheria death in 1934, four are in New England, four in the Mountain and Pacific states, three from both the Middle Atlantic and East North Central groups, and one from the West North Central cities. Eight-of

these fifteen cities also had clear records in 1933, for only four cities was 1934 the first year without a death from diphtheria

It is striking that the East South Central cities seem to have shared less than the other geographic divisions in the great reduction in diphtheria mortality in the last five years. In this connection it may be mentioned that a recent study³ of diphtheria mortality in the white and Negro populations in various American cities indicates that Negroes have a lower mortality from diphtheria than does the white population. From the experience of the other groups of cities dealt with in the present article, diphtheria is proving itself amenable to control measures

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER Secretary

VICTOR ELECTROSURGICAL MACHINE ACCEPTABLE

Manufacturer General Electric X-Ray Corporation, Chicago

This device is recommended for electrosurgery only. It is constructed similarly to the other Victor machines. The spark gaps, transformer, 60 cycle reactance and condensers are of the same construction as in other machines. The construction of the mounting and the insulation are satisfactory. A single switch throws the connections from "scalpel" to "coagulation". The switch mounting is firm.

At various loads this unit was tested to determine the power efficiency and frequency. The frequency varies with the variometer setting, staying, however, within a 400 to 1,000 kilocycle per second range. The frequencies are well above neuromuscular response. The efficiency varies from 8 to 30 per cent, depending on the conditions. The high frequency power generated varies from

Fig 1—Victor Electrosurgical Machine.

46 to 177 watts for the "scalpel" connection and from 15 to 90 watts for "coagulation"

Fig 2—Circuit of Victor Electrosurgical Machine

In a clinic acceptable to the Council this unit has been tried out under practical conditions in surgery and has been found to come up to expectation.

In view of the foregoing, the Council voted to include the Victor Electrosurgical Machine in its list of acceptable devices

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

DEXTROSE (See New and Nonofficial Remedies, 1935, p 280)

The several accepted solutions of dextrose and dextrose in physiologic solution of sodium chloride (The Cutter Laboratory) marketed in 1 000 cc. size Saftiflasks are also supplied in 500 cc. size Saftiflasks

DEXTROSE (See New and Nonofficial Remedies, 1935, p 280)

The Cutter Laboratory, Berkeley, Calif

The following dosage forms have been accepted

Solution Dextrose U S P 2½% in Physiologic Solution of Sodium Chloride in Saftiflask Container. Each Saftiflask contains 1 000 cc. of a solution containing dextrose U S P 26.25 Gm and sodium chloride, 8.5 Gm

Solution Dextrose U S P 5% in Physiologic Solution of Sodium Chloride in Saftiflask Container. Each Saftiflask contains 1 000 cc. of a solution containing dextrose U S P 52.5 Gm and sodium chloride 8.5 Gm

Solution Dextrose U S P 10% in Physiologic Solution of Sodium Chloride in Saftiflask Container. Each Saftiflask contains 1 000 cc. of a solution containing dextrose U S P 105 Gm and sodium chloride 8.5 Gm

Solution Dextrose U S P 20% in Fractionally Distilled Water in Saftiflask Container. Each Saftiflask contains 1 000 cc. of a solution containing dextrose U S P 210 Gm

Solution Dextrose U S P 25% in Fractionally Distilled Water in Saftiflask Container. Each Saftiflask contains 1 000 cc. of a solution containing dextrose U S P 262.5 Gm

SKIODAN (See New and Nonofficial Remedies, 1935, p 254)

The following dosage form has been accepted
Tablets Skiodan 1 Gm

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT

PAUL NICHOLAS LEECH Secretary

THIOGLYCEROL SOLUTION 1 50 (ABBOTT)

In this issue of THE JOURNAL there is an article by Dr Leon E Sutton on "Thioglycerol—A More Stable Sulphydryl Compound for Use in the Healing of Wounds." At the suggestion of the author, the Abbott Laboratories presented Thioglycerol Solution 1 50 to the Council so that its present status could be reported concurrently with the article.

Thioglycerol Solution 1 50 is one part alpha mono-thioglycerol ($\text{CH}_2\text{OHCHOHCH}_2\text{SH}$) in fifty parts by volume of glycerol

Dr Sutton's article is apparently the first additional report on the use of sulphydryl compounds in the healing of wounds since the publication of an article on cysteine hydrochloride (Brunsting, L. A., and Simonsen, Daisy G. Cutaneous Ulcers Treated by the Sulphydryl Containing Amino Acid Cysteine. THE JOURNAL, Dec 16, 1933, p 1937). Subsequently the Council issued a preliminary report on cysteine hydrochloride (THE JOURNAL, March 24, 1934, p 929), which declared the available evidence insufficient.

It is claimed that thioglycerol is more stable (less readily changed chemically and hence less readily rendered inactive) than its predecessors thioglucose, which stimulated bacterial growth as well as cell proliferation, thiophenol thioresol, which permitted an exuberance of granulation tissue (Reimann S. P. Use and Reasons for the Use of Thiocresol to Stimulate Wound Healing. THE JOURNAL, May 3, 1930, p 1369), and cysteine hydrochloride. Thioglycerol Solution 1 50 has a hydrogen sulphide odor, which is avoided with cysteine hydrochloride, but retains an advantage over thioresol in that it counteracts the formation of excessive granulation tissue.

One part of Thio glycerol Solution 1 50 diluted with 100 parts by volume of glycerin U S P or an aqueous glycerin solution containing 70 per cent glycerin or water is submitted for use in the treatment of sluggish wounds such as those due to burns and in bed sores and other slow healing wounds. This product is definitely contraindicated by the nature of its action in any wound in which there is possibility of neoplasm. Dr Sutton reports satisfactory healing in all but sixteen of 208 cases treated. Thio glycerol has replaced cysteine hydrochloride at the clinic reporting most of the work with the latter product.

In the opinion of the Council further studies should be made on the stability of thio glycerol under usual ordinary pharmaceutical and clinical conditions, further investigations are also needed to determine more accurately its scope of usefulness and its stimulating action of epithelial proliferation while inhibiting excessive granulations. The Council, therefore, decided to postpone further consideration of Thio glycerol Solution 1 50 until this additional evidence becomes available.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

TREESWEET PURE CALIFORNIA ORANGE JUICE

Manufacturer—TreeSweet Products Company, Los Angeles

Description—Heated California Valencia orange juice practically equivalent to fresh orange juice in vitamin C content.

Manufacture—Selected tree ripened fruit, from orchards not sprayed with arsenical sprays, is washed between brushes, dried, inspected, automatically cut in halves and reamed by hand against revolving burrs. The juice is strained, rapidly heated to such temperature as will insure keeping qualities and avoid unnecessary loss of natural flavor, automatically canned while hot, sealed under vacuum and immediately cooled. Stainless steel tubing is used exclusively throughout the plant.

Analysis (submitted by manufacturer) —

	per cent
Moisture	85.9
Total solids	14.1
Ash	0.4
Fat (ether extract)	0.1
Protein (N X 6.25)	1.1
Reducing sugars as invert sugar	5.6
Sucrose (copper reduction method)	4.8
Crude fiber	0.02
Carbohydrates other than crude fiber (by difference)	11.5
Titratable acidity as citric acid	1.0

Calories—0.6 per gram 17 per ounce

Vitamins—Biologic tests show that this canned orange juice is equivalent in vitamin C content to freshly extracted orange juice.

Claims of Manufacturer—Retains practically all the nutritional values of natural orange juice. For all dietary and table uses.

CELLU BARTLETT PEARS PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House Inc., Chicago

Packer—Eugene Fruit Growers Association, Eugene, Ore.

Description—Canned cooked Bartlett pear halves packed in water without added sugar or salt.

Manufacture—The method of manufacture is essentially the same as for Cellu Juice-Pak Bartlett Pears (THE JOURNAL,

Aug 4, 1934, page 341), with the exception that the fruit is packed in water.

Analysis (submitted by distributor) —

	per cent
Moisture	92.1
Total solids	7.9
Ash	0.2
Fat (ether extract)	0.2
Protein (N X 6.25)	0.3
Reducing sugars as invert sugar	4.3
Sucrose	0.6
Crude fiber	1.1
Carbohydrates other than crude fiber (by difference)	6.1

Calories—0.3 per gram, 9 per ounce

Claims of Distributor—For diets in which sweetened fruit is proscribed.

SUNSHINE BRAND EVAPORATED MILK

Manufacturer—The Defiance Milk Products Company, Defiance Ohio

Description—Unsweetened, sterilized evaporated milk. The composition and procedure of evaporation and canning are essentially the same as for the usual evaporated milk (THE JOURNAL, April 16, 1932, p 1376).

CELLU APRICOTS PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Hunt Brothers Packing Company, San Francisco

Description—Canned cooked halved and stoned apricots packed in water without added sugar or salt.

Manufacture—The method of manufacture is essentially the same as for Cellu Juice-Pak Apricots (THE JOURNAL, Sept. 8, 1934 page 755), with the exception that the fruit is packed in water.

Analysis (submitted by distributor) —

	per cent
Moisture	91.7

Calories—0.3 per gram 9 per ounce

Claims of Distributor—For diets in which sweetened fruit is proscribed.

HEINZ STRAINED CEREAL

Manufacturer—H J Heinz Company, Pittsburgh

Description—Strained cooked wheat embryo, farina, cracked whole wheat and rolled oats.

Manufacture—Equal weights of wheat embryo, wheat middlings (farina), cracked whole wheat and rolled oats are cooked in water at atmospheric pressure, strained in an atmosphere of steam to remove all coarse particles, adjusted to a definite moisture content, vacuumized to remove air, filled into lacquer-lined cans, sealed under "vacuum" and processed.

Analysis (submitted by manufacturer) —

	per cent
Moisture	88.4
Total solids	11.6
Ash	0.3
Fat (ether extraction method)	1.0
Protein (N X 6.25)	2.9
Reducing sugars as invert sugar	0.7
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	7.2
Calcium (Ca)	0.01
Phosphorus (P)	0.07
Iron (Fe)	0.0005

Calories—0.5 per gram 14 per ounce

Micro-Organisms—Bacteriologic and incubation tests show the product to be sterile.

Vitamins—Vitamin biologic assay shows

13 Sherman units of vitamin B per ounce

7 Sherman Bourquin units of vitamin G per ounce

Claims of Manufacturer—Specially intended for infants, children, convalescents and special diets. Only warming is required for serving.

SATURDAY, JUNE 15, 1935

THE ORIGIN OF SYPHILIS

Still somewhat shrouded in obscurity, the origin of syphilis continues to be of historical and epidemiologic interest. The chief difficulties in securing an adequate solution seem to be inadequate evidence. The favorite theory has been that Columbus's men brought syphilis to Europe from Hispaniola (Haiti). The usual narration affirms that a new disease appeared at the end of the fifteenth century and spread over Europe. The physicians of the period were undecided as to the nature and cause of this extraordinary malady. Some considered it an epidemic disease caused by severe floods, which had occurred in the time of Alexander VI. Others thought that the disease was caused by a malign influence of the stars. Another and more commonly accepted theory, which was based on the accounts of Fallopius, de la Martiniere, Jacobus Carpus and Oviedo, states that the disease began at the time when Charles VIII, king of France, invaded Italy. When he attacked Naples, at that time guarded by Spanish troops, the latter were already infected through Columbus's returned voyageurs. The disease then spread to the invading French army. When the latter broke up and scattered, the disease attained epidemic proportions all over Europe.

Among modern historians, Iwan Bloch¹ has been the most important advocate for the American origin of syphilis, even to the extent of naming it the American disease. Previously it had been called the French disease, the disease of Naples, the Spanish pox or the Persian fire. Pusey² also is convinced that the preponderance of evidence for the American origin is overwhelming. Both the occidental and the oriental literature of antiquity contain descriptions of local genital diseases, but according to Pusey there seems to be no description of the syphilitic syndrome prior to 1493. The spread of syphilis can be traced in the local chronicles of the time. In 1495 it appeared in France, Germany and Switzerland, in 1496 in Holland and

Greece, in 1497 in England and Scotland and in 1499 in Hungary and Russia. Pusey further cites the entire absence of syphilitic bones of pre-Columbian origin in Europe as conclusive evidence of the absence of syphilis in Europe in pre-Columbian times. Virchow said that there was no reliable evidence of syphilitic bones on the European continent. These have been the most widely accepted views.

However, a minority has held opposed views. Gaston Vorberg³ maintains that the disease did not appear for the first time in Europe at the end of the fifteenth century but was present in Europe before the discovery of America. He finds the explanations of Diaz de Isla and Oviedo untenable. Their fable as to the American origin appeared twenty-five years after the return from Haiti and appeared at the same time as the use of guaiac as a remedy. As evidence of the existence of pre-Columbian syphilis in Europe he presents a Neolithic humerus and ulna found in the Valley of Petit Morin, which are apparently typical specimens of gummatous osteomyelitis. He further mentions the opinion of Ales Hrdlička of the Smithsonian Institution, who after examining thousands of bones decided that there was no trustworthy evidence as to the existence of pre-Columbian syphilis in America. He also emphasizes the extreme susceptibility of the native Indians to the syphilitic infection as contracted from their European conquerors. As a significant historical point, Vorberg points out that none of Columbus's contemporary enemies accused him of having introduced the pestilence. Even Diego Alvarez Chanca, the physician on Columbus's second voyage, is silent about it. R. C. Holcomb⁴ in a recent study expresses his skepticism as to the American origin of syphilis. He ascribes the sudden interest in syphilis at the end of the fifteenth century to several factors. One important influence was the European development of the art of printing and the consequent dissemination of knowledge. Another factor was the rise of the surgeon in public esteem. In those days the cultured, scholarly physician did not treat wounds and ulcers, these were left to the lowly barber and wound surgeon. Another difficulty was the confused state of ancient dermatology, which was finally evolving some definite disease entities out of the general hodgepodge. This applies particularly to leprosy, which was a broad term covering a multitude of dermatologic misconceptions. Holcomb cites the old surgeon Michael Angelus Blondus (1542), who believed in the great European antiquity of syphilis and identified it with disease described by Celsus and Paul of Aegina. C. S. Butler,⁵ in an amusingly vigorous polemic on the question of the American origin of syphilis, accuses Bloch of slurring over many

names of those who wrote concerning it from 1493 and selecting those who favor his views. He further points out that the Romans must necessarily have had syphilis because several of their surgeons, particularly Antyllus, a contemporary of Galen, developed a technique for the cure of aneurysm which held the field until John Hunter's operation was adopted about 1786. Aëtius of Amida in the sixth century A. D. also gave a perfectly good description of aortic aneurysm. Butler has studied Dürer's famous engraving "The First Syphilitic" and emphasizes the importance of the date (1484). He has critically analyzed the book of Ruiz Diaz de Isla and concludes that this author's material has little value in the discussion of the American origin of syphilis. In another recent study, Butler⁶ maintains that Aurelius Cornelius Celsus described a type of genital sore that could have meant only the chancre. Though Celsus did not know it was the initial lesion of a constitutional disease, he did know that it was different from another common ulcer of the genitals, which he also describes. Capper⁷ declares that the so-called lepers of Biblical times, who were cured in from seven to fourteen days, as well as the lepers of the Middle Ages, were in reality persons with the primary or secondary manifestations of syphilis. He maintains that syphilis among the Romans was described by Celsus, Aretaeus and Aëtius. In these descriptions one recognizes not only chancre and secondary syphilitic lesions but also tertiary manifestations of syphilis, including severe bone pains. Capper believes that syphilis did not exist in America before Columbus's arrival. The epidemic that was raging in Europe following the return of Columbus was due either to some disease or diseases other than syphilis or to syphilis plus the other diseases. Syphilis, however, played a minor part in the ravages resulting from the epidemic.

Another interesting question in the origin of syphilis, which has been neglected, concerns not so much the place as the mode of origin. When the first man came in contact with the first spirochete, a great biologic drama had its origin. Ashmead⁸ has called attention to the work of David Forbes of the British Anthropological Society, who wrote that there was a disease of llamas identical with syphilis in man. The bones showed caries, osteitis and periostitis. This disease in llamas was curable by mercurial therapy. Forbes has maintained that syphilis arose in the highlands of Peru among the Indian pack drivers, who were accustomed to unnatural sex relations with llamas. In fact, this unnatural habit was so prevalent in ancient times that a law was evoked which forbade unmarried men to own llamas, and married herdsmen were obliged to bring their wives along. Ancient Peruvian pottery

also gives evidence of these bestial practices. Ashmead has suggested that syphilis in the llama might be a variant as is cowpox in the cow. This disease in llamas might profitably be studied by modern investigators, as the question has apparently been forgotten since the contributions of Forbes and of Ashmead.

The available evidence on the origin of syphilis is thus fragmentary and inadequate. The data afforded by the bone remains are doubtful, since these are frequently of uncertain date and have been altered by exposure to erosion. The historical epidemiology of the disease indicates no definite reference to the syphilitic syndrome as such until the last four years of the fifteenth century. This does not necessarily signify that syphilis first appeared in Europe at that time. What it really demonstrates is the important fact that intelligent observers at that time first became aware that there was a disease of venereal origin which began with a local genital lesion and later evolved into a constitutional infection. It seems rational to suppose that the general cutaneous manifestations had passed unrecognized in the general muddle of dermatologic concepts prevalent at the time (leprosy, mentagra, saphati, scabies, gorre). In modern times Ricord distinguished between gonorrhea and syphilis, which up to that time had been frequently considered as various manifestations of the same disease. It would be equally irrational to state that in Ricord's time two venereal diseases had originated. Similarly illogical would be a theory that tuberculosis had its origin at the time Robert Koch discovered the tubercle bacillus, although the disease was vaguely known for centuries as phthisis, the wasting disease, scrofula, and so on. The confusion has been aided considerably by the multiplicity of names given the disease.

NONCARDIAC EDEMA

Information concerning the chemical changes associated with the development of edema is being rapidly accumulated. These changes vary with the etiologic factors involved. In the extrarenal edema of nephrosis, for example, which Leiter¹ reviewed a few years ago, several facts seem well established. Leiter summarized these "aphorisms" as follows: 1. All cases of active nephrosis present a significant proteinuria. 2. During the active stage, all cases of nephrotic edema present low total plasma proteins or low plasma albumin, and hence all present low protein osmotic pressure. 3. Nephrotic edema may disappear spontaneously or be absent in spite of albuminuria and low plasma proteins when the albumin-globulin ratio is high enough to give an osmotic pressure of the serum proteins above 20 cm of water. 4. Nephrotic edema is more likely to yield to various diuretic measures when the plasma albumin is above than when it is below about 2 Gm per hundred

1 Leiter Louis. Nephrosis. *Medicine* 10: 135 (May) 1931.

cubic centimeters 5 Nephrotic edema rarely persists any length of time after albuminuria has decreased markedly 6 The edema fluid in nephrosis, like that in "war edema" and experimental protein depletion, is a low protein filtrate of the plasma not involving the permeability of the capillaries in any way 7 Low plasma proteins are in themselves capable of accounting for the chronicity of nephrotic edema on a purely mechanical basis 8 Low plasma proteins and low protein osmotic pressure are certainly not the only factors in nephrotic edema but are probably the most significant

The experimental edema of proteinemia, whether produced by plasmapheresis or by diet, would seem to present many similarities to the edema of nephrosis. It is therefore especially interesting to examine two recent studies on experimental edema produced in these ways

Kirk's² investigations on dogs were undertaken to reveal the chemical changes accompanying edema formation resulting from lowering the serum proteins, especially the albumin fraction. Plasmapheresis was the method adopted to produce low proteinemia. The dogs were bled at intervals for periods varying from eleven to nineteen days, and the total amounts of blood removed varied from 6,620 to 10,090 cc. By this means a definite low proteinemia was produced in the dogs. Inversion of the albumin-globulin ratio did not occur. The regeneration of the serum globulin occurred at a greater rate than that of the albumin fraction after plasmapheresis was ended. Edema formation was associated with lowered serum protein. Increased blood chlorides occurred simultaneously with decreased gastric chlorides as well as lowered free and total gastric acidity. Studies of the serum p_H revealed no relationship between edema formation and acidosis. It was felt that the primary factor for edema formation is the lowering of the colloidal osmotic pressure of the plasma due to a low proteinemia.

A similar proteinemia in dogs was produced by Weech, Goettsch and Reeves³ by dietary means. The standard diet used by them results in a progressive decline in the concentration of protein in the serum. A composite curve constructed from the observations on twenty-one animals disclosed a rapid initial fall and a slower subsequent decrease in albumin and total protein and an approximately constant level for globulin, though the latter was subject to wide fluctuations in individual animals.

What, then, are the common denominators of the studies? Loss of protein from the blood, no matter in what way produced, introduces a factor of considerable metabolic importance. This is accompanied by a low protein osmotic pressure, which is probably the principal factor in the development of edema. The rela-

tionship of the albumin-globulin fractions is not quite so clear cut and may perhaps be of less significance. The other coexisting chemical changes have also not been shown to be constant enough to play a significant part in this type of edema. The next step should be the investigation of the factors initiating protein loss other than gross dietary deficiencies like that in so-called war edema.

Current Comment

VITAMIN D CONTENT OF CERTAIN MAMMALIAN LIVERS

Little information has heretofore been available on the vitamin D content of mammalian livers. Devaney and Munsell¹ have recently tested this factor in calf, beef, lamb and hog livers. The line test in rats from 4 to 5 weeks old was used in making the assays. At the end of the three weeks dietary depletion period several individuals of each litter were fed liver. At least one animal was given 0.2 unit of the international standard vitamin D, and one was usually continued on the basal diet alone. Allowance was made for the phosphorus in the liver feedings by adding extra calcium in the form of calcium carbonate to the Steenbock diet in amounts large enough to maintain the calcium-phosphorus ratio of the whole diet equal to that of the rachitic diet alone. The vitamin D potency of each type of liver was estimated by using a curve of reference relating degrees of healing to the number of vitamin D units. The comparison thus available showed that beef and hog liver had between 0.4 and 0.5 international unit of vitamin D per gram, while lamb liver had slightly less than 0.2 unit and calf liver only about 0.1 unit. Mammalian liver is thus shown as a possible significant source of vitamin D in addition to its other qualities. The content is, however, negligible in comparison with more familiar sources of vitamin D such as cod liver oil, which contains 85 units per gram, or 315 units per standard teaspoonful.

MORTALITY IN PEPTIC ULCER

The deaths charged to "ulcer of the stomach" in New York City from 1900 to 1933 forms the subject of a recent comment.¹ The death rate per hundred thousand of population has gone from 3.69 in 1900 to 6.77 in 1933, having reached its peak, 7.51, in 1928. On further examination the surprising fact is disclosed that there has been a definite decline in the death rate among females during this period. A striking change in the ratio between male and female deaths has thus occurred. At the beginning of the century the ratio was nearly 1:1, now it is approximately 5:1. A further apparent change in the mortality from peptic ulcer has been in the age group at which death occurred. Thus now, in sharp contrast with conditions three decades ago, the death rate in males has become high

at 40, even though the peak remains later in life. The reasons for the marked increase in mortality among males and the relatively earlier ages of death are uncertain. The answer is probably not to be found in consideration of mortality rates alone but must be sought in more inclusive morbidity studies.

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Chicago daylight saving time (3:30 central standard time). The next two broadcasts will be as follows:

June 20 Burns W. W. Bauer, M.D.
June 27 Blood and Fire W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15 Chicago daylight saving time (3 o'clock central standard time). The next two broadcasts will be as follows:

June 18 Only One Pair of Eyes W. W. Bauer, M.D.
June 25 Speaker and topic to be announced.

Note: After these talks, broadcasts on both networks will be discontinued until further notice.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bill Introduced—H 523 proposes to limit the retail distribution of articles, devices, drugs and medicinal preparations which may be used as contraceptives or for the prevention of venereal disease to licensed physicians and registered pharmacists.

CALIFORNIA

Bill Enacted—A. 603 has been enacted as c. 269, Laws, 1935, amending the law relating to county hospitals so as to require the admittance of any expectant mother, unable to pay for the necessary care, to any county hospital.

State Medical Election—Dr. Edward M. Pallette, Los Angeles, was chosen president-elect of the California Medical Association at the annual meeting, May 13-16, and Dr. Robert A. Peers, Colfax, was installed as president. Coronado was designated as the place for the next annual meeting.

Society News—Dr. Hugh Hampton Young, Baltimore, will address the San Francisco County Medical Society, June 28 on "Present Day Surgery of the Prostate."—Dr. Otto A. Houzicka, San Diego, addressed the San Diego County Medical Society, May 14, on "Infection in the Blood Stream."

Court Sustains Revocation of License—The district court of appeal of the second appellate district sustained the California Board of Medical Examiners, March 19, in revoking the license of Dr. Eugene J. Rinaldo. The board revoked the license, Oct. 18, 1932 on the charge that Rinaldo had presented fraudulent credentials for state licensure. In 1933 Superior Judge Wilson overruled the board's decision.

Bill Passed—A. 2441 has passed the Assembly, proposing to prohibit the sale of dinitrophenol or thyroid and compounds preparations or derivatives thereof, including all such substances as are or may hereafter be trade marked, patented or copyrighted and proprietary medicines, except on the written prescription of a licensed physician or "osteopathic physician duly licensed under the state medical practice act."

COLORADO

Society News—Speakers before the Medical Society of the City and County of Denver, April 2, were Drs. George L. Monson and George F. Netherton, on "Acute Thyroid Crisis Following Thyroidectomy," Clarence B. Ingraham, Jr., "The Problem of Contraception," and Theodore E. Beyer, "Retropharyngeal Abscess." The society was addressed, April 22, by Dr. Herbert McLean Evans, Berkeley, Calif., on "Newer Conceptions of Pituitary Functions."

CONNECTICUT

Bill Passed—H 852 has passed the House and the Senate, proposing to repeal the laws regulating the sale, distribution and possession of narcotic drugs and to enact what apparently is the uniform narcotic drug act.

Bills Enacted—The following bills have been enacted: S 396 requiring both parties to proposed marriages, as a condition precedent to obtaining licenses to wed, to present statements from licensed physicians that both parties have submitted to a Wassermann or Kahn or other similar laboratory blood test and that the result of such test has proved negative, and H 1152, authorizing the revocation of the license of any practitioner of the healing art who fails to file a birth certificate as required by law.

DISTRICT OF COLUMBIA

Medical Bills in Congress—*Bill Introduced* H R 8387, introduced by Representative Fenerty of Pennsylvania, proposes to require the commission on licensure to practice the healing art in the District of Columbia to issue a license to practice the healing art in the District of Columbia to Dr. Ronald A. Cox, Washington.

IDAHO

Annual Registration Due July 1—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1 with the Department of Law Enforcement, and at that time to pay a fee of \$2. If a licensee has not paid the annual registration fee by October 1, his license can be canceled but will be restored within five years thereafter on payment of the delinquent fees and a \$10 penalty. If a license has been canceled for more than five years, it can be reinstated only on the payment of \$25 and on the licensee's passing an examination the nature of which shall be determined by the Department of Law Enforcement.

ILLINOIS

Bill Passed—S 238 has passed the Senate, proposing to so amend the medical practice act as to create a board of chiropractic examiners.

Bill Introduced—H 1085, to amend the medical practice act, proposes to raise the examination fee paid by an applicant for a license to \$20 and to raise the fee for a license without examination to \$50.

Society News—Dr. Ralph A. Kinsella, St. Louis, discussed "Occlusion of the Coronary Arteries" before the Adams County Medical Society in Quincy May 15.—Dr. Abraham A. Low, Chicago, assistant state alienist, conducted a psychiatric clinic at the Anna State Hospital, Anna, April 25, before a special meeting of the Union County Medical Society.—At a meeting of the Peoria City Medical Society, June 4, Dr. Philip C. Jeans, Iowa City, discussed recent nutritional trends.—Dr. Clarence O. Sappington, Chicago, addressed the Central States Society of Industrial Medicine and Surgery at Rockford, May 21, on "Occupational Disease Hazards."

Academy of Science Meeting—The twenty-eighth annual meeting of the Illinois State Academy of Science was held at Bloomington, May 3-4. The following speakers, among others, participated in a program before the section on medicine and public health:

Dr. Joseph Howard Beard, health officer of the University of Illinois
Urban Rickets—Its Cause Effect and Prevention
Dr. Clarence O. Sappington consulting industrial hygienist Chicago
Significance of Occupational Diseases
Fred W. Tanner, Ph.D., head department of bacteriology University of Illinois
Efforts to Control Quality of Foods in the United States
Robert H. Gault, Ph.D., department of psychology Northwestern University
Evanston Some Implications of Vibrotactile Research

New Society of Bacteriologists—The Society of Illinois Bacteriologists was organized, May 8, at a meeting in the University of Illinois College of Medicine, Chicago, with Fred W. Tanner, Ph.D., Urbana, professor of bacteriology, University of Illinois, as president, Dr. Frederick O. Tonney, director of research Chicago Department of Health, vice president, and H. S. Shaughnessy, Ph.D., director of laboratories,

Illinois State Department of Public Health, Springfield secretary A board of eleven governors is to be selected, each representing a particular group of bacteriologists, with one elected at large. Five members will represent universities and other educational institutions. The new society will be the Illinois branch of the Society of American Bacteriologists.

Chicago

Dr Taliaferro Awarded the Chalmers Medal—The Chalmers Medal of the Royal Society of Tropical Medicine and Hygiene has been awarded to William H Taliaferro, Ph D, associate dean, Division of Biological Sciences, University of Chicago, and chairman of the department of hygiene and bacteriology, "in recognition of his valuable contributions to knowledge of the subject of animal immunity." The Chalmers Medal is granted every two years to a man under 45 years of age who has "contributed signally" to research in tropical medicine. Dr Taliaferro was recently appointed dean of the Division of Biological Sciences, succeeding Frank R Lillie, Ph D.

INDIANA

District Meetings—The thirty-first annual meeting of the Fourth District Medical Society was addressed in Rising Sun, May 16, among others, by Drs William B Adams, Hanover, on "Glandular Therapy."—At a joint meeting of the Fifth District Medical Society and the Vigo County Medical Society in Terre Haute, May 3, Dr Elmer L Sevringhaus, Madison, spoke on 'Pituitary and Ovarian Relationship in the Human Being'.—Speakers before the Sixth District Medical Society in Rushville, May 9, included Dr Stanley B Gordin, Connersville, on 'Uterine Hemorrhage'.—The Ninth District Medical Society was addressed in Tipton, May 22 among others, by Drs Luke W Hunt, Chicago, on "Scarlet Fever Immunization and Treatment", Aaron E Kanter, Chicago, "Practical Application of Gynecology for the General Practitioner," and George W Crile, Cleveland, "Acute Surgical Abdomen".—At a meeting of the Tenth District Medical Society in East Chicago, May 9, speakers were Drs Lewis M Hursthal, Boston, on 'Mechanism of Heart Beat and Electrocardiography', Ernest E Irons, Chicago, 'Arthritis', David S Hillis, Chicago, 'Treatment of Abortion', Isaac A Abt, Chicago, 'Care of the New-Born', Samuel W Becker, Chicago, 'Treatment of Syphilis,' and Max Cutler, Chicago, 'Newer Work in Treatment of Cancer by Radiation'. Dr Cutler also addressed the Eleventh District Medical Society in Delphi, May 15 on tumors, and Dr Everett E Padgett, Indianapolis, gallbladder disease.—Dr Thurman R Rice, Indianapolis, among others, addressed the Twelfth District Medical Society in Lake James, May 23, on 'The Art of Living'.

IOWA

State Medical Election—Dr Prince E Sawyer, Sioux City, was chosen president-elect of the Iowa State Medical Society at its annual meeting in Davenport, May 10. Dr Thomas A Burcham, Des Moines was inducted into the presidency. The next annual session will be held at Des Moines, May 13-15, 1936.

Dr MacEwen Named Dean of State University—The appointment of Dr Ewen M MacEwen, professor and head of the department of anatomy, State University of Iowa College of Medicine, Iowa City, as dean, is reported. Since the resignation of Dr Henry S Houghton in 1932, the affairs of the college have been in charge of an interim committee composed of Drs John T McClintock, Howard L Beye and Everett D Plass. Dr Houghton left Iowa to become associate dean of the Division of Biological Sciences and director of the University Clinics of the University of Chicago, he has since resigned at Chicago to become advisory representative of the China Medical Board. Dr MacEwen was born in Greenwich P E I Canada, and is a graduate of the State University of Iowa College of Medicine, class of 1912. He has been head of the department of anatomy since 1931.

KENTUCKY

Society News—Drs William T McConnell, Louisville, and Robert P Ball Chattanooga, Tenn, addressed the Jefferson County Medical Society, May 6, on 'Obstetrical Work in Louisville Hospitals in 1933' and 'X-Ray Examination of the Obstetric Patient, respectively'.—At a meeting of the Fifth District Medical Society in Carrollton, May 9 speakers were Drs Fred W Rankin Lexington, on 'Lesions of the Colon and Rectum', Louis G Herrmann, Cincinnati, 'Obliterative Arterial Diseases of the Extremities—Treatment by Passive Vascular Exercises' and Henry Kennon Dunham, Cincinnati, 'Treatment of the Tuberculous Patient in the Home'.

Dr L Wallace Frank addressed the Louisville Surgical Society, May 10, on "Carcinoma of the Lip, Tongue and Oral Cavity".—Dr James R Stites, Louisville, addressed the Society of Physicians and Surgeons, Louisville, May 16, on transurethral resection.—Dr Louis G Herrmann, Cincinnati, addressed the Louisville Medico-Chirurgical Society, April 12, on "The Physiologic-Pathologic Basis for the Treatment of Peripheral Vascular Diseases".—Drs Perry Bromberg, Nashville, Tenn., and William S Ehrlich, Evansville, Ind., addressed the Christian County Medical Society, Hopkinsville, April 16, on "Significance of Hematuria" and "Future Treatment of Prostatic Hypertrophy," respectively.

MICHIGAN

Personal—Howard B Lewis, Ph D, director of the University of Michigan College of Pharmacy and professor of physiological chemistry in the medical school, has been elected a member of the National Board of Medical Examiners of the United States, succeeding the late Prof Otto K O Folin of Harvard University.—Mr William J Burns, Detroit, executive secretary of the Wayne County Medical Society, was married, May 1, to Miss Josephine Alice Murphy. They left on an airplane for New York, going thence to California via the Panama Canal.—Dr Buell H Vanleuven, councilor of the thirteenth district, was elected mayor of Petoskey recently.—Dr Robert B Harkness, formerly of Houghton, has been named director of the health department of Eaton County.

Eight Physicians Presented with Life Memberships—At a testimonial dinner in the Jackson Country Club, Jackson April 11, life memberships in the Jackson County Medical Society were presented by eight physicians and one layman Mr C B Hayes. The physicians are Drs Joseph C Kugler, Frederick W Rogers, Arthur J Roberts, Henry Gray Glover, William W Lathrop, Walter E Spicer, Jackson, Herbert H Frazier, Hanover, and James McColgan, Grass Lake. Drs Frazier and McColgan were unable to be present. The dinner was in recognition of their long years of service in the practice of medicine. The youngest physician was Dr Frazier, who is 66 years of age, and the oldest, Dr Spicer, 80 years. Tribute was paid to Mr Hayes for his part in forwarding the industrial fortunes of Jackson.

NEW YORK

Health Officers' Conference—The annual conference of health officers and public health nurses will be held at Saratoga Springs, June 26-28. The State Association of School Physicians and of the American Association for Hygiene and Baths will meet at the same time.

Machine for Making Artificial Radium—An appropriation at the University of Rochester will be made to cover the cost of building a machine to manufacture artificial radium, newspapers announce. The device, called a five million volt accelerator, will be the second of its kind in the country and will be assembled during the summer in the Bausch and Lomb Building under the direction of Lee A Dubridge, Ph D. The machine will manufacture artificial radium at less expense than the cost of true radium.

New York City

County Society Library—The library of the Medical Society of the County of Kings reported that in 1934 readers using its facilities increased to 14 164 from 13 079 in 1933. The number of books consulted was 62,079, and the number taken out for home use was 10 620. During the year 782 volumes were added to the library. It received regularly 1,500 current serial publications.

Survey of Syphilis—The New York City Department of Health is cooperating with the U S Public Health Service in making a survey during June on the incidence of syphilis. To assure as complete returns as possible, each physician, hospital and clinic will be provided with suitable instructions and record forms. According to New York *Medical Week* the study will be confidential, intended primarily for statistical purposes and not for the purpose of checking against previous reports submitted by physicians and clinics. Two questions will be asked. The number of early and late cases of syphilis diagnosed for the first time during the month of June and the number of early and late cases diagnosed before June 1 but treated or observed during the month of June.

Woman's Hospital Eighty Years Old—The Woman's Hospital founded by Dr J Marion Sims in 1855, marked its eightieth anniversary May 4, by a display of historic instruments and souvenirs. Among them were a medal of the Legion of Honor of France given to Dr Sims by Napoleon III in

recognition of his treatment of the Empress Eugenie and a speculum used during the operation. Portraits of many persons identified with the hospital and a copy of "Frank Leslie's Illustrated Weekly," showing the hospital's celebration of its first anniversary, were also shown. The Woman's Hospital is said to have been the first hospital in the world to be financially sponsored by women for treatment of diseases of women. It has occupied three buildings, the present one dating from 1906.

Courses for Doctor of Medical Science Degree—Graduate courses in the departments of forensic medicine, medicine, ophthalmology, pediatrics, radiology and surgery, some of which may lead to the degree of doctor of medical science, are announced by New York University College of Medicine. For admission, the college requires graduation from an approved medical college, completion of internship in an approved hospital, and approval by the department in which the work is to be taken. For the degree the following requirements are listed: (1) Not less than three years' full time work or the equivalent in the university or in laboratories or hospitals recognized by it, with at least one year at New York University; (2) intensive graduate training in the basic sciences and other fields as recommended by the departments concerned; (3) active experience of not less than eighteen months of full time work or the equivalent in wards, clinics and diagnostic laboratories of the clinical specialty in which the work for the degree is being done; (4) satisfactory performance in examinations; and (5) a thesis based on original work. The university announces that courses not leading to the degree are also offered in the departments mentioned.

Council to Foster Research—Formation of the Research Council of the Department of Hospitals to foster medical research in the municipal hospitals is announced in New York *Medical Week*. Efforts will be made to improve treatment of chronic diseases through a clinical division under a director to be appointed by the commissioner of hospitals after nomination by the College of Physicians and Surgeons of Columbia University. Mr. Marshall Field is chairman of the council, Mr. George MacDonald, vice chairman and Dr. Bernard Sachs, treasurer. Among twenty-nine other members are the following physicians:

George Bachr	William H. Park	Samuel J. Kopeitzky
Ernst P. Boas	Douglas Symmers	James Alexander Miller
Arthur C. deGraft	Luther F. Warren	Walter W. Palmer
John A. Hartwell	Linn J. Boyd	Henry James Spencer
Emanuel Libman	Alfred E. Cohn	Bettina Warburg
Eugene L. Opie	Alphonse R. Dochez	

A public appeal is being made for \$25,000 to initiate the studies but it is hoped the city government will later appropriate funds to continue them.

OHIO

Health at Columbus—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended June 1, indicate that the highest mortality rate (20.3) appears for Columbus and the rate for the group of cities as a whole, 11.5. The mortality rate for Columbus for the corresponding period last year was 16.3 and for the group of cities, 11.2. The annual rate for eighty-six cities for the twenty-two weeks of 1935 was 12.4 as against a rate of 12.3 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may increase the death rate.

Graduate Clinic for Academy of Medicine—The department of postgraduate medicine of the University of Michigan School of Medicine offered its third annual clinic for the Toledo Academy of Medicine, May 22, at the University Hospital Ann Arbor. In the morning, Drs. Willis S. Peck, Cyrus W. Strickler Jr., and Carl F. Huber discussed 'Results of Therapeutic Fever'. Henry Field Jr., 'Fusospirochetal Pneumonia' and Paul S. Barker, 'Pituitary Basophilism'. The following physicians participated in the afternoon session:

Franklin D. Johnston	Value of the Phase Angle in Diagnosing Hypertension
Read M. Nesbit	Artificial Acidosis by Diet and Drugs in Treating Urinary Tract Infections
Stanley M. Goldhamer	Presence of the Blood Stimulating Factor in the Gastric Secretion of Patients with Pernicious Anemia
Richard H. Freyberg	Subcutaneous Insulin Injections and Their Reaction to the Stimulation of Appetite
Jerome W. Conn	Treatment of Diabetic Coma with Especial Relation to the Use of Sodium Bicarbonate
Frederick A. Collier	Water Balance in Preoperative and Postoperative Cases

OKLAHOMA

Society News—Dr. Horace Reed, Oklahoma City, addressed the Kingfisher County Medical Society, Kingfisher, recently, on health insurance and socialized medicine. The society adopted a resolution expressing its opposition to the health insurance movement.

State Medical Election—Dr. Charles H. Haralson, Tulsa, was chosen president-elect of the Oklahoma State Medical Association at its annual meeting, May 13-15, and Dr. Louis H. Ritzhaupt, Guthrie, was inducted into the presidency. The next annual session will be held at Enid.

PENNSYLVANIA

Bill Introduced—S. 1528 to amend the laws regulating the practice of osteopathy proposes to prohibit an osteopath from using the title 'Doctor' or the abbreviation 'Dr.' before his name without the word 'Osteopath' or 'Osteopathist' or the words 'Osteopathic Physician' immediately following his name.

Radiological Society Meeting—The Pennsylvania Radiological Society held its annual meeting in Pittsburgh, May 17-18. A symposium on radiation therapy was presented in the morning by Drs. Zoe Allison Johnston, Pittsburgh, John M. Keichline, Huntington, John F. McCullough, Pittsburgh, and Byron H. Jackson, Scranton, and Dr. Max Kahn, Baltimore. Other speakers included Drs. Josiah R. Eisaman, Pittsburgh, 'Roentgenological Study of the Chest with Iodized Oils'; George W. Grier, Pittsburgh, 'Colitis'; and Paul G. Bovard, Tarentum, 'Pneumoconiosis'.

Philadelphia

Abortionist Sentenced—T. R. Anderson, a Negro, was sentenced, April 11, to serve from one to five years in the state penitentiary for performing a criminal abortion and practicing medicine without a license.

Medical College News—Dr. Esther M. Greisheimer, associate professor of physiology at the University of Minnesota Medical School, gave a series of lectures at the Woman's Medical College of Pennsylvania during April on physiology of the nervous system. Dr. Evelyn M. Anderson of McGill University Faculty of Medicine, Montreal, is guest lecturer during May on physiology of the endocrine system. Dr. David Riesman, Philadelphia, delivered the first Alpha Omega Alpha lecture at the college, April 16, on 'Bases of Medical Ethics'. Dr. Edward Martin, emeritus professor of surgical physiology, University of Pennsylvania School of Medicine, was awarded the honorary degree of doctor of laws by Temple University, June 13. The University of Pennsylvania recently received a portrait of Dr. Philip Syng Physick by Thomas Sully. Dr. Physick was professor of surgery at the university from 1805 to 1819 and professor of anatomy from 1819 to 1831. The portrait was presented by Mrs. John F. Lewis.

Pittsburgh

Society News—Speakers at a meeting of the Pittsburgh Academy of Medicine, May 14, were Drs. Leslie H. Osmond on 'Present Status of Radiation Therapy'; James D. Heard, 'A Study of Electrocardiograms Derived from Eleven Fetuses Through the Medium of Direct Leads'; and Cortlandt W. W. Elkin, 'Evolution of Carbohydrate Diets in Diabetes Mellitus'. Dr. George E. Martin has been appointed director of the Pittsburgh Tuberculosis Hospital.

SOUTH DAKOTA

State Medical Election—Dr. James L. Stewart, Nemo, was chosen president-elect of the South Dakota State Medical Association at its annual meeting at Pierre, May 15, and Dr. Albert S. Rider, Flandreau, was installed as president. Dr. Earle A. Pittenger, Aberdeen, was named vice president and Dr. John F. D. Cook, Langford, reelected secretary. The next annual meeting will be held at Sioux Falls. It was tentatively announced that the session would be a joint one with the state dental association.

TEXAS

Hospital News—Three new units at the Veterans' Administration Facility, Waco, will be started about July 1. The administration has made \$1,081,500 available, including \$900,000 for 466 additional beds for white patients, 164 for Negroes and 138 for acute cases, it was stated.

State Medical Election—Dr. Howard R. Dudgeon, Waco, was chosen president-elect of the Texas State Medical Association at its annual meeting in Dallas, May 16, and Dr. John

H. Burleson, San Antonio, was inducted into the presidency. Vice presidents are Drs. Olin F. Gober, Temple Oscar M. Marchman, Dallas, and Thomas M. Dorbandt, San Antonio. The next annual session will be held in Houston.

District Meeting—The semiannual meeting of the South Texas District Medical Society was held in Beaumont, April 11-12. Among speakers were Drs. Titus H. Harris Galveston, on "Psychiatry as Related to General Medicine", Llewellyn H. Ledbetter, Beaumont, "Radiography of the Heart and Great Blood Vessels", John R. Phillips, Houston, "The Thyroid and Its Surgical Considerations" and George Sladczyk, Port Arthur, "Problems of Industrial Surgery". Dr. Samuel E. Thompson, Kerrville, spoke on medical economics at a banquet in the evening of April 11.

Society News—Drs. William S. Horn and Edwin G. Schwarz, Fort Worth, presented papers before the Tarrant County Medical Society, April 3, on "Pulmonary Indications for Therapeutic Abortion" and "Progress in Active and Passive Immunization of Children," respectively. Speakers before the Wichita County Medical Society, April 9, were Drs. Walter B. Whiting and Robert L. Hargrave, Wichita Falls, on diagnosis of heart disease and fibrosarcoma of the extremities, respectively. The Texas Society for Mental Hygiene was recently organized with Dr. James Shirley Sweeney, Dallas as president of the board of directors. Speakers at a special meeting of the Dallas County Medical Society, Dallas, May 2, were Drs. John O. McReynolds, on "Intra-Ocular Malignant Neoplasms", Robert L. Moore "Use of Sodium Lactate in Treatment of Acidosis", Glenn D. Carlson, "Multiple Myeloma," and Robert H. Milwee, "X-Rays and Radium in Carcinoma of the Cervix and Fungus."

VIRGINIA

Society News—Dr. Lewis E. Jarrett, superintendent of the hospital division, Medical College of Virginia, Richmond, was elected president of the Virginia Hospital Association at its annual meeting in conjunction with the associations of North and South Carolina in Greensboro, N. C., April 12. Drs. Arthur C. Christie and William P. Herbst Jr., Washington, D. C., addressed the Roanoke Academy of Medicine, April 1. Dr. Richard Kovacs, New York, addressed the Richmond Academy of Medicine, April 23, on the present status of physical therapy.

WASHINGTON

Society News—Speakers at the meeting of the King County Medical Society, Seattle, May 20 were Drs. Byrl R. Kirklin and David M. Berkman, Rochester, Minn., on roentgenologic examination of the alimentary tract and treatment of peptic ulcer, respectively.

Personal—Dr. Clyde B. Hutt has been named in charge of the city-county health department at Vancouver, succeeding Dr. Robert W. Armstrong, resigned. Dr. Walter Kelton, Seattle, has been appointed surgeon to federal prisoners to succeed Dr. Don H. Palmer, who resigned after several years' service. Dr. Walter C. Aylen has succeeded Dr. William H. Brandt as health officer of Auburn. Dr. Brandt has resigned.

Annual Graduate Course—The University of Washington, Seattle, will present its annual graduate course of lectures and clinics, July 15-19. Lecturers will be Drs. Arthur E. Hertzler, Halstead, Kan., who will deal with the thyroid, gastro-intestinal and gynecologic diseases, Oliver H. P. Pepper, Philadelphia, evolution of disease, heredity in diseases of the blood, late effects of congenital lesions trichiniasis, hypotension and Hodgkin's disease. Paul J. Hanzlik, Stanford University, digitalis, hypnotics, new metabolic stimulants and other pharmacologic subjects, and Russell S. Ferguson, New York, on applied urology with special emphasis on malignancy.

WISCONSIN

William Snow Miller Lecture—Leslie B. Arey, Ph.D., Robert Laughlin Rea, professor of anatomy, Northwestern University Medical School, Chicago, delivered the annual William Snow Miller lecture at the University of Wisconsin May 2. His subject was entitled "Factors That Influence the Course of Wound Healing."

Bill Passed—A. 422 has passed the Assembly and the Senate proposing to amend the laws relating to the practice of chiropractic so as to raise the annual registration fee required of chiropractors to \$5 and to make the annual registration of a chiropractor contingent on his attending within the preceding year at least one of the two day "educational" programs conducted by the Wisconsin Chiropractic Association.

Personal—Dr. Marcos Fernan-Nunez, professor of pathology and bacteriology, Marquette University School of Medicine, Milwaukee, has been elected an academician of the National Academy of Medicine of Spain. Dr. Herman A. Schulz, Edgar, has been appointed coroner of Marathon County, succeeding the late Dr. John R. M. Frawley, Wausau. Dr. William C. Felton has been elected health commissioner of Appleton, succeeding Dr. Frank P. Dohearty, who held the position for seven years.

PHILIPPINE ISLANDS

Society News—Dr. Pedro T. Lantin, Manila, addressed a recent meeting of the Bulacan Medical Society on "Blood Transfusion in the Treatment of Typhoid Fever." Speakers at the annual meeting of the Culion Medical Society in January were Drs. Jose O. Nolasco, Culion, on "The Leprosy Problem in the Philippines and Leprosy in Norway" and Drs. Casimiro B. Lara and Bonifacio de Vera, Culion, "Clinical Observations with Respect to Early Leprosy in Children of Lepers."

GENERAL

Bequests and Donations—The following bequests and donations have recently been announced:

Community Hospital Big Rapids, Mich. \$6,000 by the will of the late Mrs. C. H. Milner.

Under the wills of Louis and Henry L. Weinberger the following will receive \$10,000 each: Eaglesville Sanatorium, Jewish Hospital Association of Philadelphia, Temple University, Lankenau, Jefferson Medical College and University of Pennsylvania and Mount Sinai hospitals. \$2,000 each will go to Women's Homeopathic, Northern Liberties, Northwestern General, St. Luke's and Children's hospitals.

Memorial to Dr. O'Dwyer—The eleventh annual meeting of the American Association of the History of Medicine in Atlantic City, May 6, was dedicated to the memory of Joseph O'Dwyer, New York, who, fifty years ago, demonstrated improved laryngeal intubation and published his first article on the new life saving treatment of laryngeal diphtheria. Through the courtesy of Dr. James W. Crane of the University of Western Ontario Medical School, London, and Dr. Jabez H. Elliott, Toronto, there was exhibited at the meeting both Dr. O'Dwyer's "doctors' bag" in which he transported the intubation set and a model of all his instruments. Dr. Chevalier Jackson, Philadelphia, gave the address, reviewing Dr. O'Dwyer's life and his work. Dr. William S. Middleton, Madison, Wis., was elected president. Dr. Walter C. Alvarez, Rochester, Minn., vice president, and Dr. Edward J. G. Beardsley, Philadelphia, secretary. The next meeting will be held in Atlantic City in May 1936.

Society News—The new officers of the American Physiological Society are Drs. Frank C. Mann, Rochester, Minn., president; Andrew C. Ivy, Chicago, secretary, and Alexander Forbes, Boston, treasurer. Howard B. Lewis, Ph.D., Ann Arbor, was recently elected president of the American Society of Biological Chemists. Glenn E. Cullen, Ph.D., Cincinnati, vice president, Henry A. Mattill, Ph.D., Iowa City, secretary, and Dr. Cyrus H. Fiske, Boston, treasurer. Officers of the American Society for Pharmacology and Experimental Therapeutics elected at the recent annual meeting are Drs. Velyien E. Henderson, Toronto, president, Oscar H. Plant, Iowa City, vice president, Eugene M. K. Gelling, Baltimore, secretary, and Charles M. M. Gruber, Philadelphia, treasurer. Dr. Oskar Klotz, Toronto, was chosen president of the American Society for Experimental Pathology, recently Dr. Alphonse B. Dochez, New York, and Dr. Shields Warren, Boston, secretary. At the recent annual meeting of the Federation of American Societies for Experimental Biology, Dr. Velyien E. Henderson, Toronto, was named chairman of the executive committee. Dr. Eugene M. K. Gelling, Baltimore, secretary, and Dr. Charles M. M. Gruber, Philadelphia, treasurer. New officers of the Association of American Physicians, elected May 8, are Drs. Rollin T. Woodyatt, Chicago, president, Thomas R. Boggs, Baltimore, vice president, Hugh J. Morgan, Nashville, Tenn., secretary. The next annual session will be held at Atlantic City, May 5-6, 1936.

LATIN AMERICA

American Congress of Urology—The First American Congress of Urology, which was to have been held in Rio de Janeiro, January 21-26, was postponed and is now announced for August, according to information received by the U. S. Department of State. Physicians from the United States are invited to attend.

FOREIGN

Society News—The International League Against Rheumatism will hold its fifth congress at Lund, Sweden in September, 1936. Dr S Ingvar, professor of internal medicine, University of Lund, has been elected chairman and Dr Kåhlmeter, Stockholm, secretary. Further information may be obtained from the secretary of the league, Dr J van Breemen Keizersgracht 489, Amsterdam, Holland.

Congress on Gastro-Enterology in Brussels—Physicians from the United States who are to attend the First International Congress of Gastro Enterology to be held in Brussels, Belgium August 8 to 10, will make up a party on the S S Champlin which is scheduled to sail July 27. Complete information may be obtained from Dr Anthony Bassler 764 Park Avenue New York. Registration for the international congress will close on June 30. Application may be made to Dr George L. Laporte Jr, 129 East Ninety-First Street, New York.

Congress of Comparative Pathology—The third International Congress of Comparative Pathology will be held in Athens, Greece, April 15-18, 1936. Subjects on which special reports will be made are nephrosis and amyloidosis leishmaniasis, and spirochetosis and avitaminosis. The congress will study diseases of man and animals, including the relations existing between diseases of the different species, it will also study plant pathology and the relationship between certain plant and animal diseases. Further information may be obtained from Prof Anthony Codrums, 40, Didotou Street, Athens.

Memorial to Leon Bernard—The Health Organization of the League of Nations has announced the creation of a Leon Bernard Foundation for a prize in social medicine in memory of the late Professor Bernard, permanent representative of France to the health commission of the league. Dr Bernard was especially active in the international fight against tuberculosis and was secretary general of the International Union Against Tuberculosis. Contributions to the foundation are requested. They may be addressed to Dr Ludwik Rajchman medical director, Health Section, League of Nations, Geneva Switzerland.

New Medical Practice Act in Denmark—The first national law governing medical practice recently went into effect in Denmark, according to a report received by the U S Department of State. Beginning January 1, physicians were to be licensed only after having spent a year in a hospital and lying in station, under special circumstances, persons who have obtained the corresponding training in a foreign country may be authorized to practice. Foreigners may not practice unless they have become citizens, have lived in the country at least ten years and have obtained either regular authorization or special permission. Among other provisions of the new regulations are a ruling that physicians may not act or assume the title of specialist unless their qualifications have been recognized by a specialist council. Physicians are not allowed to operate a drug store or to be connected with the manufacture of drugs. They are obliged to extend first aid when called on. The law requires a physician to report to the department of health diseases or mental defects of patients who may constitute a danger to others, he is bound to secrecy, however, concerning professional information unless the law requires him to talk or if he feels it is in the interest of the public welfare to do so. Physicians are forbidden to strike. The law also provides that a physician may charge "a reasonable fee" for his services, furthermore, if a physician associated with a public hospital is entitled to payment the amount is fixed by the regulations of the hospital. Rigid regulations against quackery are included in the new law. According to the report, "a quack doctor who exposes the health of a patient to danger through the treatment of infectious diseases or by operations or through cures at private clinics shall be punished by imprisonment of up to three months." A person who gives the impression through advertising or otherwise that he is a physician is to be fined and a physician who cooperates with a quack is also liable to fines or imprisonment.

CORRECTION

Relapsing Fever in the United States—In the article by Dr James O Gillespie in THE JOURNAL, May 25 page 1878 appears the statement "A single intravenous injection of neoarsphenamine, 0.1 Gm for each kilogram of body weight, administered at the onset of a paroxysm, will effect a cure in practically every case." Obviously this should of course, read 0.01 Gm for each kilogram.

Report of Conference on the Reform of Medical Education

The reform of medical education has been under discussion for years. Last year the British Medical Association made a report on the subject (THE JOURNAL, May 26, 1934, p 1772). There has been published now the report of a conference of representatives nominated by the Universities of Oxford, Cambridge and London, the Royal College of Physicians, the Royal College of Surgeons and the Society of Apothecaries on the medical curriculum all leading teachers of the day. Their recommendations, which follow, will if carried into effect mark an epoch in medical education in this country.

The object is to give the student "such knowledge and such education as will enable him to approach the problems of practice with some degree of confidence and with legitimate hope that his scientific outlook on health and disease will enable him to learn from subsequent observation and experience." The rumous policy of surcharging the memory with facts is condemned. The course of instruction is divided into three main parts—premedical, preclinical and clinical. In the premedical period the future medical student should not receive special instruction, as is done at present, but should study science with his fellow pupils. It is also recommended that the first M B or examination in the basic sciences might be taken before matriculation by means of a higher school certificate. This would ensure the continuance of the general education after matriculation. The minimum length of the medical curriculum should not be extended beyond the present five years. Medical studies proper, i.e. anatomy and physiology, should not be begun before the age of 18.

THE PRECLINICAL PERIOD

During the first two years of medical studies the work of the student should be arranged by a board of teachers representing anatomy, physiology, chemistry, biochemistry, pharmacology and pathology. During the first four terms of medical studies the student should continue the study of chemistry, work in the dissecting room and department of anatomy, and in the second term begin the study of elementary physiology and biochemistry. During the fifth and sixth terms, while continuing anatomy and physiology, he should be introduced to the principles of general pathology, immunology and bacteriology by a pathologist. The teaching of organic, physical and colloidal chemistry should be determined by a conference between the teachers of physiology, biochemistry and chemistry, due weight being given to the opinions of the teachers of physiology on the special needs of medical students. The teacher of anatomy should be given access to hospital material for the teaching of applied anatomy, with or without the assistance of a clinician. During the second year of medical studies the teacher of physiology, being provided, if necessary for this purpose, with a clinical assistant, should give demonstrations in applied physiology and familiarize the student with use of the stethoscope, ophthalmoscope, laryngoscope and otoscope. During this year the teaching of pharmacology, including toxicology, should be arranged in close cooperation with the teachers of physiology. The student should also attend a short course of elementary medical psychology.

At the end of two years' medical study there should be an examination by a board of representatives of anatomy, physiology, pharmacology and pathology. There should be no separate examination in organic chemistry, but knowledge of this

subject should be tested in the examination in physiology. There should be no separate examination in pharmacology. A reduction should be made in the amount of detail required in the examination in anatomy.

THE CLINICAL PERIOD

Throughout the clinical period, pathology should be taught by the pathologist continuously in close association with the bedside study of disease, so that the student will instinctively think in terms of pathology. There should be a short course in public health, including forensic medicine, and the main part of the course should be under the direction of a member of the public health service selected for his ability to teach. Fortnightly demonstration should be given in the wards of a hospital of patients illustrating the common "mental" or "nervous" disorders associated with illness of any kind. In addition, the student should attend at least six demonstrations at a mental hospital and receive instruction in regard to insanity and mental deficiency.

Accidental Perforation of the Internal Jugular Vein During Operation

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, Mr. R. Atkinson Stoney reported an unusual accident that occurred during phrenic avulsion under local anesthesia. When the deep fascia covering the scalenus anticus was exposed, the assistant, who was using a blunt hook to retract the omohyoid, changed it to retract the outer border of the sternomastoid and in so doing perforated the internal jugular vein. The hemorrhage was checked by pressure of the vein forward against the sternomastoid. It was found impossible to catch the torn portion of the vein in forceps, but by including a portion of the sternomastoid muscle the vein could be occluded above and below the injury in large clamps. Then the vein was isolated and a double catgut ligature was passed with an aneurysm needle and tied above and below the tear. The nerve was then found and evulsed in the ordinary way. As the patient was not under a general anesthetic and the incision was limited, the difficulty of isolating and tying the vein was considerable. In view of such a possibility, Mr. Stoney thought that it would be advisable to avoid the use of a blunt hook in this operation, since, though the operator had a good view of the internal jugular, his assistant on the other side of the table had not and was liable to overlook the fact that it lay immediately under cover of the posterior border of the sternomastoid and was exposed to injury. The patient suffered no ill effects and the wound healed normally.

The Eight Hundredth Anniversary of Maimonides

The Bodleian Library, Oxford, has put on exhibition some famous manuscripts in the handwriting of the philosopher-physician Moses Maimonides, with many translations and first editions to celebrate the eight hundredth anniversary of his birth. Moses ben Maimon, usually called Maimonides, was the most important Jewish scholar of the middle ages. He left Spain in 1160, spent five years at Fez and passed on to Egypt, where he remained until his death at Cairo in 1204. He became celebrated as an authority on Jewish dogma and law, which he was the first to codify in his work *Misneh-Torah*, produced in 1180. But by profession he was a physician and acted in that capacity for Saladin and his sons. He wrote a number of medical books, which appeared in Arabic, though he appears to have used the Hebrew alphabet himself. He is best known by his great philosophical work "Guide for the Perplexed," which was soon translated into Latin and had a considerable influence on medieval philosophy.

The sister University of Cambridge is celebrating the anniversary by an exhibition of manuscripts and early printed editions and also by the following series of lectures: "The Philosophical System of Maimonides and Its Place in the History

of Thought," by Dr. S. Atlas, formerly professor of philosophy at Warsaw, "Maimonides' Theory of the State," by Dr. E. Rosenthal, and "The Place of Maimonides in Medicine and Science," by Dr. A. P. Cawadiaz. The British Museum has also put out an exhibition of the works of Maimonides.

May 10, 1935

Identity of Inguinal Lymphogranulomatosis and Certain Forms of Rectocolitis

At the April 9 meeting of the Academy of Medicine, C. Levaditi, Mollaret and Reimé reported the results of an experimental study as an answer to some doubts as to the identity of the etiology of inguinal lymphogranulomatosis and certain proliferative forms of rectocolitis, expressed by Frei at the 1934 session of the French Surgical Congress. Levaditi and his associates demonstrate, in the present paper, the absolute identity between the lymphogranulomatous virus isolated from a case of primary rectocolitis and that isolated from the inguinal lymph nodes in cases of true Nicolas-Favre disease. This identity is corroborated by experiments on animals, such as the chimpanzee and the mouse, which are susceptible to inoculation with the virus, as well as by inoculations of patients suffering from dementia paralytica. The inoculation of the virus obtained in the case of rectocolitis into the inguinal lymph nodes in a case of dementia paralytica resulted in a swelling of the lymph nodes and a perilymphadenitis, with an accompanying specific allergic state toward the antigen prepared by Frei as well as toward an antigen prepared with the virus from a patient with the Nicolas-Favre disease, which had been inoculated successively into monkeys. All these experimental proofs show that the pathogenesis of the Nicolas-Favre disease and certain proliferative forms of rectocolitis is the same. They are both due to the ultravirus of lymphogranulomatosis.

A New Protest by Medical Students

A renewed protest of French medical students against the foreign invasion of the profession took place March 29. Instead of riotous demonstrations such as occurred in February, one witnessed a dignified assembly in which the speeches were more temperate in character. Only one incident occurred to mar the occasion. One of the strikers invaded the pharmacology laboratory in the Paris Medical School and was repulsed with a bottle of formaldehyde solution. The report immediately spread to the crowds in front of the building that the person who defended the invasion of the laboratory had been one of the female instructors. When she left the building, unconscious of having been supposed to be the person who liberated the formaldehyde fumes, she was attacked, her clothes were torn off, and she would have been badly beaten had not the police intervened. On the following day, 2,000 students met in the courtyard of the school and in a more calm and dignified manner gathered round their leader, who expressed their grievances. Of 6,000 physicians in the department in which Paris is situated, more than 1,000 were said to be foreigners. Many foreigners had taken advantage of the laxity of the French laws and had not been obliged to comply with the same preliminary requirements, such as the passing of the bachelor of arts examinations, which French students must fulfil before being admitted to the medical schools. Furthermore, many foreign students, when they were admitted, contemplated only passing the final examinations leading to a degree, which did not permit them to practice medicine in France and its colonies. However, through laxity on the part of some of the faculties, this 'honorary' had been allowed to be converted into a "state" diploma.

Foreigners have always been welcomed to France and every possible facility has been placed at their disposal to profit by their stay here.

After parading the streets around the medical school, in the single file so typical of French students, under police escort the assembly returned to the classrooms, hoping that their protests, supported by the warm endorsements of medical societies and the new laws, would have the necessary effect in checking the crowding out of the native by foreign students.

Opinion on the Foreign Physicians Question

In the April 21 issue of the *Concours médical* the question that has led to so much acrimonious discussion and to student strikes during the last four months was fully revived by Laville, one of the editors. He quoted previous articles on the same subject by other members of the staff, stating that a foreigner who wished to practice in France must complete the same course of studies and the same length of military service as French citizens.

Furthermore, if the law proposed should be passed a foreigner must have been naturalized a minimum of ten years before graduation. The invasion of the profession by foreigners had become a grave menace to those born in France. The students could not be blamed for making a protest, in view of their future prospects of earning a living in their own country.

Laville stated that France had always received with open arms and was proud to be considered a haven of refuge for Russian aristocrats, antifascist Italians, German Jews and monarchist Spaniards. The French felt themselves honored to have students of all nations take advantage of the educational opportunities. Unfortunately, some of these refugees took advantage of the hospitality extended to them to continue their propaganda and to start riots and other objectionable incidents. Many of these foreigners have not, as in other countries been fused, in the 'melting pot,' to become citizens that France could be proud of. The medical profession is gravely menaced; the younger generation feels it keenly, and hence France must take every possible measure to prevent further abuse of its hospitality. Regrettable as it would seem to many of the profession who feel flattered that French culture should attract so many foreigners, self protection demands stricter measures in the future to prevent French physicians from being crowded out by foreigners who do not intend or are unable to return to their native lands to practice.

Measures to Combat the Effects of Gas Attacks

Although the war clouds are dispersed for the present, the people living in Paris and its immediate vicinity will soon be awakened from their lethargy, in the form of demonstrations on May 28 as to the method of dealing with incendiary bombs. All the procedures now employed in Italy will be demonstrated with the aid of the Italian air attaché. Similar meetings have been held in other European countries. A sort of general rehearsal will be staged as to how the civilian population should behave during gas attacks.

Two issues of the *Paris médical*, those of March 30 and April 13, are devoted to 'gaz de combat'. In the first issue Moynier summarizes the present knowledge of the clinical lesions due to gas in war, the treatment of intoxications and the classification of gases employed as suffocants, vesicants, those with general toxic effects and irritant toxic gases, and he presents a plan of organization for the care of civilians and soldiers exposed to gas. In the April 13 issue the elements of military toxicology are discussed by Cordier and Magne, the bases of protection against combat gases by Renault, and the collective protection of civilian populations against gas attacks by Dubrisay.

These articles show that these questions have again assumed the importance they enjoyed during the World War.

BERLIN

(From Our Regular Correspondent)

April 8, 1935

University Students and University Study

The feeling of unrest that has manifested itself among the students of Germany for some time appears to be gradually subsiding. The authorities are taking a different attitude toward the students and are beginning to insist that the demands of politics and of sports shall not be allowed to interfere with scientific work. The student corporations, or fraternities, have succeeded in resisting the exertion of any undue political influence on their societies, which threatened the very existence of their organizations. Nevertheless, a division within the "corporations" has taken place the dividing line being the degree to which national-socialist principles have been carried out. Recently the 'Gemeinschaft Studentischer Verbände' was created which "approves the principles of the 'corporations' of German students" but supports also the tenets of the national-socialist party. It is hoped that the creation of this "gemeinschaft" will settle all difficulties within the "corporations."

Importance is attached to a number of new decrees promulgated by the minister having jurisdiction. Among other changes he has issued a new penal code applicable to students, whereby the penal power of the German universities is made uniform. As had already been done with reference to the administration of the universities, the rector, or president, has been given a preeminent position of power as the preserver of discipline. According to the new penal code for universities, misdemeanors on the part of students will be punished from the standpoint of honor, the imposition of fines and university-prison (karzer) sentences having been abolished. The impossible penalties are oral reproof, written rebuke, withholding of credit for the current semester, expulsion from the university and, finally, exclusion from study at any German university.

The limitations imposed last year on the admission of graduates from secondary schools to university study (THE JOURNAL, March 3, 1934, p. 710) have recently been abolished by the federal minister of education. Now, as before, all such graduates may be admitted to university study. They must, however, first perform their duties in the government labor camps. The reasons assigned for such action are of interest. It is stated that 'the attendance at all German universities has fallen off to such an extent that the restrictions on admission to university study, such as were imposed last year, no longer seem necessary.' Of late (before the issuance of any special order) the restrictions had been applied in a more liberal manner. It is now the plan to make a careful selection of suitable pupils within the schools, concerning which special instructions will be issued later.

In the smaller university towns, in which a large portion of the population is dependent on the students for a living, the decline in attendance resulting from the imposition of too drastic restrictions had awakened great concern, particularly because of the fact that the students who are compelled to supplement their income by doing various forms of work have been inclined to enter a university located in a large city, where opportunities for securing part-time work are more frequent than in the smaller towns. For example, Tübingen, a famous old university town with 23,000 inhabitants had about 3,500 students in the summer semester of 1933 but the number had dropped to 2,500 in the summer of 1934. To combat this tendency, the minister of education has issued an order limiting the number of students to be admitted to the universities located in the large cities. The faculties in the large cities may admit only 70 per cent of the registration recorded for the summer semester of 1934. For the University of Berlin (including the newly annexed schools of agriculture and veterinary science) the maximum is 5,600 students; for Munich it is 5,000; Leipzig 3,100; Münster (West-

phalia) 2 500, Cologne 2 300, Hamburg 1,600 and Frankfurt-on-Main 1,400. In case all applicants cannot be admitted, preference is given to those students in moderate circumstances who desire to study in their home town, in order to keep down expenses. Foreign students are not included in the maximum number that may be admitted.

The number of women students of medicine in the winter semester 1933-1934 showed a decrease of 22 per cent, as against the registration for the previous winter semester.

For the summer semester of 1932 the number of Jewish medical students was 1,893. For the summer semester of 1933, after the installation in power of the national-socialist party, the registration dropped to 916, and for the winter semester of 1933-1934 to 366, or a reduction of 80 per cent under the registration for the summer semester of 1932. According to private estimates there were no more than 200 Jewish medical students in the summer semester of 1934, and since then the number has doubtless been still further reduced. These figures concern only students who belong to the Jewish faith. No statistics on "non-Aryans" have been reported.

Nothing of importance has been announced in regard to the character of the scholarship of medical students under the new regime, but the report of the chairman of the federal board of examiners in jurisprudence, in which he gives his observations on the results of the 1934 examinations in law, is significant for the formation of an opinion on the character of the scholarship in general. About 88 per cent of the candidates passed, to be sure, the prescribed tests but there was an evident reduction in the percentage of students whose performances were above the average, or who displayed a high type of scholarship, and a consequent increase in the number of students who secured a barely passing grade. The majority of the candidates may doubtless be said to have lacked the preparation that might be expected of them. It may be presumed that they did not receive adequate instruction.

A survey of the practical operation of the students' work service may be of interest. Of about 13,000 graduates of the secondary schools, who, by reason of the compulsory students' work service (*THE JOURNAL*, January 12, p. 132), filed requests, this spring, for admission to the labor camps, about 1,000 had to be rejected for the present, because of physical unfitness or because the ranks in the labor camps were already filled. The German student body, in cooperation with the management of the work service, is planning to find employment for the rejected group by organizing work in the rural and the subsistence homestead services.

"The Wonders of Life"—An Exhibit

This year's foremost exhibit, organized by the city of Berlin, is called "The Wonders of Life." The exhibit is organized in accordance with four different aspects: (1) the theory of life, (2) the carriers of life, (3) preservation of life, and (4) life's abodes. The preparation of division 1 was entrusted to the Museum of Hygiene in Dresden. With the aid of ingenious models an attempt is made to explain the functions of the various organs. The relations of the organs to one another are clarified by the well known model of the transparent man, which was designed by the Hygiene-Museum. Other models serve other purposes, for example the combined area (100 square meters) of the surface of the lungs is given a graphic demonstration by means of a delicate wire network, while another model that contains 32 cubic meters of air serves as an aid in visualizing the amount of air inspired daily. Similar devices are used to illustrate the circulation of the blood and other functions of the body.

In division 2 the family is represented as the center and the carrier, so to speak, of all manifestations of human life, the individual man is put in the background. This hall was constructed by the national-socialist department of public welfare. A set of chimes announces with the rhythmic repetition of its

nine strokes that every five minutes nine children are born in the German reich. Many charts of the federal bureau of statistics are displayed, among others, a chart illustrating the mode of organization and the services rendered by the Winterhilfswerk, which organization provides for the needs of persons who are destitute in winter. Also the training of the woman for the duties of the home is represented in form and picture: the training of the young woman for the duties of motherhood and the care of a household and family, including infant care and care of the health of a household. Division 3 is devoted to the preservation of life. The negative side (for example, the combating of venereal diseases) has been studiously placed in the background, the chief emphasis being laid on the positive tasks, such as protection of motherhood, care of a family, or occupational health protection. Division 4, Life's Abodes, was prepared by the federal homestead bureau. A homesteader's simple dwelling in natural size is presented. A detailed demonstration of a so called subsistence homestead (*siedlung*), including the planting of the garden, is given. The purpose of the homesteading plan is to afford the city dweller, and particularly the laborer, an opportunity to own his own home, together with a garden plot. In this connection attention is called to the fact that in Berlin there are still 50,000 persons living in unhygienic basement and attic apartments, while approximately 125,000 persons are eking out a miserable existence in their untidy settlements on the outskirts of Berlin.

ITALY

(From Our Regular Correspondent)

March 31, 1935

The Prevention of Blindness

Professor Federici, the new director of the Clinica oculistica of Bari, gave recently his introductory lecture, in which he illustrated the modern methods for the prevention of blindness. Trachoma, conjunctivitis purulenta neonatorum, syphilis and tuberculosis are the chief causes of blindness. Trachoma is widely diffused in Italy, particularly in the southern provinces and in the islands in which the population is more dense. Trachoma must be regarded as an infectious and contagious disease, although the etiologic agent is not known. The central government and other public bodies have established free dispensaries, amounting in number to 312. In southern Italy alone, about 100,000 trachomatous persons each year receive treatment. The patients who present the gravest symptoms are hospitalized. In the schools the trachomatous children are isolated. The general progress of recent years, including more hygienic dwellings, better drainage, the founding of schools and colonies, and the construction of aqueducts, has rendered great aid. Conjunctivitis purulenta blennorrhagica neonatorum also is usually a reflection of poverty and ignorance. The number of persons who have become blind because of this disease is today much diminished, because of the wide diffusion of dispensaries to combat venereal diseases which are aided by the central government. In the same manner, effective results have been secured in combating syphilis.

The crusade against tuberculosis in Italy is nation wide and is accomplished through the creation of dispensaries. Aside from the fact that the mortality from tuberculosis has been notably reduced (the total annual number of deaths from tuberculosis has dropped from 65,000 to 35,000) there has been also an evident reduction of blindness due to tuberculosis of the eye.

The Medicosurgical Society of Padua

The Societa medico-chirurgica di Padova met recently under the chairmanship of Professor Truffi. Frontali spoke on the hemolytic factor in the splenic anemia of infants. In eleven cases he observed that the disease developed almost silently between the sixth and the twelfth month of life, with waxen pallor associated with skeletal changes of a rachitic type. The blood

picture showed reduction of the red corpuscles and the hemo-
globin, and increase of the white corpuscles. There was also
erythroblastosis, with some microcytosis. The hemoglobin
exchange revealed a hyperhemolysis and bilirubinemia, with
an indirect positive van den Bergh reaction. The corpuscular
resistance was normal. Frontal assigns importance to a hemo-
lytic factor in the genesis of splenic anemia even if the corpus-
cular resistance is not diminished.

Belloni and Zoldan spoke on optic atrophy in tabes, with
binasal hemianopia and presented a case that appeared to be
the thirteenth described in the literature. The increase in the
pressure of the cerebrospinal fluid caused the speakers to take
account of the theory of Walker and Cushing with respect to
the genesis of hemianopia as a result of hydrops of the third
ventricle, but they reached the conclusion that the theory was
not applicable to their case.

Frontal and Rasi dealt with familial hemorrhagic icterus
with erythroblastosis and with increased corpuscular resistance.
In two brothers, one aged $7\frac{1}{2}$ and the other 9 years, the speak-
ers observed pallor from the first year of life, and a slight
icterus in the older child, which became exacerbated under the
influence of intercurrent infectious diseases. Both children pre-
sented hepatomegaly and splenomegaly, oligocythemia, erythro-
blastosis, oligochromemia, increased corpuscular resistance and
increased hemoglobin exchange. The speakers tested the resis-
tance of the red corpuscles of the two patients as compared
with the plasma of healthy subjects belonging to the same
blood group.

This last test furnished evidence of a diminished resistance
of the healthy red corpuscles when they are measured in con-
tact with the plasma of the patients. Research to discover in
what part of the plasma the substance that favors the hemolysis
is found has shown that the ultrafiltrate that contains the
crystalloids of the plasma exerts also the hemolyzing influence
whereas this is not observed in the colloidal portion that
remains above the filtrate. The speakers concluded that splenic
anemia of infants may assume, by imperceptible degrees, the
characteristics of familial hemolytic icterus either with normal
or with increased corpuscular resistance.

Medical Aid for the War Injured

In a recent announcement the Opera nazionale per la pro-
tezione ed assistenza agli invalidi di guerra stated the condi-
tions governing medical aid to disabled persons, to their orphans
and to their children until they reach the age of 15, and in
exceptional cases until they are 18 years old.

Admission to a hospital will be granted to disabled persons
only in case the present condition has a direct relation to the
wounds and diseases for which they obtained a pension. The
admission, if it is not of an urgent character, must be authorized
by the Opera, which will not grant it in cases adjudged chronic
or incurable. The president of the Opera has created a central
bureau for consultation. The treatment of tuberculosis and
pretuberculous conditions in the children of the disabled will
be turned over to the provincial antituberculosis societies or
to the Opera nazionale per la protezione della maternità e
infanzia. For adenoidectomies and tonsillectomies, authoriza-
tion must be secured from the headquarters of the society.
Balneothermal treatment for disabled persons and their families
has been abolished. Disabled persons affected with sequels of
epidemic encephalitis may be admitted to a clinic or specialized
institute for a maximal period of three months.

Personals

Prof Luigi Torraca, ordinarius in surgical pathology, has
been called to succeed Pascale Giacomo senator, to the chair
of clinical surgery at the University of Naples.

Prof. Paolo Gaifami has been appointed director of the
obstetric-gynecologic clinic of the University of Rome, to fill
the vacancy caused by the death of Professor Pestalozza.

VIENNA

(From Our Regular Correspondent)

March 20, 1935

Survey of Laryngeal Cancer in the Hajek Clinic

Professor Dr Hajek delivered recently, before the Vienna
Laryngologic Society, an address on laryngeal cancer. During
the fifteen years (1919-1934) that he served as director of the
Vienna Laryngorhinologic Clinic, 393 cases came to operation.
He emphasized that, during the first part of his work, health
conditions among the population, owing to after-effects of the
war were bad. The patients who came to the clinic were
weakened and their teeth were frequently carious. When they
applied for treatment, the disease was in an advanced stage.
With regard to the indications for laryngofissure, one had to
go much further than had been the custom, because many
patients refused to submit to the more extensive, radical opera-
tion. Patients above the age of 70, in whom the disease had
not progressed so far as in the younger patients, were scarcely
ever subjected to the operation. In seventy-nine of the 393
cases, laryngofissure was applied, and in 256 cases (fifteen
women) lateral pharyngotomy was employed. This was a real
opportunity of obtaining a survey of the operability of laryn-
geal cancer. Of the seventy-nine patients operated on by
laryngofissure 15 per cent died postoperatively, within twenty
days. 32 per cent died within three years, and 40 per cent
remained well for from three to ten years. Of those who died
within three years, 40 per cent succumbed to a recurrence.
40 per cent had to submit to a second operation (this time total
extirpation), and 10 per cent died from intercurrent diseases.
In the group that remained well for from three to ten years
11 per cent lived from three to five years, 54 per cent ten years
and 34 per cent more than ten years after the operation. Of
the cases in which the operation was plainly indicated not one
showed a recurrence within three years. Of the cases with
mild, extended indications however, 36 per cent presented
recurrences. Total extirpation was carried out in 279 cases,
in eighty-nine of which the tumor had not yet gone beyond
the region of the larynx. The tabulation shows the distribu-
tion of cases in men according to age groups.

Age groups	30-40	40-50	50-60	60-70	70-80	
	Years	Years	Years	Years	Years	
No. of cases	7	52	102	74	6	Total 241 cases

Of the eighty-nine patients with cancer limited to the larynx,
19 per cent died postoperatively (within twenty days), 32 per
cent remained well for three years, 22 per cent of these devel-
oping recurrences and 34 per cent remained well more than
three years (with 4 per cent of recurrences), a few more than
ten years. Of the 152 patients with cancer in and beyond the
larynx, 25 per cent died postoperatively and 48 per cent remained
well for three years, with 38 per cent developing recurrences,
and 17 per cent remained well more than three years, with only
13 per cent of recurrences within three to ten years. It is
evident therefore, that total extirpation of cancer, if the patient
remains well for three years, gives good results. Even in the
especially malignant cases, in which, however, a complete opera-
tion with total elimination of glands could be performed, it
was found that glandular complications need not be regarded
as an absolute contraindication to the radical operation. Thirty
per cent of such patients died postoperatively, but 15 per cent
survived the five-year period. It is true that carcinomas of
the larynx have been treated with radium and with x-rays,
but this study is concerned solely with operative therapy. In
regard to the ray treatment, no final judgment can be rendered
as yet. Hajek reported his observations also in cases in which
ligation of the common carotid was required. Of the eight
patients subjected to this intervention, four died from the
effects and four survived. In addition to seventy-nine laryngo-
fissures and 279 total extirpations, there were forty-three cases

that necessitated an incomplete operation. The pathologic changes were so extensive that the radical operation was impossible. The operative results were of course poor. Such cases belong rather to the field of ray treatment. In summing up, Hajek emphasized that the radical operation in cancer of the larynx, when performed by an experienced surgeon, offers favorable changes for recovery. It should be added that, if suitable speech training is applied, it is possible, even in total resection of the larynx, to develop in the patient a usable speaking voice, as Prof. H. Stern in the same clinic has repeatedly demonstrated.

The Sesquicentennial of the Vienna General Hospital

In May the sesquicentennial anniversary of the famous Vienna General Hospital will be celebrated in a ceremonial manner. All the physicians of the world who received their training in the clinics of this hospital have been invited to participate in the festivities. A large influx of physicians from Europe and overseas is expected. Up to the World War, the Vienna General Hospital was one of the most important centers of medical education in the world—a veritable mecca of physicians. Its foundation goes back to the time of Emperor Joseph II, who was considered the founder of democracy in central Europe and the most liberal and advanced ruler of his day. In 1784 he laid the corner-stone of the building, which he dedicated "zum Wohle und zum Heile des Volkes," as the original inscription over the entrance gate still reads. The celebration should have been held last year, but because of political disturbances it had to be postponed. The hospital in its extent and in its arrangement has remained almost exactly as it was 150 years ago. An architectural feature is the so-called Narrenturm, a circular structure that was originally intended for mental patients—as far back as 1815, but which now is used only as a dormitory and for administration purposes. The circular arrangement of the "cells," as in modern prisons, facilitated the supervision of the mental patients, for at that time no attempts to treat mental patients were made. The "old" general hospital comprises 1,800 beds, but in case of need the capacity can be increased to 2,400. It is closely connected with the new general hospital, which houses chiefly the clinics which were constructed thirty years ago and elaborately, even extravagantly, equipped in the most modern manner. Likewise the old hospital, which in its external form presents the same original appearance, has been transformed in its interior, including the laboratories and scientific institutes, into a thoroughly modern, first-class institution.

Prof. Dr. Norbert Ortner

The internist Prof. Dr. Norbert Ortner died recently, at the age of 70, from bulbar paralysis, from which he had suffered for years. He began his career as pathologic anatomist at the institute of Professor Weichselbaum but later turned his attention to internal medicine and became the assistant of Professor Neusser. He afterward removed to Innsbruck as professor of internal medicine. His first research was concerned with the pathology of the blood and the circulatory apparatus. His most important works are "Treatment of Internal Diseases," which has been translated into many languages and his book on "Pain." Since 1911 he had been the director of the second medical clinic in the general hospital in Vienna and had played an important part in training a large number of the prominent clinicians in Austria and Germany. His private practice was enormous, his advice being much sought by foreigners. He was physician to the aged emperor Francis Joseph until the latter's death. Three years ago Ortner was compelled to give up his medical practice. Professor Dr. Jagic succeeded him in the direction of the clinic.

RIO DE JANEIRO

(From Our Regular Correspondent)

March 15, 1935

Ticks as Transmitters of Typhus

Dr. Toledo Puza recently lectured before the Sociedade de Biologia of São Paulo on the role of ticks in transmission of typhus. He observed outbreaks of exanthematous typhus in rural areas in São Paulo in persons without either head lice or body lice, in whom the disease was related to the bite of ticks. Patients frequently enter the hospital with ticks still adherent to the skin. A woman who for the first time in her life was in a rural district was bitten by a tick. She showed an exanthematous patch around the bite and later developed typhus. Another patient developed typhus one day after his infestation with ticks, showing that the period of incubation in man may be short. The parasites were still adherent to the skin of this patient. These cases are equivalent to experiments on human beings. Dr. F. Lemos Monteiro succeeded in transmitting typhus from infected to normal guinea-pigs by feeding ticks first on the infected and then on the normal animals. He found out that the capacity to infect is transmitted to the eggs and larvae of ticks. Dr. Luis Salles Gomes produced experimental typhus in guinea-pigs by inoculating them with ticks captured near the homes of typhous patients. The clinical observations of the speakers confirming experimental work previously reported indicate that ticks are a common transmitting agent of exanthematous typhus. The prevention of typhus in São Paulo is difficult because of the abundance of ticks in rural areas.

Serology of Leprosy

Drs. O. G. Bier and Kate Arnold, in a lecture before the Sociedade de Biologia of São Paulo, reported their studies on the specificity of the Rubino test in leprosy. They examined 327 samples of serums. The proportion of positive tests in the different forms of leprosy was as follows: pure nervous leprosy, 29.4 per cent; maculo-anesthetic leprosy, 41.7 per cent; mixed form, 56.5 per cent; tubercular form, 66.6 per cent; incipient cases, 13.8 per cent. Only one positive test was obtained from the study of 945 control serums. In mixed forms, the specificity of the test varies with the intensity of the cutaneous symptoms without any apparent relation to the nervous component. These studies confirm the statements of Rubino, Marchoux and Caro on the necessity of electrolytes for the agglutination and on the exclusive absorption of leprosy agglutinins by a suspension of globules in formaldehyde.

Changes in Finger Prints of Lepers

Dr. Leonidio Ribeiro has published articles on the changes that leprosy causes on the designs in finger prints of lepers. He has made studies on this subject in the hospitals of the colony for lepers in Curupaty, Jacarépaguá, Rio de Janeiro. The author says that Locard observed white streaks in the finger prints of normal persons in 10 per cent of the cases. Ribeiro found white lines in the finger prints of lepers in 70 per cent of the cases. He concludes that leprosy causes marked changes in the designs of the finger prints.

Typing of Blood of Indians

Drs. Leonidio Ribeiro, W. Berardinelli and M. Roiter recently made determinations of the blood groups in 100 Guarani Indians of Colonia em Missões, Rio Grande do Sul. In all of them the blood group was of the O type. Snyder observed that 91.3 per cent of pure American Indians belonged to the O type. Vela found 95.5 per cent of Ecuadorian Indians of the O type. The authors pointed out the ethno-anthropological importance of the subject and emphasized the fact that there is a predominance of the group of the O type among pure Indians living in isolated colonies.

Marriages

JUNIUS ALBION GILES JR., Chapel Hill, N. C., to Mrs. Mary Tatnall Warner Carpenter of Wilmington, Del., May 24

ROBERT KEMP WILSON, Providence, R. I., to Miss Louise Margaret Nelson of Fall River, Mass., June 3

WINFIELD SCOTT FARMER, Nashville, Tenn., to Miss Ollie McGinness of Carthage, at Spartan, May 4

RUSKIN GREGORY ANDERSON, Spartanburg, S. C., to Miss Corryne Haskell in Atlanta, Ga., May 25

TRYGGVE ALEXANDER HACERUP, Dodgeville, Wis., to Miss Ingrid Holmboe of Chicago, May 4

JOHN ALFRED MOFFITT to Miss Lila Lee Brown both of Oklahoma City, at Tulsa, May 5

CARL VANN TYNER, Lenkesville, N. C., to Miss Charlotte Brown of Chapel Hill, June 2

SOLOMON J. TUREL, New York, to Miss Rose Lillian Albert of Newark, N. J., June 2

ANDREW F. BULFER, Chicago, to Miss Julia Sawyer of DuQuoin, Ill., April 24

RICHARD B. EASLEY, Huntington, W. Va., to Miss Mary F. Kellam, April 30

Deaths

Philip William Nathan of New York, University of the City of New York Medical Department, 1893, member of the American Orthopedic Association and fellow of the American College of Surgeons, at one time clinical professor of orthopedic surgery, University and Bellevue Hospital Medical College, veteran of the Spanish-American and World wars, aged 62, at various times on the staffs of the New York Society for the Relief of the Ruptured and Crippled, Beth Israel Hospital, New York Infirmary for Women and Children, Montefiore Hospital for Chronic Diseases and the Mount Sinai Hospital, where he died, April 20, of carcinoma of the pancreas

John Earl Elise, Portland, Ore., Northwestern University Medical School, Chicago, 1905, member of the Oregon State Medical Society, the North Pacific Surgical Association and the Pacific Coast Surgical Association, past president of the Pacific Northwest Medical Association and the Portland Academy of Medicine, fellow of the American College of Surgeons, emeritus professor of surgery, University of Oregon Medical School, formerly chief of the surgical service of the Multnomah County Hospital and the Doernbecher Memorial Hospital for Children, aged 56, died, May 3, of cardiovascular renal disease

Frank Dyer Sanger, Ruxton, Md., College of Physicians and Surgeons, Baltimore, 1888, member of the Medical and Surgical Faculty of Maryland, professor emeritus of rhinology and laryngology, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, fellow of the American College of Surgeons, consulting laryngologist to the Mercy, Sydenham, Bay View, Bon Secours and Union Memorial hospitals, the Church Home and Infirmary and the Hospital for Women, Baltimore, aged 70, died, May 15

Robert Carroll Howard of New York, Cornell University Medical College, New York, 1911, clinical professor of otology, New York Polyclinic Medical School and Hospital, member of the American Laryngological, Rhinological and Otological Society, fellow of the American College of Surgeons, associate attending otologist to the New York Polyclinic Medical School and Hospital, consulting otolaryngologist to St. Elizabeth's Hospital, aged 51, was found dead, May 5, of angina pectoris

Edward Arthur Parker, Brooklyn, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890, member of the Medical Society of the State of New York, at various times on the staffs of the Williamsburgh Maternity Hospital, St. Mary's Hospital and the Brooklyn Eye and Ear Hospital, aged 66, died, May 17, of coronary thrombosis

Mark Jampolis of Chicago, Northwestern University Medical School, Chicago, 1906, member of the American Academy of Pediatrics, associate in pediatrics at his alma mater, aged 33, on the staffs of the Sarah Morris Hospital for Children, the La Rabida Sanitarium and the Michael Reese Hospital, where he died, May 19, of mesenteric thrombosis

Marion Sparehawk Jordan of Clinton, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901, past president and secretary of the Clinton County Medical Society, on the staff of the Jane Lamb Memorial Hospital, aged 68, was found dead in bed, April 30, of coronary heart disease

Donald J. O'Connor, Appleton, Wis., Detroit College of Medicine, 1897, during the World War was a member of the Volunteer Service Corps, chief surgeon and consultant of the U. S. Public Health Service, for many years on the staff of St. Elizabeth Hospital, aged 60, died, May 4, of myocarditis and coronary thrombosis

Daniel Joseph McCarthy, Bridgeport, Conn., College of Physicians and Surgeons, Baltimore, 1906, member of the Connecticut State Medical Society, fellow of the American College of Surgeons, aged 52, on the staff of St. Vincent's Hospital, where he died, April 23, of lobar pneumonia, chronic endocarditis and gastric ulcer

Cornelius A. M. Dorrestein of New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1897, senior chief of the gynecological staff, Touro Infirmary, and chairman of the Radium Institute, on the staff of the Charity Hospital, aged 61, died April 16, of heart disease

George Harris Searcy, Tuscaloosa, Ala., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901, member of the Medical Association of the State of Alabama, aged 58, died, May 6, in the Veterans Administration Facility of hemorrhagic meningoencephalitis

Edward Jones Wannamaker, Orangeburg, S. C., University of the City of New York Medical Department, 1888, member of the South Carolina Medical Association, veteran of the Spanish-American War, aged 68, died, May 7, in a hospital at Charleston, of chronic myocarditis

Edmund James Boardman, Winnipeg, Manit., Canada, Manitoba Medical College, Winnipeg, 1907, assistant professor of clinical surgery (urology) at his alma mater, past president of the Manitoba Medical Association, aged 57, died, May 12, in Saskatoon, Sask., of angina pectoris

Frank White, Philadelphia, Jefferson Medical College of Philadelphia, 1891, member of the Medical Society of the State of Pennsylvania, formerly on the staff of the American Hospital for Diseases of the Stomach, aged 64, died, March 27, of heart disease

Harold Mark Akey, Merrill, Wis., Marquette University School of Medicine, Milwaukee, 1932, member of the State Medical Society of Wisconsin, aged 27, on the staff of the Holy Cross Hospital, where he died, April 30, of cerebral hemorrhage

Henry William Dueringer of Oak Park, Ill., Chicago Homeopathic Medical College 1896, served during the World War at one time on the staffs of St. Joseph's and Sherman hospitals, Elgin, aged 66, died, May 20, of chronic myocarditis

Albert Harter Lane of Dayton, Ohio, Louisville (Ky.) Medical College, 1894, past president of the Montgomery County Medical Society, formerly health commissioner of Dayton, aged 77, died, May 5, of cerebral hemorrhage

David Dale of Bellefonte, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1904, served during the World War, on the staff of the Centre County Hospital, aged 59, died, April 22, of cerebral hemorrhage

John C. Joiner, Honey Grove, Texas, University of Louisville (Ky.) School of Medicine, 1892, member of the State Medical Association of Texas, health officer of Honey Grove, aged 65, died, April 20, of hemiplegia

Frederick Foster Dowds, Mount Vernon, Ohio, Western Reserve University Medical Department, Cleveland, 1912, member of the Ohio State Medical Association, aged 52, died, April 30, of cerebral hemorrhage

Albert Leroy Doe, Long Beach, Calif., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, aged 54, died, March 31, of cerebral hemorrhage and arteriosclerosis

Reginald Arthur Yeld, Edgewood, B. C., Canada, M.B., in 1898 University of Cambridge Faculty of Medicine, Cambridge, England, and M.D., in 1901, aged 61, died, April 3, of lobar pneumonia and influenza

Howard Elmer Campbell of Anita, Iowa, University of the City of New York Medical Department, 1891, past president of the Cass County Medical Society, aged 71, died, April 23, of aplastic anemia

John McGuire, Staten Island, N. Y., College of Physicians and Surgeons of Chicago, 1890, aged 74, died, April 9, in the Sailor's Snug Harbor Hospital, of cerebral thrombosis and chronic myocarditis

James W. Fox, Hillsdale, N. J., New York Homeopathic Medical College and Hospital, New York 1904, member of the Medical Society of New Jersey, aged 62, died, May 2, of diabetes mellitus

Vivian Salisbury Way Worden, Saranac Lake, N. Y., Syracuse University College of Medicine, 1919, member of the American Psychiatric Association, aged 43, died, May 7, of heart disease

Edward Thomas Kelty, Tiptonville, Tenn., University of Nashville Medical Department, 1900, member of the Tennessee State Medical Association, aged 61, died, March 30, of heart disease.

Fern A. Rice, Delavan, Wis., Bennett College of Eclectic Medicine and Surgery, Chicago, 1889, for many years city health officer, aged 66, died, April 22, of heart disease

Della Priscilla Pierce, Kalamazoo, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1890, aged 81, died, May 9, of arteriosclerosis

Howard Wallace Stuch, Allegan, Mich., University of Virginia Department of Medicine, Charlottesville, 1901, aged 58, died, April 26, of organic heart disease

Harris Taylor Collier, McKenzie, Tenn., Tulane University of Louisiana Medical Department, New Orleans 1900, aged 58, died, May 4, of cerebral hemorrhage.

Daniel D. O'Gorman, St. Louis, Trinity Medical College, Toronto, Ont., Canada, 1888, aged 70, died, April 27, in St. John's Hospital, of coronary thrombosis

Charles A. Sellers, Hartford City, Ind., Fort Wayne College of Medicine, 1904, aged 60, died, April 27, of chronic nephritis, hypertension and cerebral edema

Roger Eustace Bousfield, Ellsworth, Maine, Boston University School of Medicine, 1931, aged 33, died, March 20, of diabetes mellitus and chronic myocarditis

William Cathey Harkey, Lenexa, Kan., University Medical College of Kansas City (Mo.), 1900, aged 63, died February 7, of carcinoma of the stomach

William Harvey DeKay, Hurleyville, N. Y., University of Buffalo School of Medicine, 1875, aged 86, died, March 31, of angina pectoris and arteriosclerosis

Luther Walton White, San Antonio, Texas, University of Arkansas School of Medicine, Little Rock, 1909, aged 52, died March 9, of cerebral hemorrhage.

Rollen Lemuel Shunaberry, Scranton, Pa., Jefferson Medical College of Philadelphia, 1910, aged 47, died suddenly May 17, of heart disease

Grafton D. Whitaker, Kansas City, Kan., Cincinnati College of Medicine and Surgery, 1870, aged 85, died, April 4, of coronary thrombosis

Harry Aloysius Doherty, Atlantic City, N. J., Jefferson Medical College of Philadelphia, 1906, aged 62, died April 14, of coronary occlusion

George Henry Ramsey, Victoria, B. C., Canada University of Toronto (Ont.) Faculty of Medicine, 1899, aged 71, died, February 22

Samuel Pool, Leakesville, Miss. (licensed in Mississippi in 1901), formerly county health officer, aged 78, died, April 13, of hepatic disease.

George Willford Wood, Wilmington, Ohio, Homeopathic Hospital College, Cleveland, 1886, aged 78, died, April 1, of pneumonia

Alburton Alonzo Dewey, Bristol, Conn., Eclectic Medical Institute, Cincinnati, 1906, aged 60, died, March 16, of coronary occlusion

Rephaniah Neville, Mishawaka, Ind. (licensed in Indiana in 1897), Civil War veteran, aged 88, died, April 5, of arteriosclerosis

Milton V. Dewire, Sharon, Wis., Rush Medical College, Chicago, 1894, aged 67, died, May 6, of myocarditis and arteriosclerosis

Daniel V. Ray, Rossville, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1892, aged 69, died, April 9, of heart disease.

Edwin Coleman Brown, Boston, College of Physicians and Surgeons, Boston, 1894, aged 65, died, April 28, of heart disease.

Burch C. West, Richburg, N. Y., University of Pennsylvania Department of Medicine, Philadelphia 1906, aged 55, died, March 22, of colitis

Ham S. Hampton, Tampa, Fla., Hospital Medical College Atlanta, Ga., 1910, aged 47, died March 31, of pneumonia

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

NORMAL BLOOD PRESSURE

To the Editor—If convenient please answer the following question: Which is the more correct generalization that the normal blood pressure reading should be 100 mm. plus the age of the individual or that it should be 90 mm. plus the age of the individual?

JOHN H. PREWITT (third year student), Lexington, Ky.

ANSWER—Although the generalizations cited have been popular for many years, neither is correct. What is considered normal is, after all, merely the mean or average of the readings in presumably healthy persons. Thus, as with other "normal" measurements, such as height or weight, the normal falls within a range and is not a single set figure. Age is by no means the only physiologic factor that causes variation of the normal arterial tension; physique, sex, race and climate are persistent factors, and emotions, physical activity, fever, anesthesia, environmental temperature and posture affect the arterial tension transiently without necessarily passing beyond normal limits. The systolic tension is far more labile and variable than the diastolic tension, thus, standards of normality are better fixed by the diastolic than by the systolic pressure.

The average or mean readings for the systolic tension do not increase as rapidly as age. Thus any such rule as mentioned in the query will prove unsatisfactory. The most extensive and accurately determined averages of normal are those prepared for and by life insurance underwriters. The following table reveals the normal averages for white males in the United States; the normal range should include readings 10 mm. in either direction than these averages for the systolic tension and 5 mm. higher and 10 mm. lower than the mean for the diastolic tension.

Average Normal Arterial Tension, in Relation to Age, in White Males

Age	Systolic	Diastolic
20	120	79
25	121	80
30	122	81
35	123	82
40	125	83
45	127	84
50	129	85
55	131	86
60	134	87
65	138	89

It is notable that with advancing years the average normal systolic tension increased more rapidly than the diastolic pressure, but much more slowly than the age. The normal pulse pressure increases from 41 mm. at 20 years to 49 mm. at 65 years.

If a reasonably accurate simple generalization is desired the following rule is justified. In normal adults the normal range of the blood pressure is 110-148/70-95 approaching the upper limits in the older age groups. An arterial tension over 150 systolic and/or 100 diastolic is abnormally high. Isolated observations of hypertension, however, do not constitute valid evidence of hypertensive disease because of the many physiologic variables that may alter the tension temporarily.

CONTAGIOUSNESS OF SYPHILIS

To the Editor—A patient came to me recently with a tertiary syphilitic cutaneous lesion. The history is vague concerning any initial lesion. Treatment consisted of six courses of arsenic acid and a heavy metal with iodides over a period of two years. The patient is a woman beyond the menopause—free from any evidence of syphilis at present—beyond a positive Wassermann the cutaneous lesions having disappeared. The spinal fluid is completely negative. Is it permissible for the patient to marry which she desires or to have intercourse if she is free of any contagious lesion? Kindly omit name.

M. D. New York

ANSWER—It is not clear exactly what is meant by "six courses of arsenic acid." Supposing that this is one of the effective arsphenamines, both the stage of the patient's infection and the treatment given provide as much assurance as there is that she is noninfectious and may marry or have intercourse without the likelihood of transmitting the disease. Absolute and unqualified statements on such a matter while the Wassermann test of the patient's blood is positive cannot be made, and the marital or sexual partner may properly expect to be made acquainted with the situation however remote the risk.

MASTURBATION IN GIRLS

To the Editor—A girl aged 8 years (whose parents are of middle class and sufficiently intelligent to deplore her affliction), has practiced masturbation since the age of 1 year (according to the mother). As near as I can ascertain, four operations have been performed at various times between 14 months of age and a year ago for what I judge has been separation of the prepuce from the clitoris, especially since on examination, there is considerable scarring in that area with the clitoris completely bound down and out of possible vision. No operative procedure has ever given results. Up to three months ago the child was a constant leader in her school work. At that time and for the first time she had started her practices in the schoolroom until it was necessary to remove her from school. Also at that time her grades in school started on a gradual decline and she has gradually developed a facial expression approaching mild idiocy. She is entirely cooperative at home in attempting to help correct the habit allowing the mother to tie her hands to the bedposts at night without complaint or remonstrance. This was done by the latter as a last desperate measure to correct the condition. The mother also states that an orgasm takes place as a condition of rigidity and muscular spasm terminates the act. Any information as to treatment and prognosis that I may pass on to these parents will be greatly appreciated. Intestinal parasites as a causative agent have been excluded. Please omit name and town if published.

MD Nebraska

ANSWER.—Masturbation in infants and young girls is generally started by some local irritation and, when this irritation has been removed before the habit has become definitely fixed the habit will be as a rule abandoned. The longer one waits, however, the more fixed the habit becomes, the child notes the pleasurable sensation accompanying the act, and the more difficult it is to cure it. In this case it was certainly not good treatment to perform a series of operations on the genitals as this procedure more definitely fixes the attention of the child on the genital organs. Whatever treatment is adopted, the most important thing to remember is to divert the child's attention from these organs. For this reason all restraining apparatus should be avoided, as these constantly keep the child's attention fixed on the habit. At school or in the gymnasium any exercises that tend to produce friction on the parts should be avoided, such as sliding down a pole or sliding on a banister. In doing this, however, the child should not be told to avoid these exercises, but it should be so arranged that she does not get them. In other words, nothing should be said or done that directs the child's attention to the habit. Spanking must be avoided, as in some children this act arouses erotic sensations.

It would be well if possible to avoid all reference to the condition, even if the parents know that the child is masturbating. One should not let the child know that she is being watched. She should avoid tea and coffee and, of course alcoholic beverages. She must avoid all sensual movies without, however, knowing that this is done on purpose. For a short time the internal administration of bromides in proper doses is of value, but the most important measure is to replace some other activity for the masturbation. Any outdoor hobby, such as swimming, golfing or tennis is of value. Nothing is so good as hard work so as to keep the child occupied. Any inclination of the child to be by herself should be tactfully discouraged. In the vast majority of cases the foregoing outline will cure the child. Should the psychic element be found to predominate psychoanalysis by an expert medical psychoanalyst would be in order.

TRAUMA AND HERNIA

To the Editor—I have a patient who was struck by an automobile and rendered unconscious for eight hours. Surface injuries were trivial. He emerged from the accident however, with bilateral direct inguinal hernias—rather large abdominal openings—more like a splitting open of the inguinal canals. He is positive he had no hernia before. Can a person receive bilateral hernias from a trauma like this? Are there any cases in the literature? Where can I get further information on this subject? If published please use initials.

MD New York

ANSWER.—J. J. Moorhead (Traumatic Surgery, ed 2, Philadelphia W. B. Saunders Company, Relation of Trauma to Hernia, *New England J Med* 209 568 [Sept. 21] 1933) states that trauma alone is the rarest cause of hernia and that they are never bilateral. Bull and Coley (quoted by Moorhead) investigated the alleged relation of injury to hernia in 10,000 cases and they regarded two as due to direct violence. C. D. Selby (Direct Abdominal Hernia of Traumatic Origin, *THE JOURNAL*, Nov 3, 1906, p 1495) reported a case of direct hernia following a direct injury. Operation disclosed a tear in the external oblique fascia, the internal oblique and the transversalis muscles.

Direct hernia, which occurs only from 3 to 5 per cent as frequently as the indirect type, is more likely to be due to trauma (Moorhead).

Watson (Hernia, St. Louis, C. V. Mosby Company, pp 603-613) gives a good review of the compensation boards. In some

courts proof must be furnished that the hernia did not exist prior to the accident in a claim for traumatic hernia. However some compensation boards rule that when a strain causes protrusion of the bowels it is a compensable injury even though the protrusion is at a point weakened by congenital malformation or preexisting hernia.

Gorton (Compensable Hernia, *J Indiana M A* 23 521 [Nov.] 1930) states that if a hernia develops as an incident to the man's daily work it should be considered a result of a special anatomic weakness for which the company is in no way responsible. He considers that industrial accidents of various sorts usually lifting or straining, are regarded more frequently as the cause of hernia than the facts warrant, but that many of these industrial accidents are the exciting cause.

The consensus is that there is a preformed sac or a congenital weakness in almost all cases.

A number of factors must be considered in determining what relation if any, an accident bears to the development or aggravation of a hernia. These are the history of the accident, the time intervening, the location and extent of the trauma, the type and degree of hernia, and the evidence of local injury.

There is enlargement of the external abdominal ring in 2.2 per cent of men, according to the surgeon general's report from the examination of 2,000,000 drafted men. Erdman (Nelson Loose-Leaf Surgery, New York Thomas Nelson & Sons 4 610) thinks that this enlargement may be an important determining factor in the occurrence of primary direct hernia.

The following references will give further information.

CORD BLADDER—CHRONIC CYSTITIS

To the Editor—1 What is string or cord bladder? How can I get information about care and treatment? 2 In cases of chronic cystitis coming on after prostatectomy and having a duration of some years what would be the probable changes leading to death? Can I get advice as to treatment? 3 Mountain Valley water from Hot Springs Ark is advertised to neutralize acids that cause irritation. Would this be better than sodium carbonate? 4 One good textbook advises potassium chlorate also a milk diet. My experience with milk is that it causes retention and pain and has to be dropped. Can I get an opinion as to these two substances?

EVERETT FLOOD MD Friendship Maine.

ANSWER.—1 So-called cord bladder is a condition caused by paralysis of the nerves supplying the bladder and is characterized by an atonic condition of the detrusor muscles a variable degree of residual urine, and relaxation of the internal sphincter and prostatic urethra. There is a great difference in treatment of the bladder that is completely paralyzed, as frequently occurs with severe spinal trauma, or only partially, as is often observed with various types of disease involving the spinal cord. Employment of catheter drainage is contraindicated in the former group but is usually advisable in the latter.

A number of articles have been written in regard to the treatment of cord bladder among which may be mentioned

Cumming, R. E. Bladder Paralysis. Etiology Prognosis and Treatment *J Michigan M Soc* 28 5 (Jan.) 1929
Braasch W F Data with Regard to Lesions of the Nerves of the Urinary Tract, *J Urol* 13 383 (April) 1925
Canik J R, and Greditzer H G Observations on the Bladder in Diseases of the Central Nervous System *Am J Syph* 1 42 (Jan.) 1917
Corbus B C and O'Connor V J Tabetic Bladder from the Stand point of the Urologist *THE JOURNAL*, Nov. 18 1922 p 1750
Braasch W F and Thompson G J Treatment of the Atonic Bladder *Surg Gynec & Obst* to be published

2 Chronic cystitis persisting after prostatectomy is often secondary to renal infection, although in many cases it results from a persisting infection in that portion of the prostatic urethra from which the prostate has been enucleated. Although the symptoms of such infection may be trying, it is seldom that it is a major factor in causing a patient's death. However, in case of severe increasing infection leading to pyonephrosis, fatal complications may follow, although this occurs in only a small percentage of cases. The treatment of postoperative cystitis should consist of first determining the type of infection. If bacilluria is present it can be overcome frequently by the ketogenic diet, together with acidification of the urine by some drug such as ammonium chloride or ammonium nitrate. Topical applications to the prostatic urethra and lavage of the bladder with solutions of potassium permanganate, acriflavine, or weak Goulay's solution will be of value in many cases.

3 It is a common fallacy that the reaction of the urine with chronic cystitis is acid and that this is the cause of irritation. Symptoms are almost always due to an inflammatory condition of the mucosa and not to any variation in the degree of acidity of the urine. If alkalization of the urine causes subjective relief,

it is best accomplished by means of some drug such as sodium bicarbonate rather than by attempting to bring it about with any type of water

4 It is open to question whether any drug or milk diet will be of much benefit in chronic infections of the bladder. The best methods of treatment are those described above.

ALLERGIC REACTION FROM TOXOID

To the Editor—In an answer to a recent query (*THE JOURNAL* January 5, p. 68) concerning the probable relationship between an allergic reaction resulting from the administration of alum precipitated toxoid and a previous inoculation with pertussis vaccine it is inferred that the patient was sensitized by the vaccine. Further it is assumed that the blood proteins (probably other than those of human blood although this fact is not definitely established) which may have been contained in the vaccine were the responsible antigenic substances. In order to explain the allergic response which is believed to have resulted from the subsequent injection of alum precipitated toxoid it is not necessary to assume that these two biologicals contained proteins from the same source? As far as I am aware pertussis vaccine is prepared from organisms grown on Bordet medium that has been enriched by the addition of either defibrinated human blood or defibrinated sheep blood. It is possible of course that in spite of the washings to which it is subjected during its preparation the final product might have contained small amounts of the blood. The alum precipitated toxoid as is known does not contain serum in the same sense as the older toxin-antitoxin mixtures contained serum. It may however contain small amounts of those proteins derived from the meat usually veal employed in the preparation of the nutrient broth in which the diphtheria organisms are grown. In the absence of definite information as to the nature of the proteins that may have been responsible for the effect observed the conclusions stated in the answer seem to be unwarranted. Please omit name.

M D Ohio

ANSWER—Shortly after the answer to the query was prepared, an unusual (allergic) reaction following a Schick test came to notice. This reaction bore such a close resemblance to the reaction following the alum toxoid injection that it now seems quite unlikely that the preceding pertussis vaccine injection had anything to do with the reaction that followed the alum toxoid injection. Although many thousands of Schick tests had been done in the department concerned, this was the first time that an allergic reaction had followed a Schick test. It had to be controlled with epinephrine. Since no vaccine injection had preceded the Schick test, it now seems reasonable to assume that in exceptional instances alum toxoid might elicit an allergic reaction. The cause of such reactions is not known.

USE OF DIGITALIS POSTOPERATIVELY

To the Editor—What is the modern theory with regard to the use of digitalis in other than physiologic doses? It is apparently quite common for the older practitioners in this locality to give digitalis in doses of from 1 to 3 grains (0.065 to 0.2 Gm.) of the powdered leaf in cases of mild cardiac insufficiency commonly observed in old patients postoperatively. Is there any reason to suppose that such doses exert any effect on the heart muscle? I have recently seen a 75 year old man three days after operation with a temperature of 102 and the pulse 130 but regular. The blood pressure was 130 systolic 90 diastolic. Physical examination of the chest showed numerous coarse rales throughout. Medication consisted of $7\frac{1}{2}$ grains (0.5 Gm.) of caffeine every four hours one-thirtieth grain (0.002 Gm.) of strychnine every four hours and 1 cat unit of digitalis subcutaneously every six hours for four doses. Kindly criticize such treatment. Please omit name.

M D Arizona

ANSWER—The routine administration of digitalis postoperatively is often practiced, but so far adequate evidence is lacking to prove definitely that such empirical use is really rational or beneficial. Elderly patients without previous congestive failure do not develop heart failure immediately following operation. If circulatory complication develops, it usually consists in varying degrees of failure of the peripheral circulation. In this condition digitalis is not beneficial so far as we know. If there should be true myocardial failure as manifested by pulmonary or peripheral congestive failure following operation, digitalis is indicated. It is doubtful, however whether such small doses as from 0.065 to 0.2 Gm. of powdered leaf administered daily will have any appreciable effect, because this dose is close to the amount eliminated from the human body and hence accumulation would not occur or would develop very slowly. It is recognized on the other hand that considerably smaller amounts of digitalis than those advocated in recent years can improve the failing heart.

In this specific case, digitalis was given in four doses of 0.1 Gm. each of a standard preparation. Such an amount is insufficient to induce with certainty beneficial results in a heart that is failing provided the patient's heart is capable of responding to digitalis. Experience shows that not every instance of heart failure particularly with regular rhythm

responds favorably. As far as additional medication such as caffeine and strychnine, is concerned, the beneficial effect would be on the peripheral circulation. If evidence of circulatory collapse is present, such medication is often beneficial. The routine use of digitalis, caffeine and strychnine postoperatively as a preventive of either myocardial or peripheral circulatory failure is not rational.

Fever and rapid pulse developing postoperatively are usually associated primarily with changes in the peripheral circulation. The level of the blood pressure does not rule out the existence of such a condition as the pressure may previously have been higher. The coarse rales in the lungs may be the result of infection, or of failure of the myocardium. The administration of caffeine and strychnine is therefore rational. If the correspondent believes that the pulmonary signs developed as a result of failure of the heart more prolonged digitalis therapy than that given is also in order.

HEARING WATCH TICK AND WHISPERED VOICE

To the Editor—Will you kindly give me the interpretation of the following. A patient is not able to hear the tick of a watch at a distance of 2 feet but is able to hear a whispered voice at a distance of 20 feet.

V W JENSEN M.D., Shelby Mich.

ANSWER—The tick of certain watches is extremely faint. Furthermore, the sounds produced by watches are in the nature of noises, and it is quite possible that the pitches of some of these sounds is much higher than those of the ordinary whispered voice. Therefore, if the individual had an impairment of hearing for the high tones he might hear the middle tones of the whispered voice but not those of the watch tick. It is also essential to know whether the opposite ear was tightly closed while the ear was being tested with the whispered voice, otherwise the sounds may be carried through the air to the normal ear and heard at a great distance. One should remember that noises are sounds produced by irregular vibrations and not like those of pure tones, which consist of regular even vibrations.

PHLEBITIS AFTER INJECTION OF VARICOSE VEIN

To the Editor—Following an injection of 3 cc. of sodium morrhuate into a varicose vein on the anterior aspect of the middle third of the leg a woman was confined to bed for a month because of pain on walking. Relief from pain is obtained by rest, elevation of the limb and ice bags. The injected vein for about 3 inches is prominent and very tender to touch. The reaction is confined to the vein and not to the perivenous tissues. The patient is still confined to bed. What can be done to make her ambulant? The deep veins are patent. Please omit name.

M D New York

ANSWER—From the description the case is that of an induced phlebitis which often follows an injection into a vein harboring a latent infection. It is often difficult to diagnose a latent infection before the injection but when the vein is tender and hard, if the temperature of the skin is slightly elevated or if the patient complains of feeling changes of weather in the affected area the diagnosis of a latent infection is probable. Such veins may respond with a marked tubular phlebitis even after a simple puncture. Should the deep vein be patent there is no reason to keep the patient confined in bed. An Unna's boot relieves the pain readily so that the patient may be up and around without much discomfort. If the phlebitis is spreading upward and shows no tendency to quiescence, a high saphenous ligation may be done to prevent further ascension of the clot and to remove increased pressure from the inflamed vein. Occasionally the severe pain is due to a direct involvement of the saphenous nerve in which case the nerve might have to be sectioned at a higher level to relieve pain. A mild dose of x-rays over the inflamed area not exceeding 100 roentgens, is often helpful.

AUTOGRAFTS IN BURNS

To the Editor—We have a patient in our hospital who had a very extensive burn. We have grafted him a number of times but as yet do not have complete coverage. The skin area available on his own body is practically exhausted and we shall be forced to look elsewhere for grafts. The patient is one of a set of twins and we should like to know whether a graft from his twin brother would be more valuable than a true heterogenous graft.

HARRY C. DeBOURCY M.D. Davenport Iowa

ANSWER—Autografts are by far the most uniformly successful, but if these are not available members of the patient's immediate family particularly those of the same blood group should prove the most satisfactory donors of skin. The twin brother if he is of the same blood group as the patient, should prove satisfactory but probably not more so than other brothers or sisters who are of the same group.

DACRYOCYSTITIS AFTER OPERATION FOR
NASAL POLYPS

To the Editor—I have under my care at present a man who had a rather marked epiphora shortly after an operation for the removal of nasal polyps. At the present time he is suffering from an acute dacryocystitis. I should like your opinion as to whether or not an attempt should be made to open the intranasal end of the tear duct or whether because of the acute dacryocystitis an extirpation of the lacrimal sac should be done after the infection has subsided. Then again is there any explanation as to why excision of the sac diminishes the tearing? Kindly omit name
M D New Jersey

ANSWER.—It is possible that the nasal operation injured the mucosa at the nasolacrimal opening and partially or completely occluded the passage. If only an edema had been present, the epiphora should have disappeared in ten days. It is possible for the infection to have involved the tear sac, or that the sac infection may have been incidental. We do not advise probing during the acute dacryocystitis. Application of heat until the infection clears is the best treatment. If a large abscess is present, it should be incised. The West or Tott-West operation is done in these cases to make an enlarged permanent opening between the tear sac and the nose. If the sac is removed, the epiphora remains unless a sinus forms between the punctum and the nose, but this is not the rule.

ACTION OF PHYSOSTIGMINE ON PUPIL

To the Editor—Would you please advise me as to whether or not physostigmine when contracting the pupil exerts any action on either the ciliary circular muscular fibers or the longitudinal? If so, which? Please omit name
M D Ohio

ANSWER.—In his Text Book of Ophthalmology (1535) Duke Elder writes "Eserine [physostigmine] instilled into the conjunctival sac brings about a miosis and a spasm of accommodation, which commence in a few minutes and reach a maximum in about thirty minutes. The effect on the ciliary muscle wears off in about two hours but for some considerable time thereafter the accommodation remains in a hyperexcitable state, so that the slightest voluntary effort throws it into a strong spasm." The miosis lasts longer, from twelve to fourteen hours. Physostigmine stimulates the oculomotor end apparatus. The circular, meridional and radial fibers are affected. Contraction of the last two produces a pull on the choroid and indirectly on the retina, while all fibers take part in opening the canal of Schlemm. On page 61 of his book Duke Elder likens the ciliary muscle under physostigmine to that of the muscle of a hyperopic eye as compared with that of the normal or emmetropic eye.

NO ADDED VALUE TO MENTHOLATED CIGARETS
FOR ASTHMATIC PATIENTS

To the Editor—Please give me the general consensus as to whether mentholated cigarettes as compared to other cigarettes are beneficial or harmful to a smoker with an irritable throat or a tendency to asthmatic bronchitis
M D Pleasantville N J

ANSWER.—There is no definite answer as to the question of the relative good or bad resulting to a smoker from using the various kinds of mentholated and nonmentholated cigarettes.

In a personal communication Yandell Henderson, working in the Laboratory of Applied Physiology at Yale University writes "Investigations which we have carried out show that menthol in cigarettes is entirely without harmful effect. Aside from the cool sensation, mentholated cigarettes are in no respect different from any other."

In general, it might be said that if people with sensitive throats or with a tendency to bronchial asthma or asthmatic bronchitis must smoke they will find little difference in the results from mentholated or nonmentholated cigarettes.

SCIATICA

To the Editor—Will you kindly tell me whether you consider sciatica primary or secondary when due to diabetes, syphilis, focal infection, alcohol and arsenic? Kindly omit name
M D Indiana

ANSWER.—Sciatica as a prominent symptom can scarcely be spoken of as primary or secondary. The term sciatica signifies a pain along the course of the sciatic nerve and this may be produced by processes either intrinsic or extrinsic to the nerve. Diabetes, syphilis, focal infection, alcohol and arsenic produce intrinsic changes and give signs of a sciatic neuritis.

Pelvic tumors and arthritis of the spine or sacrum affect the nerve extrinsically by distortion or tension and the pain thus induced is usually designated as sciatica.

Book Notices

What You Should Know About Heart Disease By Harold E B Pardee M.D. Assistant Professor of Clinical Medicine Cornell University Medical School. Second edition. Cloth Price \$1.50. Pp 127 with 4 illustrations. Philadelphia Lea & Febiger 1935.

This was written to help the heart patient to understand his condition. "The better he is able to do this the better he will be able to aid in his own cure by cooperating with the physician who is trying to correct the unpleasant result of the disease." The text is well printed and durably bound. Technical language, in the main, is successfully avoided. Only four explanatory diagrams are employed and the book lacks an index. The first chapter is devoted to the anatomy and physiology of the heart and circulation. The second chapter is a discussion of the causes of heart disease and an explanation of the resultant pathologic changes. Arteriosclerosis, rheumatic fever, syphilis, goiter, lead, alcohol, diabetes and hypertension are included. It is the author's view that tobacco as a cause of heart problems is much maligned. It will disappoint many readers that only a short paragraph is devoted to the nervous heart. The symptoms of heart disease are discussed in detail and the cardiac irregularities and murmurs are explained. The fifth chapter is devoted to prognosis and the next four chapters contain a discussion of methods of treatment. Special attention is given to the treatment of the causative factors, and detailed instructions are given concerning dietary management. Drug therapy includes a discussion of mercury, digitalis and glyceryl trinitrate. The theobromine derivatives, mercurial diuretics and opiates are omitted. The need of recreation is discussed and the advantages of southern climate in rheumatic disease are noted. One chapter is devoted to the selection of occupation by cardiac patients and the problems of marriage and pregnancy. In surgical operations with anesthesia the author suggests starting the operation under chloroform and continuing with ether rather than gas anesthesia. The author clearly makes his point that proper management of a cardiac case is best obtained by full cooperation of the patient with the physician. Lack of accurate knowledge of the cardiac problem by the patient begets unreasonable fear. The book is deserving of recommendation by the physician to his cardiac patients.

A Textbook on Surgery for Students and Physicians By W. Wayne Babcock A.M. M.D. LL.D. Professor of Surgery and Clinical Surgery in the Temple University. Second edition. Cloth. Price \$10. Pp 131* with 1040 illustrations. Philadelphia & London W. B. Saunders Company 1935.

This edition shows much revision as well as new material. It is a large volume with numerous illustrations. The subject of surgery has grown to proportions demanding treatment in many-volumed systems by numerous collaborators. There remains, however, a definite need for a one volume textbook. The advantages to the student in saving of time is obvious. Babcock's book meets the ideal of economy of time without the sacrifice of quality. It is divided into four parts. The first part, on general surgery, deals with the subjects of inflammation, repair of tissues, hemorrhage, thrombosis and embolism, shock, coma and so on. The second part treats of the surgery of systems. The third part describes surgical technic. The fourth part is devoted to regional surgery. The textbook in its first edition found a wide acceptance among teachers and students. In its revised form it is abreast of the time in every chapter.

Die künstliche Zwangsflähmung bei der Behandlung der Lungentuberkulose Von Prof. Dr. Th. Naegeli Oberarzt der Chir. Univ. Klinik Bonn. A. Rh. und Dr. H. Schulte Tlgees. Chefarzt der Heilstätte Rheinland Honnorf/Rhein. Nr. 54. Tuberkulose Bibliothek. Beihefte zur Zeitschrift für Tuberkulose. Herausgegeben von Prof. Dr. Lydia Rabinowitsch. Boards. Price 7.40 marks. Pp 61 with 49 illustrations. Leipzig Johann Ambrosius Barth 1935.

This treatise systematically and thoroughly discusses the technical and clinical phases concerned with phrenic nerve surgery, considering not only the authors' idea and experiences but also the facts and opinions that have been presented by others in the extensive literature on the subject. The anatomy of the accessory branches and the communications with the sympathetic system are carefully described. Many varying views concerning the part played by the diaphragm in respiration and expectoration and the effect of paralysis on these functions are presented, which indicates that there is no universal agreement on these problems. The technic of the permanent and of the temporary operations is given in detail. The large number of surgical accidents accumulated from the literature emphasizes that the operation is not a simple one, and the late complications suggest that the procedure is not to be undertaken lightly. In considering the indications for the operation the authors quote results of many reported series of cases so that one can judge the type of case in which best results have been obtained and the groups in which less benefit has been derived. The authors feel that it is very difficult to predict in the individual case how much benefit will result, and therefore it may be well to perform a temporary operation first and later make this permanent if a prolonged paralysis seems desirable. They feel that paralysis of the diaphragm judiciously applied is of distinct value in the treatment of pulmonary tuberculosis. Forty-eight roentgenograms demonstrate excellent results following phrenic nerve interruption in the cases of pulmonary tuberculosis. A complete bibliography is given. The work can be recommended as one of the most complete presentations of this subject.

Nutrition and Physical Fitness By L. Jean Bogert Ph.D. Consultant in Nutrition. DeLuneator Institute New York. Second edition. Cloth. Price \$3. Pp 588 with 65 illustrations. Philadelphia & London W. B. Saunders Company 1935.

This useful and thoroughly practical book now appears with revisions and amplifications particularly on the subject of vitamins. The dominant trend in the book is still maintained. It is the author's purpose to show mainly how nutritional knowledge may be used intelligently in everyday life for the building of positive health. The book is well balanced and written in a simple and direct manner. The author has anticipated the reader's desire not only for theoretical information concerning nutrition but also for practical data concerning foods and their methods of preparation. The text is divided into five parts, the first three being concerned with the fundamentals. The first part deals with qualitative aspects of the diet, next how this should be supplied in terms of calories and percentage composition and, concluding this section a discussion of how this is made available to the body cells. The last two sections

are practical methods by which such information is applied in normal and special conditions. The last two parts of the book are particularly valuable, as they contain useful information not often presented in such a practical and comprehensive manner. Chapters on menu planning, economics and influences of cooking, food fads and fancies, and trends in American dietary habits are decidedly original and useful discussions. The section on diets for special conditions is clearly presented and well done. The entire book shows careful editing of the authors and timely knowledge of scientific advance in nutrition. The book is especially recommended to the nurses and students of nutrition as a well balanced, modern, critical presentation of the subject. It is too limited in scope and data, however, to serve as a single reference work for physicians.

Klinik der Erkrankungen des Herzmuskels. V. Fortbildungs-Lehrgang in Bad Nauheim 20-23. September 1934. Herausgegeben von der Vereinigung der Bad Nauheimer Ärzte. Paper. Price 10 marks. Pp. 170 with 63 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1934.

This contains a series of lectures intended for the use of post-graduate students. Various authoritative men, as Krehl, Nonnenbruch and Hochrein, have contributed. Each lecture is a unit yet the whole book gives a good statement of recent advances in the entire field. An accurate degree of emphasis is maintained throughout. Aschoff in one lecture discusses the myocardial disorders not caused by coronary disease. He places great emphasis on the myocardial injury during acute infections and its pathogenesis. The book can be read with profit by men in general practice as well as by specialists.

Medical Greek and Latin at a Glance. By Walter R. Agard, D. Litt. Professor of Greek, University of Wisconsin. With an introduction by C. H. Bunling, M.D. Professor of Pathology, University of Wisconsin. Photo-Lithoprint reproduction of author's manuscript. Paper. Price \$1.10. Pp. 42. Ann Arbor: Edwards Brothers, Inc., 1935.

There has always been a need for a handbook of useful etymological data of Greek and Latin words among most medical students and physicians. While Latin usually is part of pre-medical training, they have little experience with scientific terms. The complexity that Greek introduces for the student is often bewildering. However, such intricate terminology becomes relatively simple by learning a few principles of word construction. This handbook first presents prefixes in both Latin and Greek which are constantly encountered, then the common suffixes, and finally the principles for compounding words. A list of important medical terms derived from Greek and Latin are appended to aid the reader in seeing how compounds are formed. The book is in a sense a key to word formation and not a treatise on Greek and Latin medical terminology. As such, it serves a most useful purpose and should be the property of every medical student and physician who has not had the benefit of a classical education.

Methodik der Vitaminforschung. Von Dr. Phil. Christian Bomsdorff, Chemiker an der Universitätskinderklinik Kiel. Mit einer Einführung von Prof. Dr. med. E. Romlinger. Paper. Price 24 marks. Pp. 301 with 90 illustrations. Leipzig: Georg Thieme, 1935.

The introduction of a textbook on methods and chemistry of the vitamins should be welcomed by all workers in the field. While a book of this character will need frequent revision to meet current advances, it fills a much needed place. Too often the worker in the field of vitamin research must go through a vast amount of current literature in order to get useful data on technique. This monograph is a collection of all current methods on vitamin research. It is exceedingly well organized and edited. The text is replete with valuable protocols, illustrations and graphs, which add considerably to the text. It will be particularly valuable to the novice, as the author has included not only advanced material but such fundamental subjects as selection and care of laboratory animals, their spontaneous diseases, and the feeding of animals used for vitamin research. The author's selection of methods is excellent. When there is any doubt, alternative methods are given. While considerable advance has taken place since the chapter on vitamin C was written, it is still a valuable addition to the book and recent enough for fundamental research. A vast amount of literature, both foreign and American, has been reviewed and the reader will find the bibliography unusually complete and helpful. It is highly recommended to the novice and also the trained worker engaged in vitamin research.

Studies in Physiological Optics (Wilmer Institute). December 1928 to October 1934. Volumes I and II. Edited by C. E. Forree, Director, Research Laboratory of Physiological Optics, Wilmer Ophthalmological Institute of the Johns Hopkins University School of Medicine. [Reprints.] Paper. Various pagination with illustrations. Baltimore, 1934.

These are reprints of articles chiefly on visual fields, luminosity and adaptation of the eye to light that have appeared in the *Archives of Ophthalmology*, *American Journal of Ophthalmology*, *Bulletin of the Johns Hopkins Hospital*, *Journal of Experimental Psychology*, *Journal of General Psychology*, the *Personnel Journal*, *American Journal of Psychology*, *Transactions of the Illuminating Engineers Society*, the *Modern Hospital*, the *Notanus Schools* and the Physical and Optical Societies Report of Cambridge. The articles are by Ferree and his associates and are assembled in the order of their appearance in the various journals without any comments. The pages of the volumes are not numbered and there is no index. The volumes should more properly be called collected reprints of Ferree and his associates. They serve as a compact reprint file for one especially interested in visual field studies and lighting.

Nouveau traité de psychologie. Par Georges Dumas, professeur à la Sorbonne. Tome IV. Les fonctions et les lois générales. Avec la collaboration de Ch. Blondel, professeur à la Faculté des lettres de Strasbourg et de M. Clotui. Price 120 francs. Pp. 528 with 26 illustrations. Paris: Félix Alcan, 1934.

This volume of Alcan's monumental treatise on psychology is divided into two parts, the first dealing with the general functions of organization and the second with the general laws of mental activity. Piéron discusses attention, its evolution and mechanism, habit and memory. Association of ideas is treated by Delacroix, schematization by d'Allonnes, and symbolization by Dumas. The disrepute into which the association of ideas has fallen is reflected in the brevity of that section. In the second part of the volume Blondel points out the distinction between normal and pathologic automatism necessitated by the work of the psychiatrist de Clerambault, unfortunately recently deceased. Janet summarizes again his illuminating studies on psychologic tension and its oscillations, so neglected in these days of outrageous symbolization. The volume terminates with studies of mental activity, intellectual work, fatigue and sleep; it is better edited than the previous ones.

Elementary Human Anatomy Based on Laboratory Studies. By Katharine Sibley, Professor of Physical Education, School of Education, Syracuse University, Syracuse, New York. Cloth. Price \$4.50. Pp. 360 with 213 illustrations. New York: A. S. Barnes & Company, 1935.

This book is written from the standpoint of physical education and physical therapy. It deals especially with bones, joints and muscles and contains also brief chapters on other systems—nervous, circulatory, digestive, respiratory and the ductless glands. It represents a serious and conscientious effort to present in an orderly way such fundamental facts in the structure of the human body as would be especially interesting to students of physical education. The illustrations have been borrowed for the most part from standard works. They are well selected and instructive. The style is condensed, tabulation being often substituted for descriptive sentences, with the result that sometimes the meaning is a little uncertain. Unfortunately, the book contains mistakes in English, Latin, logic and anatomy.

Mikrochemie des Blutes. Von Dr. Friedrich Rappaport, Assistent am Institut für allgemeine und experimentelle Pathologie der Universität Wien. Monographien aus dem Gesamtgebiete der Mikrochemie. Mit einem Vorwort von Prof. Dr. Fritz Silberstein. Paper. Price 15 marks. Pp. 206 with 51 illustrations. Vienna & Leipzig: Emil Halm & Co., 1935.

This concise textbook on microchemical technique as applied to blood is essentially a book of methods. It is written presumably for the laboratory technician. Before the discussion of each method is a brief outline of the underlying principle. The methods are described in a clear and explicit manner, and examples of calculations of the results are given under each description. It is doubtful whether this book will be received in the English speaking countries, where the Folin system of blood analysis is employed. The author has seen fit to replace practically every method that is standard in this country with one of his own choice without any apparent justification. The book is well organized and clearly presented but it is doubtful whether it will be well received here.

Blood Groups and Blood Transfusion By Alexander S Wiener A B M D Cloth. Price \$4 Pp 220 with 41 Illustrations Springfield Ill & Baltimore Charles C Thomas 1935

The special and most prominent feature of this book is the discussion of the recent developments of the forensic and legal applications of the blood groupings. Of the total pages, not more than half have practical value for the practicing physician but in them practically all that is of value is included. The remainder is an important summary of hematology and blood groups of special value to students interested in the anthropologic, ethnologic and genetic phases of blood groupings.

Directory of Catholic Hospitals and Allied Agencies of the United States and Canada 1935 Bulletin No 21 Reprinted from Hospital Progress Official Journal of the Catholic Hospital Association Paper Pp 48 St Louis Catholic Hospital Association of the United States and Canada 1935

This is the most complete source of information that is known in the form of an annual census, concerning all Catholic hospitals

Medicolegal

Compensation of Physicians Liability of County for Emergency Services Rendered Indigents—An indigent patient was brought to the office of the plaintiff, a physician. A diagnosis of ruptured appendix was made and the patient was placed in a hospital. The plaintiff communicated immediately with the proper county commissioners, informing them of the critical condition of the patient and requesting an order to operate. The plaintiff was informed that no action could be taken until the commissioners met. Believing that further delay would prove fatal, the plaintiff operated and restored the patient to health. The county board of commissioners refused to pay the bill and the plaintiff sued and obtained judgment against the county in the trial court. The county appealed to the Supreme Court of Nebraska.

In affirming the judgment of the trial court, the Supreme Court said that in an emergency requiring an operation to save the life of an indigent the physician should, if reasonably possible, attempt to communicate with the proper authorities charged with the care of the poor of the county, but if an order to operate should be arbitrarily refused, or if the authorities should be noncommittal, the necessary services may nevertheless be rendered, and the law imposes an obligation on the county to pay the reasonable value thereof—*Miller v Banner County, (Neb.) 256 N W 639*

Malpractice Burns Following Diathermic Treatment—The plaintiff sued the defendant-physician for damages for a burn on his back, which he attributed to a diathermic treatment by the defendant. According to the plaintiff's testimony, about two minutes after the plates had been applied and the electric current turned on he complained of heat to the defendant's nurse-employee, who was present in the room with him. A few minutes later he complained again and asked that the current be turned off and that the defendant be called, but the nurse did not heed him. When the defendant came into the room a moment later and removed the plates from the plaintiff's back and abdomen, the plaintiff, according to his testimony, "felt an awful pain as though flesh was coming off" and could smell the burning. The defendant-physician and his nurse testified, however, that the plaintiff did not complain of heat and was not burned in the treatment. From a judgment for the plaintiff, the physician appealed to the Supreme Court of Michigan.

Despite frequent warnings from the trial court that his course was hazardous, the plaintiff presented his case in reverse order producing medical witnesses and asking hypothetical questions before the plaintiff testified. He was allowed to do so on his assurance that evidence of the basic facts for his hypothetical questions would be presented later. Several of his hypothetical questions, however, seem to have been based on assumed facts and circumstances not shown by subsequent evi-

dence. The order of proof, said the Supreme Court, on appeal, is largely in the discretion of the trial court, but the practice employed in this case is not to be commended, it prevents opposing counsel from making specific objections to hypothetical questions and hinders the court in its efforts to keep the testimony to the issue. The controlling hypothetical question, to ascertain the duty of the physician under local practice, was grounded on the statement that the patient "repeatedly" complained of being "burned." The plaintiff did not precisely so state. If the case had been presented in an ordinary manner, the question would have been excluded, but the answer given was that the defendant should have shut off the current and investigated by removing the plates. For this and other reasons, judgment was reversed and a new trial ordered—*Sima v Wright (Mich.), 256 N W 349*

Malpractice Sloughing of Tissue Following Subcutaneous Injection of Dextrose Solution—The plaintiff was operated on by Dr Ward for appendicitis. The operation revealed that the appendix had ruptured and that the plaintiff was "in the last throes of peritonitis." In order to save the patient's life, a saline solution containing 10 per cent dextrose was injected in her thighs. The intravenous method of injection could not be used because of the toxic condition of the plaintiff. A sloughing of the tissues resulted. Thereupon the plaintiff sued the hospital, the extern who administered the injections, a nurse who assisted the extern, Dr Ward, the operating physician, and Dr McGavack, the attending physician who administered the anesthetic. A nonsuit was granted as to the nurse. The jury returned a verdict for the hospital and the extern but gave judgment against Drs McGavack and Ward, who thereupon appealed to the district court of appeals, first district division 2, California. There the judgment of the trial court was reversed with directions to enter judgment in favor of the physicians. *Callahan v Hahnemann Hospital et al (Calif.), 26 P (2d) 506*, abstracted in THE JOURNAL, July 14, 1934, page 134.

The case was transferred to the Supreme Court of California and after careful study of the briefs and arguments that court concluded that the district court of appeals had correctly determined all questions of law and fact. The paramount duty of the physicians under the circumstances of this particular case was to endeavor to save the life of the patient and it was not malpractice to save the patient's life, even though this was accomplished by the injection of a solution containing a higher percentage of dextrose than is ordinarily injected subcutaneously, and even though sloughing resulted at the point of injection. There was no suggestion that the physicians did not possess the requisite skill or that they did not exercise their best judgment. The selection of a method of treatment is a matter of judgment. Physicians are not to be confined in their selection of methods of treatment to the use of those methods if any, which have the universal approval of all members of the profession—*Callahan v Hahnemann Hospital et al (Calif.) 35 P (2d) 536*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THIS JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Management of Varicose Veins—Bobo, in examining a varicosed leg, places a tourniquet round the lower part of the thigh just tight enough to obstruct venous return in the superficial system and allows the patient to walk about the room for several minutes in order to observe the final test of efficiency in the one system of deep veins. When there is little discomfort or no pain or cramps and no marked distention of varices, the deep veins are furnishing sufficient venous return and the varicosed ones should be injected. If there is pain and great distention, beyond the usual size of the varicosities, with marked discoloration of the skin, there is an obstruction to circulation through a failure of the venous blood to find a channel for return and injection is contraindicated. If there is marked back pressure of blood, and the tests confirm the fact that it is from the long saphenous, there is some advantage in ligating it high up on the thigh. This eliminates most of the pressure and the actual downward flow of blood through this vein. The author employs only sodium morrhuate, and quinine and urethane. He has the patient sit on the end of the table with the foot dependent and resting on a small stool. The skin is prepared with alcohol. Injection is made directly into the lower part of the vein. The needle being in the lumen of the vein pressure is made just below its point by the thumb of the left hand and just above by the index finger. If the finger is moved upward, the vein is flattened and the capacity of the venous segment to be injected is markedly diminished, so that a smaller amount of solution can be injected and still come in contact with the whole intima, the amount varying from 3 or 4 minims (0.2 or 0.25 cc.) to 1 cc. The needle is withdrawn and the thumb and finger are held in position for two minutes, this being ample time to produce the necessary irritation to the line of the vein. A small compress is placed over the injected site. Two or three injections to each leg are made at a sitting. The patient wears a bandage and reports in one week for further injections. The support should be worn for a month or two after the injections are completed. The author's treatment of varicose ulcers evolves around the Unna paste boot. The boot is applicable to ulcers that are not actively infected but are in a latent stage or in the stage of repair. Case reports are given, showing the value of the treatment.

Injuries to Vertebrae Following Lumbar Puncture—Perse states that many persons complain of pain in the lower part of the back following lumbar puncture. A study of twelve cases showed a thinning of the intervertebral disks and a definite sclerosis of the vertebral bodies, the results of loss of material from the nucleus and of irritation of the bone. Five of these occurred following the withdrawal of fluid for diagnosis, five following the intraspinal administration of anti-meningococcus serum, one following an encephalogram and one following the administration of spinal anesthesia. In performing lumbar punctures on cadavers it was learned that one cannot determine when the point of the needle is actually in the neural canal. In some cases there was a slight decrease in resistance when the canal was reached, but this occurred only when the needle was introduced very delicately. However, in the majority of cases it was impossible to determine the position of the point of the needle. Similarly, if the needle was pushed in too far, one could not tell when it struck the intervertebral disk and passed into it. On the other hand, it was not difficult to ascertain the situation when the point of the needle struck a bony portion of the vertebra. Further experimental puncture on cadavers revealed that there were several possible terminations if the needle was pushed beyond the neural canal: the most common sites being the intervertebral disk, a vertebra, interarticular facets and venous sinusoids in the vertebral body. The purpose of the author's discussion is not to discourage lumbar puncture but rather to call attention to the new complications that may be added to the already long list of accidents resulting from the withdrawal of spinal fluid. In performing a lumbar puncture it is possible, unknowingly, to introduce the needle too far, penetrating the intervertebral disk or the vertebra. The sequels from this may be a narrowing of the intervertebral space, which can be demonstrated by roentgenograms. Various types of inflammatory reactions may be set up in the bony and articular elements of the spine.

Eosinophilia in Scarlet Fever—To determine how helpful the eosinophil count may be in the early diagnosis of scarlet fever, Friedman made this count in 100 cases of scarlet fever. All counts were made at approximately the same time of day, 3 p. m. Blood smears were made by the slide method and stained with Wright's stain. A single examination of the blood revealed an elevated eosinophil count in 46 per cent of the cases in the early stages of the disease. Most of the elevated counts ranged from 5 to 8 per cent. The highest count recorded was 17 per cent. There was an elevated eosinophil count in 60 per

cent of the mild cases but in only 18.2 per cent of the moderate cases and in none of the severe cases. Forty-two of the forty-six patients giving an elevated eosinophil count in the early stages of the disease had a mild form of the disease. In the early stages, 62.1 per cent of the patients exhibiting a slight or a very slight rash had an elevated eosinophil count, while only 31 per cent of those with a moderate rash and 77 per cent of those with a bright or intense rash had an elevated eosinophil count. The relationship between the degree of constitutional symptoms, as typified by the temperature, and the eosinophil count is similar to the relation between the severity of the case and the eosinophil count. The type of case in which an elevated eosinophil count is most likely to be seen in an early stage of the disease is the mild case with only a slight rash and mild constitutional symptoms.

Upper Respiratory and Gastro-Intestinal Infection in Infants—Kahn isolated *Bacillus Morganii* I from the stools of five out of six infants with gastro-enteritis associated with infection of the upper respiratory tract, of fifteen out of twenty-one controls and of fourteen out of thirty-eight infants from a well baby clinic. *Bacillus Morganii* I, *B. paracoli* and *Proteus asiaticus* can be recovered with much greater frequency than previously reported if repeated cultures of the stools are made. *Bacillus Morganii* I, like *B. coli* not normally pathogenic for man, may assume pathogenic characteristics in a small number of cases. The mere recovery of *B. Morganii* I from the diarrheal stool is not proof of its pathogenicity. This is also true for *B. paracoli*, *Proteus asiaticus*, *B. dysenteriae* Schmitz, *B. dispar*, *B. paratyphoid C* and the proteolytic bacteria. Additional evidence must be obtained to prove the pathogenicity of these organisms, namely, agglutination in high dilution with the blood serum of the suspected patient. The close clinical relationship of otitis media and infection of the upper respiratory tract to diarrhea in infants under 2 years of age is probably not due to infection of the intestinal tract with pathogenic organisms in the great majority of cases. The clinical relationship may be the manifestation of allergy or of absorption of toxins from a pathologic process in the upper respiratory tract.

Fusospirochetal Pneumonia—Peirce and Field believe that fusospirochetal pneumonia is a disease entity of definite etiology. They present eleven cases. It is characterized by a prodromal period, more or less prolonged, with dry cough, malaise and pleural pain as dominant symptoms. The gravity of the roentgen evidence of a subsequent bronchopneumonia to confluent lobular pneumonia is out of proportion to the relatively mild constitutional reaction. The sputum commonly has a "mousy" rather than a foul odor, is sometimes bloody and contains many fusiform bacilli and spirochetes, in addition to other organisms commonly associated with them in the mouth. Darkfield examination and gentian violet or silver stains of freshly washed specimens are advisable in the suspected case. There is a considerable tendency to exacerbation, spread of involvement, pleural

effusion or atelectasis. Convalescence is commonly slow. Conservative treatment with complete bed rest has yielded excellent results. Bronchiectasis has been observed early in the course of two cases, followed by partial to complete repair. Arsphenamine and neoarsphenamine have not been of marked therapeutic value.

Injuries to Supraspinatus Tendon Attachment—Henry feels that many cases of undiagnosed disability of the shoulder are caused by evulsion of the supraspinatus tendon from the greater tuberosity of the humerus and that roentgen evidence should be an aid in helping to establish proper diagnosis. Soft tissue roentgen technique with anteroposterior views with the arm in adduction and complete internal rotation reveals the site of insertion of the supraspinatus tendon in silhouette on the humerus. The pathologic observations follow exactly the anatomic descriptions by Codman and others. They are illustrated by six typical cases. Immediately after injury fine spicules of bone near or on the periosteal outlines of the greater tuberosity are seen at the site of the insertion of the supraspinatus tendon. Within a few weeks, irregular decreases and increases in density of the evulsed surface and rounding of the tuberosity are observed. From six months to a year later, irregular calcification and occasionally cysts with loss of the tuberosity prominence and disappearance of the sulcus make their appearance. Old lesions may also show proliferation of bone in old callus together with loss of the tuberosity prominence (in this view), loss of the sulcus and rearrangement of the trabeculae in the whole tuberosity and somewhat in the adjacent parts of the head of the humerus.

Thyroidectomy in Advanced Heart Disease—Pratt traces the development of complete thyroidectomy for heart disease and makes suggestions for the extension of the procedure to the arteriosclerotic, renal and syphilitic groups, with the presentation of case summaries. He discusses a routine preoperative operative and postoperative regimen and presents results in nineteen cases. He cites the dangers of the procedure, which include mortality during operation, tetany, recurrent laryngeal nerve injury, pulmonary complication, infection and hemorrhage with asphyxia. His observations suggest that in the routine thyroidectomy for goiter more of the gland should be removed. The large proportion of recurrence of the tumor following the old lobectomy emphasized how rapidly the remainder of the gland will hypertrophy. Especially when there is cardiac involvement, it is safer to chance the occasional myxedema than the resultant cardiac disturbance from the hyperplasia of a small piece of retained gland. The continuation or recurrence

of cardiac symptoms after thyroidectomy for toxic goiter is due, the author believes, to this removal of insufficient gland and not to a dysfunction of the adrenals or other internal secreting glands. When the cardiac lesion is advanced, the surgeon should remove all of the gland that he can find and even then the danger will be in the retention of too much tissue. Only cases in which other therapeutic measures have failed are considered eligible for the operative procedure. Acute cases are eliminated. The author does not eliminate the syphilitic or arteriosclerotic types. He believes that the possible benefit of complete thyroidectomy in advanced tuberculosis should be considered and in the light of the present investigations it seems plausible. The restless hyperactive state that often affects the tuberculous patient could certainly be arrested and the myxoedematous tendency with slow movements, increase in weight and the desire to rest most of the time should be conducive to pulmonary healing.

Prevention of Postoperative Embolism and Phlebitis
—During the last twelve months, Grumble has employed two measures which in his opinion have had a definite preventive effect on the development of postoperative embolism and phlebitis. 1 The employment of carbon dioxide and oxygen postoperatively, which was originally instituted as a preventive of postoperative pneumonia, he has come to believe serves an equally useful purpose as a measure for preventing the occurrence of phlebitis and pulmonary embolism by the forcing of deep respiration at a period when all vital functions are at a low level. After twenty-four hours carbon dioxide and oxygen are substituted for routine deep breathing exercises. 2 An equally if not more important measure in promoting the flow of venous blood in the lower extremities is the maintenance of the muscle tone and contraction of the muscles of the legs. This is accomplished by the systematic daily use beginning the first day after operation, of a device consisting of two bicycle pedals mounted on a broad base, which can be placed conveniently in the bed for exercising the lower limbs. There has not been a single case of either condition when the two procedures have been employed, whereas in a similar number in which these measures were not employed there has been one fatal case of pulmonary embolism and three cases of phlebitis of the lower extremities. Another advantage of the exerciser is the maintenance of body strength.

Acute Cerebellar Abscess—Shambaugh reports the case of a child who was admitted to the hospital during the eruptive stage of scarlet fever. During hospitalization acute suppurative otitis media developed, complicated by thrombosis of the lateral sinus and followed by the development of a cerebellar abscess. By reviewing the clinical course in this case one can reconstruct

and visualize the pathologic changes that occurred at each stage from the initial cerebral invasion to encapsulation, drainage and recovery. The stage of invasion of the abscess of the brain was characterized by predominating systemic symptoms (fever) from the advancing thrombophlebitis, the symptoms of local cerebral involvement (vomiting) being minimal. The second stage that of early necrosis and encephalitis, was characterized by signs of rapidly increasing intracranial pressure with localizing neurologic signs beginning to appear. The third stage, that of encapsulation was characterized by continued signs of increased intracranial pressure, but with the localizing neurologic signs predominating. The stage of recovery was marked by rapid disappearance of the signs of increased intracranial pressure followed by a more gradual recovery from the neurologic changes. Encapsulation was definitely developed three and one half weeks after the initial cerebral invasion. Repeated aspirations were not sufficient. Constant drainage was necessary. The encephalitis surrounding the abscess was more threatening to life than the abscess itself. Had a larger drain been inserted or any attempt been made to suck out, inspect or pack the abscess cavity, the added encephalitis would probably have been fatal. In cases of acute abscess of the brain, drainage must be established with a minimum of trauma to the tissue. A rubber catheter makes a satisfactory drain, but it must actually penetrate the capsule. A preliminary decompression will relieve the acute symptoms in the early stages and allow delay in exploring until encapsulation and walling off have occurred. By limiting the dural opening to a simple half inch (1.27 cm) incision massive herniation is prevented. The neurologic signs of abscess of the brain were due more to the associated encephalitis than to the actual necrosis of brain tissue, as evidenced by the complete restoration of cerebellar function.

Electrosurgical Obliteration of Gallbladder—Thorek believes that failures and fatalities in classic cholecystectomy are frequently due to bile leakage, as a result of an inability to obliterate and cover the gallbladder bed, which contains bile capillaries and often larger bile ducts in from 15 to 25 per cent of cases. Electrosurgical obliteration of the gallbladder, when carefully carried out, may be used in simple and complicated cases of gallbladder disease without resorting to drainage. It reduces morbidity and mortality to a minimum and shortens hospitalization. The much dreaded age factor loses its terror. Shock is absent. The term cholecystelectrocoagulation is descriptive of the procedure. A prerequisite to the achievement of satisfactory results is a patent common duct. An occluded cystic duct from any cause is an indication for cholecystelectrocoagulation. Cholecystelectrocoagulation is free from the drawbacks of carbonization and effectively accomplishes destruction of the entire thickness of the gallbladder and gallbladder bed. The surgeon has under control the degree of penetration he wishes to accomplish. The falciform ligament is used as a pedicle or free graft in covering sutured or raw surfaces to great advantage, thus reinforcing and protecting the areas concerned against seepage and safeguarding the processes of repair. Electrocoagulated areas in intra-abdominal organs tend to heal by encapsulation. They do not interfere with wound healing but heal promptly when the wound is closed securely. Therefore, drainage is not only undesirable but is distinctly deleterious. Drainage prolongs the healing process and predisposes to infection. Cholecystelectrocoagulation eliminates the necessity of drainage and its unpleasant sequelae. This method when properly carried out substitutes for a leaking, unprotected, raw surface in the gallbladder bed a sterile, hyaline, dry protective layer. A series of 118 consecutive, unselected cases were thus treated without a fatality.

Resection of Stomach for Carcinoma—Holman believes that whenever feasible subtotal gastrectomy with complete resection of the lesser curvature is the method most likely to ensure complete removal of the original growth and the involved lymphatic channels and nodes in gastric carcinoma. Formation of a small tubelike stomach from the remaining greater curvature permits reestablishment of gastro intestinal continuity by end-to-side anastomosis with the jejunum. A retrocolic anastomosis is preferable, but no traction at the site of union by the mesocolon is permissible and, when imminent, should be avoided by an antecolic gastro-enterostomy, supplemented by a jejuno-jejunostomy. Avoidance of bleeding at the operation and complete hemostasis by direct ligation of all individual bleeding vessels prevent embarrassing postoperative complications. To improve the results in the treatment of gastric cancer every "corporic" ulcer located off the lesser curvature should be treated, from the moment its presence is demonstrated, as probably neoplastic in origin and therefore subject to subtotal resection, and every gastric ulcer on the lesser curvature should be resected if two months of well controlled medical care does not both relieve symptoms and cause a diminution in the size of the ulcer with ultimate disappearance of the ulcer. Every ulceration on the gastric side of the pylorus, accompanied by symptoms that persist in the face of medical care, should be considered probably neoplastic in origin and therefore subject to resection. It cannot be emphasized too strongly that the absence of anemia, loss of weight and palpable tumor and the presence of a normal gastric acidity are not incompatible with gastric cancer.

Cholesterol Content of Plasma in Arthritis—Hartung and Bruger compared the plasma cholesterol in arthritic patients with cholesterol studies in thirty-three normal subjects. In the rheumatoid group (thirty-three cases) the average age was 39 years, 63 per cent of the patients were women. The mean total cholesterol was 175.2 ± 39.5 mg per hundred cubic centimeters of plasma. When these figures were compared with the control group the results indicated that 49 per cent of the rheumatoid cases gave normal values, 39 per cent showed hypcholesterolemia and 12 per cent showed hypercholesterolemia. The esterified cholesterol showed a normal relation to the total cholesterol, varying from 46.6 to 76.8 per cent with a mean of 60.9 per cent. No absolute correlation was observed between the total plasma cholesterol and the sedimentation rate. In the osteo-arthritic group of fifty-nine patients the average age was 51 years, 90 per cent were women. The mean total cholesterol was 235.4 ± 45 mg per hundred cubic centimeters of plasma. Hypercholesterolemia was observed in 62 per cent, 35 per cent gave normal values and only 3 per cent showed hypcholesterolemia. The cholesterol esters in this group also showed a normal relation to the total cholesterol, varying from 42.9 to 75.3 per cent with a mean of 59.4 per cent. Here again no definite correlation was observed between the sedimentation rate and the total blood cholesterol. The plasma cholesterol tends to be low in rheumatoid arthritis and elevated in osteo-arthritis. These observations lend added proof to the theory that rheumatoid arthritis is an infectious disease and osteo-arthritis a degenerative one.

Blood Wassermann Test in Neurosyphilis—Menninger and Bromberg present the status of the blood Wassermann test in 500 cases of clinical neurosyphilis with positive spinal fluids. In the entire group of all clinical types of neurosyphilis, 155 (31 per cent) showed negative blood Wassermann tests early in their study. Twenty-one patients showed a one plus blood Wassermann test, 62 patients showed two plus, 42 patients showed three plus and 220 patients showed a four plus blood Wassermann test. In 297 cases of asymptomatic neurosyphilis, 101 patients showed a negative blood Wassermann test. In 133 cases of tabes dorsalis, 37 patients showed a negative blood Wassermann test. In 38 cases of dementia paralytica, 8 patients showed a negative blood Wassermann test. In 19

cases of dementia paralytica with tabes, 5 patients showed a negative blood Wassermann test. In 13 cases of meningovascular neurosyphilis, 4 patients showed a negative blood Wassermann test. The Kahn test was positive in 38 cases showing a negative blood Wassermann reaction. If this number of cases is deducted from the 155 showing a negative blood Wassermann reaction, there remain 117 patients with both the Kahn and Wassermann tests of the blood negative. The investigation shows that no case of syphilis after the early stage can be regarded as completely studied, accurately diagnosed or correctly treated without knowledge of the cerebrospinal fluid observations.

Eosinophilia in Syphilis—Spangler made a comparative study of the differential leukocyte counts in 100 men having positive and 100 men with negative blood Wassermann reactions. The study of differential blood counts in patients with positive Wassermann reactions tends to indicate that a moderate eosinophilia occurs and is discoverable, if repeated counts are made at various stages of the patient's response to the specific toxin of the parasite of syphilis, in at least 40 per cent or more of the cases. It seems reasonable to assume therefore, that the eosinophilia occurring in syphilis may be regarded as distinct evidence of the blood's reaction to the sensitizing (toxic) substance of *Spirocheta pallida* and that it is indicative of the patient's development of an allergic cellular mechanism of defense. With the hypothesis that eosinophilia is a criterion of allergy and with the finding of an eosinophilia in individuals with positive Wassermann reactions in various stages of syphilitic infection, the possible immunologic relation of allergy and syphilis would appear to justify careful study. With the admittedly high incidence of unrecognized syphilitic infection and the unknown basic factor of many allergic metabolic disturbances, any clue leading to a definite diagnosis and of possible aid in solving the mechanism involved in the systemic eosinophilogenic response would seem worthy of attention and investigation from an immunologic standpoint. It seems justifiable that a moderate degree of eosinophilia, especially when associated with a lymphocytosis, occurring even periodically in an apparently nonallergic person whose intestinal tract is free from ova and parasites, warrants the taking of Wassermann tests and the making of a persistent search for clinical evidence of syphilis.

Encephalomyelitis Disseminata Following Ascending Neuritis—Thompson reports a case in which persistent pain in the left deltoid region began two weeks after the apparent recovery of a purulent infection of the left index finger and hand and changed gradually to a paresthesia of numbness involving the entire left limb. This was indicative of an extension of the infection into the peripheral neural system. Coexisting numbness of the upper portion of the left side of the trunk was a manifestation of extension of the morbid condition farther than the periphery and was the first presumptive evidence of involvement of the spinal cord, i. e., the left posterior column in its outer portion, the fasciculus cuneatus. The further progress of the paresthesia coincided with the anatomic distribution of the fibers within the posterior column. The clinical course implied a progressive segmental invasion of the posterior column of the left side ascending from the posterior roots of the spinal nerves for the neck and upper limb. The paresthesia of numbness, therefore, was of particular localizing value. It marks a lesion beginning in the peripheral portion of the left posterior column and gradually extending transversely inward to involve within approximately fifty-nine days the fibers from the thoracic and caudal end of the left side of

the trunk and the left lower limb. At this time other symptoms of involvements of the left posterior column were noticed: incoordination of the left hand and uncertainty and weakness of the movements of the left lower limb. About six weeks later numbness was noted in the right foot, gradually extending into the leg and then into the thigh, where its progress stopped. That the myelitic process included to a slight degree the left pyramidal pathway is evidenced by the presence of weakness in the left limbs with increased reflex tendon activity and patella and ankle clonus. The sensory examinations revealed intactness of the functions of the spinothalamic pathways. The distribution of the atrophy and the absence of any indication of fibrillary twitching seem to imply that the left brachial and cervical plexuses were the determining cause. The first indication of intracranial neural involvement was the appearance of diplopia about six weeks following the onset of pain in the deltoid region or eight weeks after the subsidence of the infection of the finger. It is still present and is due to weakness of the left external rectus muscle. Clinical and experimental evidence indicates that toxins or infections may pass through large areas of nervous tissue without causing pathologic changes. The process ascending in the perineural lymph spaces has two pathways for further propagation: the axis cylinders and the cerebrospinal fluid, and each avenue of possible distribution has many followers.

Relation of Frontal Lobes to Visceral Function—Watts describes experiments that suggest an explanation of the long recognized visceral symptoms and signs associated with focal seizures in man, especially those which occur in the absence of increased intracranial pressure. He found that the removal of cortical influence by extirpation of both premotor areas results in increased peristalsis and in some instances in intussusception. Faradic stimulation of the premotor area and certain adjoining parts of the cerebral cortex initiates vigorous movements of all parts of the intestine. Evidence is given indicating that cortical representation for the gastro-intestinal tract contains both excitatory and inhibitory components. An epigastric aura and other visceral sensations associated with focal convulsive seizures or occurring independently usually are not so-called referred sensations but result from vigorous and, perhaps, abnormal gastro-intestinal movements. Morbid hunger, associated with brain tumors, cerebral vascular disease and accidental injury to the brain, is probably due to irritation or destruction of the intestinal representation in the cortex or of tracts arising there. Evidence is presented indicating that incontinence of urine and other forms of bladder dysfunction in patients with brain tumor are probably the result of a disturbance of bladder representation in certain parts of the brain or of tracts descending from them.

Traumatic and Hemorrhagic Shock.—Coonse and his co-workers differentiate traumatic from hemorrhagic shock. Traumatic shock is characterized by increasing acidosis and concentration of the blood (a relative increase of cells over serum as measured by hematocrit determination) in acute hemorrhagic shock, acidosis does not develop (the blood may show dilution with relative increase of serum over cells) and the effects are entirely due to loss of circulating blood volume. In slow hemorrhage, the changes more nearly resemble those of traumatic shock. Such cases usually show depression of the higher centers, increasing tissue anoxemia and acidosis. Blood volume loss in both instances plays a significant part. The effectiveness of the peripheral circulation is steadily diminished as the blood volume decreases. Interference with the function of the vital centers rapidly ensues. Depression of the respiratory center decreases the chest and abdominal excursions, resulting in a diminution of the normal negative intrapleural pressure. The return of blood to the heart is diminished as blood collects in the abdominal viscera and large venous radicles and smaller peripheral vessels. The diminished oxygen exchange in the periphery resulting from the altered mechanics of the circulation tends to create a vicious cycle of increasing anoxic acidosis, the vital centers becoming still further depressed. The depressant and toxic effects of laked blood and traumatized muscle on the higher centers have been demonstrated in the experimental animal. Hemolysis has been shown to be consistently present in traumatic shock. Acute hemorrhagic shock is best treated by replacement of the lost volume with whole blood. Less severe cases respond satisfactorily to intravenous saline solution, dextrose or acacia and require no other treatment. Traumatic or slow hemorrhagic shock is best treated by intravenous alkaline solution or its combination with whole blood. Even severe cases of traumatic shock respond well to intravenous alkaline solution, if given in sufficient quantities over a suitable period of time. Such alkaline solutions not only prevent acidosis but serve as direct cell stimulants to the respiratory and other vital centers. Alkali increases the rate of dissociation of oxyhemoglobin and improves the peripheral blood flow. In certain cases, supplementary inhalations of carbon dioxide and oxygen may be indicated for both mechanical and chemical effects.

Noncalculus Obstructions at Ureteropelvic Junction—Bidgood and Roberts state that, because a kidney shows no evidence of function as tested by dye secretion, it cannot be said that it is irreparably damaged. Simultaneous bilateral urine urea determinations are of use in doubtful cases. An accurate test of kidney reserve as an index of its recuperative

ability is desirable but is not available at present. Pelvic injections at operation are of assistance in demonstrating whether or not all factors tending to obstruct have been removed, and, unless every such impediment is removed, failure will often occur. The Rammstedt type of operation for fibrous narrowing of the ureteral lumen presents several advantages over the Heineke-Mikulicz principle. It does not entail the opening of the urinary tract, there is no limit to the length that the incision may be made, and there is no danger of puckering the opposite wall of the ureter. Pelvic infection will often subside spontaneously if free drainage is obtained. Clinical and functional improvement is often more satisfactory than the roentgenologic, in that the dilatation of the pelvis often persists. It is possible that, if a pelvis is dilated sufficiently over a period of time, it loses its muscular tone and will not contract to the usual normal size, even though it is draining well and is dynamically satisfactory. Before any operative procedure is attempted, coned down interval pyelographs of the ureteropelvic junction to determine the emptying time of the pelvis are of value, particularly when used in comparison with a similar study made after such a plastic or other operative procedure. Excretion urography may be an aid in determining the emptying ability of a pelvis, but only when a solitary kidney is present or one acting as such. The postoperative degree of dilatation of the kidney pelvis or calices as noted in a pyelogram is not an accurate criterion of the functioning capacity of the kidney.

Roentgen Diagnosis of Chronic Arthritis—Douth states that osteoporosis is one of the prominent roentgen signs of atrophic arthritis, in hypertrophic arthritis eburnation or increased density is usually present. The density of the bones is even greater than that usually seen in normal bones of this

age period, as some grade of osteoporosis is usually seen after middle age. Both show evidence of cartilage destruction with narrowing of the joint space, but this process is more pronounced and occurs earlier in atrophic arthritis. Bone proliferation in atrophic arthritis is usually followed by ankylosis of the joint, while in the hypertrophic form marginalipping is one of the characteristic early roentgen signs and may not indicate the presence of any symptoms at that time. Ankylosis is an infrequent occurrence in hypertrophic arthritis, although extensive bone production may be present about the joints. Mixed types of arthritis are seen frequently. In some cases it is difficult to distinguish between the two types from pathologic specimens, either by gross or by microscopic examination. Some of the pathologic and roentgenologic changes seen at certain stages of chronic arthritis are quite similar to those seen in other types of arthritis. Tuberculous and atrophic arthritis have some points of similarity. Osteoporosis is a definite characteristic of each at certain stages. Cartilage destruction is common to the two, focal areas of bone erosion may occur in each, and pannus formation may be present over the cartilage. Osteoporosis in tuberculous arthritis is likely to be quite intense so that the articular surfaces are seen with difficulty and show a blurred appearance, greater than usually seen in atrophic arthritis, and suggests that there is an osteolytic agent present. Hemophilic arthritis may present roentgen signs that are similar to those of chronic arthritis. In mild cases there is effusion into the joint space, thickening of the joint capsule and lipping similar to that seen in hypertrophic arthritis. In a more advanced group, cartilaginous destruction is found. This may be local or may involve the entire cartilaginous surface of the joint. There is also bone destruction of punched out areas in the epiphysis, with an intact articular surface due to hemorrhage into the epiphysis, and generalized destruction of the articular surfaces. In some cases the blood clot in the synovial cavity becomes organized and shows calcification, when this occurs, it is pathognomonic of hemophilic arthritis. The roentgen changes in gout may simulate those of chronic arthritis and are well defined rounded areas of destruction in the ends of the bones at the margins of the articular surfaces. There also may be destruction of the articular cartilage and erosion of the articular surfaces of the bones. There is usually not much osteoporosis present. In some of the milder cases there is lipping round the articular surfaces similar to that seen in hypertrophic arthritis. When the larger joints are involved the changes often suggest hypertrophic arthritis, but in these cases roentgenograms of the hands and feet may show the characteristic punched out areas of bone destruction and afford a clue to the etiology of the disease.

Congenital Lung Cysts in Children—Schenck and Stein point out that, although the etiology of congenital cysts of the lungs is still obscure, the opinion prevails that it is a congenital malformation or developmental error, which results in a dilatation of the terminal bronchiole filled with a tenacious glairy fluid. If the cyst communicates with an adjacent bronchiole, this fluid is replaced by air and may remain stationary in size, provided the communication is patent during both phases of respiration. If the air is allowed to enter the cystic cavity and the communicating channel collapses or is closed off during the expiratory phase, the cyst enlarges or balloons, thereby producing severe attacks of dyspnea and cyanosis which often terminate in death. A similar mechanism obtains in the case of multiple or honeycombed cysts. The diagnosis is made chiefly from a complete roentgenologic survey, and the condition must be differentiated from general or localized pneumothorax, lung abscess, encapsulated fluid, pneumonia, solid tumors and acquired cystic disease, such as bronchiectasia, echinococcal cyst and hydatid cyst. The prognosis is grave, especially in infants, and only four are known to have made a complete spontaneous recovery. No specific treatment can be offered, although the opinion is expressed that surgical removal will some day be a feasible procedure. The authors cite a case in an infant in which the cyst ruptured into a neighboring bronchus, evacuating its fluid contents, which were replaced by air. Subsequently, the walls of the cyst collapsed and were absorbed, and the infant made a complete recovery.

Gritti-Stokes Amputation for Gangrene of Leg—Snyder performed the Gritti-Stokes type of amputation in seven cases of gangrene of the leg. Some reason attends this type of procedure in that the larger muscle bodies of the thigh are left undisturbed with no incision across their structures and no disturbance of their circulation. The nutrient artery to the femur enters at a higher level from the profunda femoris and, as division of the femur just above the condyles does not open the marrow cavity of the bone, reasonable assurance of the integrity of the femur may be felt. Sloughing of the stumps of the hamstring muscles is of minor importance, the main question is the viability of the flaps and the patella itself. Apparently the rather free anastomosis about the patella is sufficient to maintain its nutrition and in no case has enough necrosis of the flaps ensued to give concern. In most of these operations the tourniquet has not been applied because of fear of producing damage to the circulation in the thigh. It has not been necessary to secure the patella to the femur with screws or nails, as the tension of the quadriceps acting against the patella seems to hold the patella firmly against the femur. Reinforcing sutures are employed. If union of the patella to the femur fails to occur, the stump will not be a success from the mechanical standpoint, but this has not happened in the author's series. He does not present these cases with the thought that this type of operation will always be a success, but the operation is much less severe on the patient than a mid thigh amputation and produces little if any shock when done under a spinal anesthesia. If successful, it gives the patient a far more satisfactory stump.

Neurologic Mechanism of Parathyroid Tetany—West observed (on dogs) that the essential feature of tetany appears to be the action of a circulatory factor peripherally on some site in the muscle to cause repeated contractions of individual muscle fibers and electrical hyperexcitability. Both this fibrillary tetany and the electrical hyperexcitability are influenced by the nerve supply from the central nervous system. Given the integrity of the spinal reflex arc the muscular contractions are synthesized into the characteristic forms of "tonic" and "clonic" tetany. In the presence of only the motor supply from the spinal cord the contractions remain fibrillary in type, but electrical hyperexcitability persists. Complete denervation leads to a continuation of fibrillary tetany and an increased electrical excitability with the onset of tetany. This probably corresponds to a phase of early degeneration at some point of action within the muscle, which maintains its irritability to the circulatory factor of tetany and increases the normal effect of the latter on direct electrical excitability. Subsequent degenerative changes lead successively to the loss of the fibrillary response to the circulatory factor and the institution of a peculiar electrical excitability of degeneration which is independent of tetany. If this interpretation is correct, parathyroid tetany arises essentially from the action of a changed circulation on the muscles. The point of action depends on an intact motor nerve supply for its function and undergoes successive changes of threshold on denervation. An intact spinal reflex is required to convert essential or fibrillary tetany into its elaborate clonic and tonic forms. Impulses from nervous centers higher than the spinal cord are not requisite to these forms of canine tetany.

Familial Degeneration of Cerebellum in Association with Epilepsy—Thorpe describes a familial form of primary parenchymatous atrophy of the cerebellar cortex, in which two brothers, at the ages of 41 and 37 respectively, developed a progressive ataxia of the legs and arms and a slow drawing speech. The anatomic basis of the symptoms was ascertained in one of them after a duration of five years and was found to be a pure cortical type of cerebellar atrophy. The cerebellum was reduced in size by approximately one fourth and showed a generalized symmetrical atrophy with marked emphasis on the upper and anterior surface, especially the superior vermis and quadilateral lobes. Histologically the essential lesion was a diffuse destruction of the cells of Purkinje. This particular type of atrophy has heretofore been described only in non-familial cases unless one includes the Holmes family of four cases, of which the only one in which histologic examination was made showed an olivocerebellar atrophy. Familial degeneration of the cerebellum occurs more often in males, and the onset is between the ages of 32 and 41, whereas nonfamilial forms tend to occur at a much later age. Both forms are assumed to be due to an endogenous degenerative process or atrophy, but in the sporadic cases there may be an additional exogenous infective or toxic factor. The frequent combination of cerebellar atrophy and lesions of the spinal cord is mentioned and in the case described a developmental defect of the cord was found which suggests a latent association with Friedreich's disease. The two patients described were subject to epileptic seizures, which had been present for thirty-eight and eighteen years

before the onset of cerebellar ataxia. The cerebellar lesion, however, was not the focal ischemic type which Spielmeyer finds in most epileptic brains but a gross generalized atrophy typical of the primary degenerations. The association of cerebellar atrophy and epilepsy in the two cases is regarded as accidental and merely represents the not uncommon occurrence of a predisposition to two independent nervous disorders in one individual.

Amputations of Frontal Lobe in Man—Penfield and Evans describe three cases of tumor in which an infiltrating neoplasm has made it advisable to resect a large block of the frontal lobe. The patients suffered from chronic epilepsy due to a focal lesion of such a type and situation that lobe amputation offered the only hope of relief from the seizures. It was found that large amputations of the frontal lobe, if the precentral gyrus is left intact, produce surprisingly little disturbance of function that can be detected by ordinary methods of examination. There is no disturbance of the control of micturition, no forced grasping, no alteration of tone of the extremities or in the activity of deep or superficial reflexes. In the second case the operative removal affected only the middle third of the left frontal lobe, as the anterior third had already been destroyed by the traumatic injury, if one may arbitrarily so divide the lobe. This removal of the middle third in a right-handed man produced a partial loss of his capacity for mental arithmetic. The patient also had an unexplained absence of dizziness and postpointing after rotation and caloric tests, even though vestibular function was otherwise normal. Detailed studies of sensation showed only changes within the limits of normal spontaneous variation. There was decreased appreciation of figures written on the palm of the contralateral hand, which may perhaps be related to the difficulty that the patient noted in the visualization of figures in "mental arithmetic." The removal of approximately the anterior half or two fifths of the right frontal lobe in the third case was not associated with any detected alteration, neurologic or psychologic. The two larger removals, the first two cases present certain important defects in common and the authors consider these removals to have begun at the time of the origin of the initial lesion and merely to have become complete at the time of operation. Neurologically each was normal. By the ordinary psychometric tests each would have to be judged normal although neither would rank very high. Each patient was lacking in initiative. Each was good natured and cooperative. Insight and capacity for introspection were preserved. Capacity to follow instruction was unimpaired, but initiative and capacity for planned action were clearly defective. This was especially true of the first patient, a woman of 43 in whom the right frontal lobe was extirpated. She had become incapable of discerning for herself possible courses of action so that she might choose. If others presented to her the possibilities she made up her mind quite easily, and when a task lay before her there was no reluctance or hesitation in undertaking it. So far as final conclusions from the first two cases are justifiable it may be stated that maximal amputation of the right or left frontal lobe has for its most important detectable sequel impairment of those mental processes which are pre-requisite to planned initiative.

Excretion Urography—On the basis of 385 consecutive cases Barclay and Baird show that intravenous urography is a reliable useful and safe method of investigation not only in the elucidation of essentially urologic conditions but also in

absolving the urinary tract in many cases presenting suggestive urologic symptoms. Contrasting intravenous urography with retrograde pyelography as a means of outlining the urinary tract, they state that the instrumental method gives an anatomic picture of the pelvis and calices by artificially distending them to an unknown degree, while the excretion urogram definitely outlines the shape and size of these cavities with physiologic accuracy. It follows, therefore, that the functional activity and the dynamics of the tract are well visualized, in addition to the anatomy as seen by the retrograde procedure. At least three roentgenograms should be taken at intervals of three, ten and thirty minutes after the injection of the dye and should be compared in order to justify accurate interpretation. Early tuberculosis in the kidney frequently gives characteristic appearances, e. g., "fringing" or bulbous deformation of the calix, together with a tortuous elongation of the stem. Undue retention of the dye in the roentgenogram taken thirty minutes after the injection or later strongly suggests infection or possibly an oxaluria or phosphaturia. Some idea of the functional recovery of the kidney can be obtained by urography at intervals of months after operation, e. g., removal of a ureteral calculus.

Primary Carcinoma of Bronchus—Matheson reports a case of primary carcinoma of the bronchus in which roentgen examination revealed an enormous enlargement of the pericardium. Paracentesis pericardii, with the withdrawal of hemorrhagic fluid, gave temporary relief. At necropsy the chest was almost completely occupied by a rounded and greatly distended pericardial sac, which pressed the lungs into the upper and outer parts of the thoracic cavity. The heart appeared largely obscured by carcinomatous deposits extending over most of the anterior surface with the exception of a somewhat triangular area of the left ventricle. The myocardium was invaded from without by a growth that involved the outer half of the wall of the right auricle and the outer third of the right ventricular wall. The left auricle and left ventricle showed epicardial deposits with no appreciable extension into the cardiac muscle. Great enlargement of the tracheobronchial lymph nodes was observed and chains of diseased glands extended in front of the vertebral column to become continuous with those glands which had been detected clinically on the left side of the neck. Just distal to the subdivision of the right bronchus was a tumor about 2 inches in diameter, extending chiefly into the adjacent tissue of the lung and adherent to the pericardium at the site where the interior of the pericardial cavity was most extensively diseased. The general characters of this growth were those of a bronchogenic carcinoma. Secondary metastases or tuberculous lesions in the parenchyma or visceral pleura were not observed. A solitary nodule the size of a walnut was found in the left deltoid. The bronchial tumor proved to be a squamous cell carcinoma. The nodule in the deltoid appeared to be a true metastasis.

Action of Drugs in Schizophrenia—Beccle treated thirteen cases of schizophrenia with a combination of gonadal hormones and yohimbine. Of the nine male patients so treated seven were discharged as recovered or greatly improved, one improved to the extent that he is now a useful hospital citizen and one showed no response to the treatment. Of four female cases investigated, recovery occurred in three and one patient was definitely made worse. Gonadal extracts appear to be valuable therapeutic agents in the schizophrenic group of psy-

choses with particular emphasis on the female follicular hormone. It is possible that, in spite of the absence of overt indications of sex gland hypoplasia, such a condition may be present and hence may be an important factor in the preparation of the soil for a schizophrenic psychosis. The higher relative recovery rate in the female cases may be purely coincidental or, more probably, may be due to the fact that in estrogenic material there is a substance of known potency and chemical composition, whereas testicular extracts are variable in their activities. Yohimbine acts as a general central nervous tonic, has a specific influence on the genital apparatus and appears to enhance synergically the action of the gonad hormones. No untoward symptoms were observed after the administration of these preparations, either orally or by subcutaneous or intramuscular injection. The blood phosphorus level appears to be distinctly higher in cases of schizophrenia than in the normal person (improvement in the mental condition being followed by a fall in this level (the inorganic fraction being used as an index). This index appears to be of value in controlling the treatment.

Asphyxia Neonatorum—Blakley and Gibberd use a modification of Howarth's Chevalier Jackson's pharyngoscope in the treatment of asphyxia neonatorum by tracheal intubation. The upper respiratory passages having been cleared of mucus, the baby is held with its head overhanging the table on which it lies. The pharyngoscope is introduced over the tongue, to the base of the tongue. The cords are usually relaxed and offer no resistance to the passage of Magill's silk web endotracheal catheter which should be slightly moistened with olive oil. The rest of the apparatus consists of a device for delivering a carbon dioxide-oxygen mixture at a known and easily variable pressure. The whole object of the insufflation is to ensure the primary unfolding of the atelectatic lung, and this requires a pressure in the bronchi equivalent to at least 15 cm. of water. As soon as the primary distention of the alveoli has been accomplished oxygenation of the blood rapidly occurs, so that the medullary center recovers its sensitivity and the flaccid laryngeal muscles recover their tone. Thus it is seldom necessary to leave the catheter in the trachea more than a few minutes, but, if cyanosis recurs subsequently, the operation should be repeated. During insufflation the infant should lie flat on its back at an angle of 15 degrees with the horizontal, head downward. The authors present two results. They have considered the possible dangers of a sudden obstruction to the outflow between the catheter and the larynx, but with the pressures recommended they do not believe that serious damage could occur. They believe that the margin of safety of pressure for forced ventilation by intratracheal insufflation under positive pressure is much greater than the margin of safety when negative pressures are used to expand the whole of the chest wall, as in a Drinker apparatus. The authors do not recommend this method of resuscitation in all cases of asphyxia neonatorum, but, when respiratory movements are not established quickly, or when, because of some mechanical obstruction in the larynx, trachea or bronchi, air is not drawn into the lungs, they believe that the method should be adopted. Other suitable cases are those in which a well developed infant has marked atelectasis and remains blue or has repeated attacks of cyanosis that do not become less frequent with the inhalation of a carbon dioxide and oxygen mixture given by means of a mask or nasal catheter. The proper mixture of gas to introduce into the lungs consists of 5 to 10 per cent carbon dioxide and 90 to 95 per cent oxygen. Pure carbon dioxide must be avoided as lethal if introduced unmixed into the lungs. The real need is for oxygen, the carbon dioxide merely ensures that this gas is not washed out of the blood to so low a level as no longer to be a stimulus to the respiratory center.

 Crushing of One Tuberosity of Tibia L Secheyave—p 561

Hydatid Cysts of Spleen.—Sabadin reports two cases of hydatid cyst of the spleen and discusses the condition in detail. From the anatomic point of view there are two varieties: the abdominal and the thoracic. The characteristic clinical features are the insidious onset, the prolonged evolution of the cysts, the existence of a cystic tumor, a symptomatology sometimes abdominal, sometimes thoracic, and the frequency of complications. From the therapeutic point of view he discusses the advantages of marsupialization either abdominal or trans-thoracic. This fits with established surgical principles, since it is simple and rapid, aims directly at the evacuation of the cyst and avoids serious postoperative risks.

Vitamin A Treatment of Ulcerative Colitis.—Rachet and Bussion used carotene in a solution of deoxygenated olive oil for local application in cases of ulcerative rectocolitis. This method, they believe, is particularly adapted to the localization of the vitamin A factor. Four patients were treated in this manner. Favorable results were definite and could be divided into improvement of the general, the functional and the local anatomic condition. They conclude that this treatment is a definite forward step.

Schweizerische medizinische Wochenschrift, Basel

65: 353 372 (April 20) 1935

 *Nitrites in Urine and Their Importance for Diagnosis of Urinary Infections with Bacillus Coli E Jaeggy and W Lanz—p 363

Granulocytopenia.—Stein thinks that granulocytopenia is not so much a disease entity as a pathologic reaction to certain irritants. He differentiates three groups of such irritants. Those belonging to the first group, benzene, radium rays and roentgen rays, regularly impair the leukopoietic system. To the second group of irritants belong the toxins of typhoid, measles, influenza and sepsis. These toxins attack the leukopoietic system peripherally as well as centrally. The third group of irritants are certain chemical preparations, such as amidopyrine, which, however, prove harmful only in persons who have a hypersensitivity. The author thinks that amidopyrine and its derivatives are the cause of many cases of agranulocytosis that formerly were considered as cryptogenic or idiopathic. He emphasizes that, if the physician prescribes such preparations, he should be aware of the fact that there are patients who are hypersensitive to these substances. Thus it is necessary to exercise the same precaution in prescribing amidopyrine and the related preparations as in prescribing arsenamine and narcotics. The author regards the administration of pentnucleotide and repeated blood transfusions as the best therapeutic measures during the beginning stage. Later, roentgenotherapy may be applied to the long bones and liver therapy may be tried. All medicaments, with the exception of those that stimulate the leukopoietic system, should be discontinued during the acute stage, for it cannot be foretold how a person's blood system will react to a certain medicament.

Nitrites in Urine.—Jaeggy and Lanz demonstrate that the presence of nitrites in the urine is a definite proof of a urinary

infection, particularly an infection with *Bacillus coli*. They describe a simple chemical reaction that will aid the practitioner in the diagnosis. As reagent they use a powder in the preparation of which 6.2 Gm of α -naphthylamine is mixed with 1 Gm of sulphanilic acid and this mixture is combined with 25 Gm of pulverized citric acid. The moist substance thus obtained is dried in the air or in the desiccator. After drying, it is once more pulverized. This powder, white or light pink, is five times more sensitive than the reagent suggested by Griess and it has the added advantage that it is stable. It reveals the presence of nitrites at a concentration of 1 5,000,000.

 Mediastinal Abscess Rare Case G Fontana—p 818
 Distinctive Characteristics of Vitamin C E Pittarelli and M Pittarelli—p 826

Medical Treatment of Duodenal Ulcer.—Sabatini places the patient on a milk diet for from three to five days. He prescribes six portions of milk (2 liters) daily, one portion every three hours from 8 a. m. to 11 p. m. To the first, third and fifth portion is added a level teaspoonful of barium sulphate. The patient does not take any other liquid or solid food during the treatment, abstains from all medicaments and does not remain in bed. After the treatment the return to a normal diet must be gradual, increasing in food values and in amounts every day. During this period of alimentary repair the author occasionally administers an alkaline mixture composed of bis-muth subcarbonate 1, magnesium carbonate 0.3, pepsin hydrochloride acid 0.3 and dry extract of belladonna 0.1 in a capsule. Patients show more tolerance for barium sulphate than for bismuth compounds. The majority of patients were rapidly relieved of pain and of the clinical symptoms of ulcer. The author obtained good results in acute forms of duodenal ulcer and in nonulcerous duodenal syndromes. Barium treatment was not successful in patients presenting advanced changes in the duodenum, callous and deforming ulcers and considerable thickening of the duodenal walls. Good results were obtained in duodenitis and periduodenitis accompanying cholelithiasis. Treatment was found especially valuable during the acute seasonal stages of duodenal ulcer (spring and fall).

 *Treatment of Hemoptysis by Subcutaneous Emphysema N Gonzalez de Vega and D Castilla Perez—p 485

Treatment of Hemoptysis by Subcutaneous Emphysema.—Gonzalez de Vega and Castilla Perez report satisfactory results from the production of a subcutaneous emphysema in the inferior half of the thorax, by means of subcutaneous injections of air, in the treatment of tuberculous hemoptysis. The injections in their cases were given in amounts varying from 200 to 300 cc of air and performed at the posterior axillary line at the level of the eighth, tenth or eleventh ribs. The authors used a pneumothoracic apparatus, but identical results are obtainable from the use of a Potain insufflating pump or of a large syringe. The method is simple in its technic, efficient in its results and harmless. The only necessary precaution is to inject the air in the inferior half of the thorax in order to prevent the formation of either mediastinal or cervical emphysema. The four patients treated by the authors were suffering from pulmonary tuberculosis of either exudative or dense fibrous type. The subcutaneous injections of air were the only treatment given to two patients, those who were seen by the authors shortly after the appearance of hemoptysis. The remaining two were seen by the authors one and three days, respectively, after the appearance of the hemorrhage. They had been given during those days a hemostatic preparation without any favorable effect. In all four cases the hemoptysis was checked immediately after the injection of air or a few hours later.

Extreme Variations in Protein and Fat in Diet in Diabetes Mellitus—In order to determine whether, besides insulin and the usual dietary measures, there are other possibilities that permit a modification of the diabetic metabolism, von Drigalski kept eleven patients with severe or average diabetes mellitus under observation for about eighty days. For sixty days the patients received the usual dietary treatment and after that were given for twenty days diets containing an abundance of proteins or a restricted amount of proteins. The author did not observe any therapeutic effect during this phase of treatment, and in one case he observed an exacerbation. This contradicts the results obtained by other investigators, but he thinks that this contradiction is due to the fact that the other investigators instituted those diets during the first phase of treatment, and he believes that the efficacy of the diets at that time is the result of the strict diet as such. Once the improved tolerance has reached a state of rest and the metabolic condition a certain constancy, the diets with extreme variations are no longer effective. Nevertheless, these diets may prove of practical value in patients who get tired of one diet. The change to another diet keeps the patient in metabolic equilibrium. Moreover, a diet with a high protein content appeases the appetite readily and thus is of value in the treatment of polyphagic diabetic patients. However, protein sensitivity should be watched for.

Action of Products of Roasting on Gastric Secretion—Heupke points out that the flavors produced by roasting are found in a variety of foods. He investigated the gastric secretion following the intake of roasted and unroasted coffee, of roasted and boiled meats and of other foods. He never observed an increase in the acidity values traceable to the roasting substances alone. In several instances it appeared that the hydrochloric acid secretion was reduced, but in the majority of cases there was no noticeable modification, and the author concludes that the roasting products influence the acid secretion only slightly or not at all. Nevertheless, it cannot be denied that the roasting products do exert certain physiologic actions. Maier was able to show that they increase mental alertness. They also reduce fatigue and prostration and counteract the sensation of hunger. Thus the roasting products influence the nervous system, particularly the sensory nerves. Except for a slight increase in the peristalsis, they have only a slight effect on the motor nerves.

Influence of Aminoacetic Acid on Creatinuria in Goiter—Gros points out that the creatinuria existing in certain forms of myopathy has been influenced by the administration of aminoacetic acid. Since there are a number of disturbances (among them exophthalmic goiter) in which an impairment of the muscles is not evident but in which creatinuria exists nevertheless, the author decided to investigate the effect of aminoacetic acid on the creatinuria of these conditions. He made his studies on nine patients with exophthalmic goiter. The daily elimination in the urine of creatine and of creatinine was determined. In accordance with former tests, a reduction in the creatinine content of the urine and a more or less severe creatinuria was observed in all cases. Following the administration of aminoacetic acid the creatinuria increased by 100 per cent or more. The author concludes that in disorders with different clinical aspects there may exist a syndrome of disturbances in the muscle metabolism, which is probably caused by similar anatomic and functional disturbances. The aminoacetic acid medication did not exert any influence on the basal metabolism of the patients with exophthalmic goiter.

- *Hearing and Speech Disturbances II Loebell—p 619
- *Inguinal Sterilization Menge and F Schultze-Rhonhof—p 621
- Inflammation of Optic Nerve and Choked Disk, Particularly as Regards the Early and Erroneous Diagnoses Heine—p 624

Hearing and Speech Disturbances—Loebell shows that severe impairment of hearing is the cause of some forms of stammering and particularly of lispings. This was clearly demonstrated in cases of sigmatism. The author thinks that the hearing capacity should be examined in patients with speech defects and, if necessary, the ear should be treated. The prognosis of certain forms of stammering is largely dependent on the ear defect, that is, it is favorable or unfavorable to the extent to which the defect in hearing can be improved. The author illustrates this with a case of vowel stammering with interdental sigmatism and a case of stammering with tachylalia.

Inguinal Sterilization—Menge and Schultze-Rhonhof state that inguinal sterilization with extraperitonealization and suturing of the partially resected uterine tubes into the inguinal canals was first suggested by Menge in 1899. They think that it is the only surgical method for the sterilization of women that has never failed. Their observation covers 107 cases. In some of these women the operation dates back twenty-six years and in others only two years. In all women who could be reached (ninety-three in all) the operation had resulted in permanent sterility. The authors emphasize that only Menge's original method insures against failure and that its modifications, like all other methods of sterilization, have been known to fail at times. They consider the "extended Alexander-Adams operation" an effective method to insure the permanent extraperitonealization of the uterine tubes in the inguinal canals. They further emphasize that Menge's operation never causes difficulties, for all intraperitoneal complications, such as peritonitis and adhesions, are obviated, and there is no danger of ileus, a complication that has been known to follow other methods of sterilization. Other advantages of Menge's operation are that its technique is simple, that it can be completed in a short time and that it can frequently be performed under local anesthesia. The authors advise that the extraperitonealization and suturing of the resected tubes should be preceded by a forward drawing of the round ligaments (up to their proximal end) from the opened peritoneal cone. If this has been done, it is unnecessary to exert traction on the delicate and soft tubal tissue. Exact knowledge of the topography of the external inguinal ring and of the entire inguinal canal is highly important for the success of the operation. The method has the disadvantage that it cannot be used in case of extensive adhesions in the small pelvis with retrofixation of the uterus. However, this disadvantage is of slight practical importance, because such women as a rule, are already sterile. Moreover, thin membranous adhesions in the small pelvis can generally be detached from the inguinal canal by the digital method.

- Hormonotherapy of Atrophy in Nurlings P Roboz—p 240

Plasma Phosphatase in Normal and Rachitic Children—Andersen reviews former studies on plasma phosphatase and describes his own investigations. In children without signs of bone disease he found that in children up to 3 years of age the average value is 0.25 unit and the marginal values are 0.14 and 0.34 unit, and in children between the ages of 3 and 13 years the average value is 0.15 unit and the marginal values are 0.06 and 0.26 unit. In twenty-one children with rickets (aged between 3 and 27 months) he found the average plasma phosphatase value to be 0.86 unit and the marginal values 0.42 and 1.41 units. He concludes that phosphatase values under

0.3 unit are not increased, that values between 0.3 and 0.4 unit may be increased and that values in excess of 0.4 unit are definitely increased. Thus 0.3 unit may be regarded as the lowest limit of pathologic values. The author observed also that antirachitic treatment produces a reduction in the plasma phosphatase in children with rickets, so that normal values are reached. The reduction in the phosphatase is slower than the increase in the calcium and phosphorus values, and it appears that the phosphatase values adhered more closely to the clinical improvement. There seems to be no direct connection between the absolute phosphatase and calcium values, however, there is a certain relationship between the phosphorus and the plasma phosphatase values, so that in case of low phosphorus values there are, as a rule, high phosphatase values and vice versa. The severity of rickets seems to have no influence on the absolute phosphatase values. In severe cases of rickets there may be high as well as comparatively low values of phosphatase. The author assumes that an increase in the phosphatase without the simultaneous existence of the clinical signs of rickets may indicate a latent D avitaminosis. Moreover, he thinks that the determination of the plasma phosphatase may perhaps prove helpful in detecting the optimal dose of vitamin D in the treatment of rickets.

- *Gonadotropic Factors of Urine During Menopause A Lipschütz—p 532
- Abnormal Quantities of Nitrogen (N_2) in Blood of Patient with Pulmonary Emphysema G Leiner—p 535

Nycturia and Gastric Ulcer—Jores and Beck maintain that the quantitative relationship of day and night urine is not the result of night rest and sleep but that the normal restriction of the elimination of urine during the night is a definitely established rhythm, conditioned by mechanism in the central nervous system. That this is so was proved in tests on persons who worked during the night. Observations on these persons indicated that neither sleep nor the lack of fluid intake is the cause for the nocturnal limitation of the secretion of urine, but that hormonervous mechanisms, rhythmic processes, are the determining factors. The authors cite investigators who observed inversion of this normal type of water elimination. The inversion of the normal type is especially frequent in cardiac and renal diseases accompanied by disturbances in the water exchange. Other conditions in which the nocturnal inhibition of diuresis has been found absent and a nycturia present are cerebral syphilis, narcolepsy, epilepsy and emaciation. After the authors accidentally observed nycturia in patients with gastric and duodenal ulcer they decided to study the relations between these two conditions. Tests on thirty-one patients in whom the diagnosis of ulcer had been corroborated by roentgenoscopy disclosed the presence of nycturia in twenty-two, in seven others the nocturnal quantity amounted to more than two thirds of the total daily quantity, and in the remaining two the elimination of the urine was normal. Control tests on twenty-four patients with various disorders disclosed only two patients with nycturia. The authors reach the conclusion that ulcer and nycturia are two distinct manifestations of a disturbance in the hypophyseodiencephalic system. In view of the localization of the center of the water exchange in the diencephalon, the authors call attention to Cushing's observation of the occurrence of intestinal ulcers in case of tumors in that region of the brain, and to the experimental development of gastric ulcers following the injection of large doses of hypophyseal extracts, observed by other investigators. After citing two other interesting cases the authors express the opinion that nycturia is a noteworthy symptom of intestinal ulcers that developed on a nervous basis.

Gonadotropic Factors of Urine During Menopause—Lipschütz calls attention to a report by Anselmino and Hoffmann in which those authors proved that Evans' "synergistic" gonadotropic factor of the anterior lobe of the hypophysis appears also in the urine of castrates and of women in the

menopause, and then he discusses his own studies on this problem. He cites his comparative experiments on guinea pigs and rats with the gonadotropic principle of the anterior lobe of the hypophysis. These tests indicated that the so-called synergistic factor of the anterior hypophysis, which appears also in the urine of menopausal women, is identical with the follicle sensitizing factor. The estrogenic factor should be differentiated from it. Moreover, he thinks that the complete gonadotropic complex probably contains three water soluble hormones, namely, the estrogenic, the follicle-sensitizing and the luteinizing factors.

- *Life Saving Action of Ovarian Preparations in Severe Hemorrhages in Patient with Hemophilia K Franke and S Litzner—p 520

Dilation of Bronchial Stenosis by Laminaria Pencils—Amersbach shows that the expansible laminaria pencil can be employed for the dilation of bronchial stenoses. This dilation makes it possible to enter the bronchi with wider tubes and it also facilitates the manipulation of instruments in the bronchi. The inclusion of an iron core in the laminaria pencil allows roentgenologic localization of the pencil. The author shows that this is especially helpful in determining the localization of the pencil relative to the foreign body that is to be extracted. He thinks that the laminaria pencil will prove helpful likewise in the dilation of tracheal stenoses.

Diagnosis of Tumors of Carotid Gland—Schmieden and Mahler review the literature and list the following points, which Klose mentioned in 1922 in connection with two cases observed in Schmieden's clinic, as a basis for the diagnosis of tumors of the carotid gland: (1) it is localized at the bifurcation of the common carotid artery, (2) laterally the tumor can be moved readily, but vertically it is impossible to move it, (3) it is oval, its surface has flat humps and it is of a firm, elastic consistence, (4) there is expansive pulsation with systolic sounds, but both disappear on compression of the common carotid artery, (5) there are protrusion of the pharyngeal wall and paralysis of the vocal cords, (6) the pupil on the diseased side is contracted in some cases, (7) the growth is slow, (8) palpation of the tumor is painless. Other reports have appeared and all authors agree that the diagnosis of tumors of the carotid gland is difficult. Occasionally a tumor of the carotid gland is discovered, when the disorder has been diagnosed as something else, and, on the other hand, tumors in the bifurcation of the common carotid artery have been found to be of different origin. The authors think that, if the foregoing symptoms are observed in case of a tumor in the region of the cervical triangle at the level of the carotid bifurcation, a tumor of the carotid gland should be thought of. Probability diagnoses that are often made are aneurysm, lymphoma, lympho-sarcoma, aberrant struma, cyst of the bronchial canal, branchiogenic carcinoma, Hodgkin's disease or cold abscess. The fact that cases of bilateral tumors of the carotid have been observed and that they occur even in infants and small children is another factor that makes the diagnosis more difficult. The question of the malignant condition of the carotid tumors has not been definitely answered as yet.

Action of Ovarian Preparations in Hemophilia—Franke and Litzner report the history of a boy, aged 12, who since the third year of his life suffered from severe hemorrhages. Extravasations developed in various joints and later renal hemorrhages set in. The boy had been treated for several years with hemostyptic tablets containing vitamins A, B, C and D and calcium phosphate. During the severe renal hemorrhages he was given not only this vitamin preparation but other hemostyptics. In an especially severe renal hemorrhage, all these preparations proved ineffective. The boy's life was in danger and it was decided to try an ovarian hormone preparation. The patient was given an intravenous injection of 1,000

units and after one hour he complained of drawing pains in the region of the right kidney. Then colic developed and the urine contained clotted blood. On the following day the injection was repeated and was again followed by colic and by the evacuation of blood clots and normally colored urine. After that there was no recurrence of the renal hemorrhage and another injection three days later caused no pains. Coagulation time and bleeding time were now greatly reduced. The blood status, hemoglobin content and erythrocytes improved rapidly under the influence of iron therapy. The authors are investigating whether the oral administration of ovarian hormone preparations is suitable for the continuous treatment of patients with hemophilia.

Physiology and Pathology of Bilirubinemia—Fellingner and Pfeleger studied the behavior of serobilirubin in healthy persons as well as in a large number of patients with various disorders. The bilirubin content of the serum was determined while the persons were fasting, during starvation and following the intake of food. The authors found that during starvation the serobilirubin is always increased in healthy persons as well as in those who are ill. The increase develops rather slowly and does not exceed certain maximal values. Following the intake of food, the bilirubin values show a noticeable reduction. The lowest values are not reached until several hours after the meal. It was demonstrated on a large number of patients that persons with high initial values of serobilirubin show the most pronounced fluctuations. However, patients with certain hepatic disturbances are an exception to this rule. The authors think that impairment of the liver cells by hunger, rhythmic changes in the function of the liver and a connection of the serobilirubin fluctuations with the bile secretion help to explain the described observations. Theoretical reasoning and experiments indicate a causal connection between serobilirubin and bile secretion.

Barbituric Acid and Thyroid—On the basis of observations on patients and of animal experiments, von Zárday and Weiner conclude that there is an antagonism between the hormone of the thyroid and the barbituric acid preparations, which does not include other soporifics. The cause of this elective antagonism is the fact that both the barbituric acid preparations and thyroxine have their point of attack in the cells of the diencephalon. Because of this antagonism, patients with thyrotoxicosis as well as persons with a hyperthyroid-sympathicotonic constitution require larger doses of barbituric acid preparations to go to sleep than do other persons. In order to determine the correct dosage, it is advisable to give attention to the somatic and psychic signs that permit detection of the neurohormone status of the patient.

Tubercle Bacilli in Gastric Irrigation Fluid of Children—Hacker and Wallis point out that demonstration of tubercle bacilli in the sputum is rather difficult in young children because they swallow rather than expectorate the sputum. For this reason, investigators have resorted to examination of the fluid obtained by gastric lavage. The authors examined the gastric irrigation fluid of fifty children for the presence of tubercle bacilli by means of the animal experiment. The time elapsed between the injection of the infective material and the manifestation of the pathologic process varied between sixteen and seventy-six days, the average length being forty days. The experiments revealed that fifteen of the total number of fifty children had an "open" tuberculosis. It was found also that younger children have a positive bacillary test much more often than the older children. However, the greater frequency of the positive tests is not so much the result of the lesser age as such but is rather due to the fact that during this age primary lesions are more frequent which in turn results in a greater tendency of this age group to open forms of tuberculosis.

Action of High Tension Electric Current (Alternating Current of from 1 000 to 3 000 Volts) at a Frequency of 50 Cycles on Normal and Alcoholized Rabbits E. O. Manoiloff —p. 495

Hormone Properties of Pineal Body—Engel says that some investigators consider the pineal body an endocrine gland while others deny its endocrine function. He describes studies on the influence of pineal extracts on sexual development, the sex hormones, the gonadotropic hormones of the anterior lobe of the hypophysis and the growth of tumors. He calls attention to the toxic actions of the pineal extracts. A survey of the various actions of the pineal body discloses, in addition to a somewhat indistinct action on the processes of cornification and on the growth process, an inhibiting effect on two important hormones of the anterior lobe of the hypophysis, namely, the hormone effecting maturation of the follicle and the hormone producing luteinization. He describes a test for the demonstration of the antigonadotropic hormone of the pineal body and reports his studies on the hormone content of the pineal glands of a number of persons of various age groups, who had died from various disorders. He found that from 29 to 40 rat units was the average antigonadotropic hormone content, but in two cases he found as high as 60 rat units. He studied the antigonadotropic hormone content of the blood and of various organs. These investigations indicated the organ specificity of the substance and its probable transportation by the blood. In discussing the chemical properties of the antigonadotropic substance of the pineal body, the author states that it can be extracted readily by alkaline aqueous solutions from the dry acetone powder. Alcohol, ether or acetone extracts have always proved ineffective. The hormone is not thermostable. Ultrafiltrates retain their antiluteinizing action but apparently not the action directed against the maturation of the follicle. In the course of acid extraction the greatest part of the efficacy is destroyed. The author thinks that the hormone of the pineal gland may eventually find clinical application.

Paravertebral Alcohol Injection in Angina Pectoris—Mandl points out that paravertebral injection interrupts the ramus communicans and thus the pain conduction to the visceral organs. The injection of anesthetics proved helpful in surgical anesthesia and for differential diagnostic purposes. It seemed desirable to use a substance that would have a more lasting effect, and alcohol was chosen. The author employed the paravertebral alcohol injection in a large number of patients and stresses that the route of injection should be anesthetized and that the alcohol should be deposited from 0.5 to 1 cm away from the vertebral column. He injects from 2 to 5 cc of a 70 or 80 per cent alcohol solution. He enumerates the conditions in which paravertebral alcohol injection is advisable, giving especial attention to angina pectoris. He observed favorable effects of long duration in 50 per cent of the cases of angina pectoris, in 10 per cent of the gastric crises, in 90 per cent of the cases with severe pains in the region of the biliary tract and of the kidney, in 90 per cent of the cases with herpes zoster and in 75 per cent of the vasomotor disturbances. The method was ineffective in spondylarthritides. The author thinks that in disorders in which a surgical intervention may eventually be considered (angina pectoris) the paravertebral alcohol injection should always be tried first, the more so since its results are not much inferior to the surgical interventions on the sympathetic.

Action of High Tension Electric Current—Manoiloff describes studies on rabbits, which demonstrated pathologic changes in the nerve cells of rabbits that had been influenced by alcohol. He found that the action of the high tension electric current results in fatality much oftener in alcoholized rabbits than in those that have not been treated with alcohol. He concludes that persons who work with the high tension electric current are always exposed to danger and should avoid the abuse of alcohol.

 Necessity of Removing Adnexa in Operation of Carcinoma of Body of Uterus E Wallbruch—p 865

Gonadotropic Hormones in Chorionepithelioma—Spitzer points out that surgical manipulations may lead to metastasis of chorionepithelioma and that consequently radiologic therapy has been recommended by many authors. Assay of the content of gonadotropic substance in the urine in cases of chorionepithelioma and of cystic mole has been found valuable in diagnosis as well as in determining the efficacy of treatment. Most studies so far have been concerned with the change in content of gonadotropic substance following the surgical removal of chorionepithelioma and not with that following radiologic treatment. The author investigated the latter. A woman, aged 26, with vaginal chorionepithelioma was subjected to a combination radium and roentgen treatment. Reactions II and III of the Aschheim Zondek test, which had previously been positive, became negative. This and the negative histologic results of a biopsy, which was done following the irradiations, indicate that the radiologic treatment effected cure.

 Investigation of Vitamin E Content of Vibeta Alleged Vitamin E Concentrate P Schoorl—p 2086

Tropical Sprue, Pregnancy and Eczema—Van Steenis reports thirty-eight cases of sprue in women thirty-three of whom were married and in the child-bearing period. Twelve of these occurred during pregnancy. Eight were primary cases of sprue during pregnancy and four recurrences of sprue pre-existing during pregnancy. As a rule, the symptoms appeared after the sixth month. General recovery or marked improvement set in after delivery. The symptoms of sprue of pregnancy do not differ materially from those of other cases. As a complication in four of the twelve cases, eczema appeared during the seventh and eighth month respectively of pregnancy and ten days and two months respectively after delivery. In the first three patients it was generalized on the trunk, the extremities and the genitalia, and it subsided shortly after delivery. The author states in conclusion that eczema is not a common complication in sprue or in pregnancy.

Operative Treatment of Perforated Ulcer—Schilling reports 265 cases of perforated gastric and duodenal ulcers collected from the two surgical departments of the Ullevål Communal Hospital in Oslo and in which operation was performed between 1912 and 1934. The gastric ulcers made up two thirds and the duodenal ulcers one third of the material, including the latter, 80 per cent of the ulcers were located near the pylorus. The majority of perforations, 85 per cent, were found in men. A distinct increase in the number of perforations was noticeable in men particularly in young men. There were seventy-one cases from 1912 to 1922 inclusive and 194 cases from 1923 on. The rate of perforations among women on the other hand, was lower in the second period than in the first. The treatment was the same in the two departments. The operation was begun with an incision in the right iliac fossa then suture of the perforation and as a rule gastro-enterostomy (in 79 per cent), lavage through both incisions and closure without drainage were performed. Ulcers located far from the

pylorus and those in debilitated patients were treated by suture alone. The results were exceedingly good, the mortality rate being 28 per cent within the six-hour limit and 74 within the twelve-hour limit.

Treatment and Prognosis of Hypernephroma—Bull reports thirty-seven cases of hypernephroma, twenty-one in men and sixteen in women, 73 per cent of the patients ranging in age from 40 to 59. One female patient was but 18. There were twenty-six nephrectomies with two deaths (7.7 per cent), one from uremia (ether anesthesia) and one from pulmonary embolism a few hours after the operation. There were twenty extraperitoneal and six transperitoneal nephrectomies. The justification of always commencing the operation with ligation of the renal vessels to prevent, if possible, metastases is discussed. No satisfactory results were obtained by the use of roentgen and radium irradiation. Operation was performed on twenty-three patients more than three years ago, eleven of these, or 47.8 per cent, have lived for more than three years but only five of these eleven are free from recurrence. Twelve, eight, eight and three and one-half years after the operation, and two, free from recurrence after seven and four and one-half years, are dead, thus seven of the twenty-three, 30.4 per cent, are free from recurrence. Two died of recurrence after six and three-fourths and four years, and two are living with recurrence after three and five-sixths and twelve years. The patient with local recurrence after twelve years had a large cystic growth weighing 107 Kg. Thirteen nephrectomized patients, who subsequently died of their recurrences, lived from two and three-fourths months to six and three-fourths years, an average of at least two years after nephrectomy and at least three years from the first clinical symptoms. Ten non-nephrectomized patients lived from one to three and one-half years, or an average of two years from the first symptom. One patient with metastasis of the lymph nodes the size of a walnut is still living after thirteen years. All patients with thrombosis of the renal vein (five) have died of recurrences. Atypical hypernephroma gave a worse prognosis than the typical cases. One patient with metastasis of the femur was free from recurrence nearly two years after disarticulation of the femur.

Lipogranuloma—Harbitz defines lipogranuloma as a special foreign body inflammation of the adipose tissue with characteristic granulation tissue and development of oil cysts lined with polynuclear cells or syncytia. These cysts are later transformed into serous cysts surrounded by acellular hyaline connective tissue, which may become calcified, or the cysts may obliterate to solid fibrous or calcified lumps with histologic resemblance to psammoma bodies. They have then a characteristic roentgenogram showing ring-shaped or solid small round calcifications most frequently situated in the subcutaneous fat tissue. The author's material consists of seventeen cases of lipogranuloma in the breast and nineteen cases in other localities. Many of the circumscribed lipogranulomas were removed on suggestion of a malignant tumor.

 *Blood Picture and Sedimentation Reaction in Inflammatory Diseases of Eye Cn H Sjögren—p 262

Blood Picture and Sedimentation Reaction in Inflammatory Diseases of Eye—Sjögren made an examination of the blood in 200 cases of inflammatory disorders of the eye, 153 of endogenic and 47 of exogenic origin, and carried out the sedimentation reaction in 352 cases, 294 of the endogenic and 58 of the exogenic kind. He says that, while the sedimentation values were increased in about 50 per cent of the endogenic cases shifting to the left occurred in only about 11 per cent, which agrees with the known fact that the latent chronic infections which are the chief etiologic factors in diseases of the eye are more surely reflected in the sedimentation reaction than in the hemogram. A definite relation between diseases of the eye on the one hand and the blood picture and the sedimentation reaction on the other cannot be confirmed. In about half the cases neither the eye disturbance nor the underlying focus in the body is expressed by certain pathologic changes in these reactions. The reactions afford no evidence for differential diagnosis and are of no prognostic significance.

RESEARCH IN PSYCHIATRY

CHAIRMAN'S ADDRESS

H DOUGLAS SINGER M.D., F.R.C.P. (LOND)
CHICAGO

An excellent review of modern trends of research in connection with psychiatry is contained in the Problem of Mental Disorder¹ published by the National Research Council. Some idea of the relative volume of investigations in the different fields can be gained from the report of Whitehorn and Zilboorg² for the Committee on Research of the American Psychiatric Association. Using as a basis of comparison the number of pages in three American journals (*American Journal of Psychiatry*, *Archives of Neurology and Psychiatry* and *Journal of Nervous and Mental Disease*) devoted to particular topics of research during the decade 1921-1930, they divided the material into (1) clinical studies, which decreased from 1,622 in the first five years to 1,492 in the second five years, (2) psychologic studies, which increased from 817 to 1,923 pages, (3) physiologic studies, which showed an increase from 247 to 404 pages, (4) studies dealing with the relation of psychiatry to medicine, sociology, law, and other subjects and (5) miscellaneous studies. Both of the last two categories showed some slight decrease in the second half of the decade.

These observations suggest that there has been a decline of activity in clinical studies, attention having been diverted to more abstract psychologic and more concrete physiologic methods. The exact degree of change is of course not reflected in the number of pages of printed material, my own opinion is that the swing to these other fields of study has been much greater than is thus presented. In any case the change is sufficiently great to justify some consideration of its significance and its bearing on progress in psychiatry.

One of the principal points I wish to stress concerns the importance of clinical research, and I shall discuss the relations that exist between clinical psychiatry and the two types of research included by Whitehorn and Zilboorg under the captions psychologic and physiologic. Though it may be unnecessary, it seems well to stress that what I shall say is in no sense critical of the quality of the work in these fields that is being done, nor does it belittle such applicability as the results may have in the practical treatment of patients.

It does, however, seem worth while to raise the question whether these types of study are strictly psychi-

atric, even though they yield results valuable in the clinical application of psychiatry. The answer to this question will necessarily turn to some extent on the interpretation of the word psychiatry. The suffix of the word (Greek, iatros) means treatment and at once indicates that psychiatry belongs in the practice of the art of medicine. When one attempts, however, to specify the particular forms of human illness with which it deals one is confronted with a difficult problem. Probably the answer that would be most satisfactory to psychiatrists would be that it includes those forms of illness which present evidences of disturbance in the higher levels of integration of the organism, particularly those into which enter the phenomena of consciousness. That such a definition is too broad, however, becomes clear from the consideration that adjustments at this level are concerned in practically all forms of illness. The body reacts as a whole even to disease of a particular organ, and there are evidences in all illness of disturbance in integration at all levels. I should answer this by saying that psychiatry permeates, or is an aspect of, all medicine. If one attempts to restrict the definition to forms of illness in which such disturbances are primary—that is to say in which disorder of the lower levels is secondary to derangement at the highest levels—it is my belief that sooner or later much of the traditional field of the psychiatrist, including most of the psychoses, will be excluded by the definition. Even the psychoneuroses, full credit being given to the significance of modern dynamic interpretations, need some additional factor for their full understanding, a factor that was expressed by Freud as a constitutional defect. The nature of this defect cannot be defined more exactly, but it may be suggested that it is apt to be found to depend on disturbance of function at lower levels, perhaps even the cellular level.

PSYCHOLOGIC AND PHYSIOLOGIC METHODS

The suggestion that psychologic research is not psychiatric may be confusing, the view has practical value in considering methods of research, however, though it needs elaboration if it is not to be misunderstood. I would compare the relations between these two disciplines with those which obtain between physiology and medicine in general. Physiology may furnish explanations of the symptoms of disease, but it does not explain the disease even when it provides means of importance in therapy. Insulin is today the best means available for combating the consequences of diabetes, but it is not a remedy for diabetes and does not furnish information as to the ultimate cause of the disease. Psychology, including the special technics of psychoanalysis, does afford an understanding of the mechanisms concerned in the formation of symptoms but cannot supply a complete explanation for the illness expressed in the symptoms. Dynamic psychology can explain the mechanism of a paranoid attitude or a com-

Read before the Section on Nervous and Mental Diseases at the Eighty-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1935.

1. *The Problem of Mental Disorder*. New York: McGraw-Hill Book Company, 1934.

2. Whitehorn, J. C. and Zilboorg, Gregory. *Present Trends in American Psychiatric Research*. Am. J. Psychiat. 13: 303 (Sept.) 1933.

pulsive phobia but cannot furnish the reason for the adoption of one of these modes of reaction rather than of some more satisfactory form of response. In other words, psychologic studies can explain the form but not the fact of illness, and it is with the latter that psychiatry is ultimately concerned. I do not wish to stress this view unduly, for I recognize that in many cases it is more important therapeutically to understand the mechanisms and their relations with situations to be faced than to know the nature of a deviation in construction of the organism which may not be susceptible of modification when discovered. On the other hand, one should not rest content with even the most complete psychologic interpretation of symptoms if there is any prospect that the underlying cause of the illness may be remedied, and it is this which is the prime objective of psychiatric research.

To express this in another way, therapy based on psychologic principles, valuable as it is, must always remain symptomatic. The danger in the situation is that complaisance in the accomplishments achieved by these methods has and will result in neglect of more fundamental pathologic conditions. This I believe to be especially important in regard to the psychoses, as will become evident from what is to follow.

Turning now to the development of physiologic methods, it may at first glance appear that this type of attack is more directly in line with what I have in mind. However, I would suggest that somewhat similar differences exist here to those which I have already indicated for psychologic methods. A further objection to the use of physiologic methods at the present time consists in the fact that psychiatric knowledge is not ready for it. The only basis for correlations now available is the form of the psychosis, which is a psychologic and not a psychiatric basis. Correlations are being made with types of behavior—personality types—and not with disease entities.

Psychiatry is essentially a clinical subject. Advances in other fields of clinical medicine have led and not followed laboratory discoveries. It seems logical to conclude that this story will be repeated in psychiatry. One of the first desiderata in clinical research is a scientific classification of the phenomena observed. The classification of mental illnesses today is, to use the homely simile of Hughlings Jackson, that of a market gardener in regard to plants. Outstanding surface phenomena are the main basis of grouping. It is necessary to find fundamental and essential elements in order to achieve a classification comparable to that of the botanist. It may be that such criteria are already available but not yet grasped, it may be that they are still to be discovered. Much has been gained from the clear recognition of dynamic factors, at least from the point of view of therapeutic approach, with these as clues it may be that the still elusive principles underlying disease entities will emerge from these methods, but they are not yet evident.

Though it may seem to be a regression, I urge that there is still need of a continuation of the ancient methods of clinical observation, modified and elaborated to comply with advances already made. Probably no one today will accept in its entirety the classification formulated by Kraepelin. Even he, before his death, recognized that the prognostic criterion he used so largely in his earlier efforts failed to provide the goal he sought. Yet it is not questioned that course and outcome are individual characteristics of disease processes. I believe that the aim was sound and may still lead to success, if its implications are considered in the

proper light. The end results of a disease do furnish clues as to the core of the damage or defect. This is well illustrated by the results of studies of aphasia, define the functions that have been destroyed and it becomes possible to formulate the location of the damage. In the same manner, painstaking study of end results in psychiatry by clinical methods will furnish clues to the parts that are damaged. Methods must be devised for isolating and defining functions that are permanently deficient, both in the psychoses and in the psychoneuroses. Since one deals with reactions of the total organism, these methods must be such as to test the behavior of the patient in situations resembling those encountered in life and not merely such as to investigate the function of some organ or system. There is no justification at present for assuming that any part physiologic action, hormonal, metabolic or any other, can be accepted as an indication of the existence of particular changes in biologic reaction, though it is possible that later such may be found.

DIFFERENTIATION OF PSYCHOSES

To illustrate the points I am trying to make, it seems well here to discuss briefly some of the forms of mental illness that are too often dealt with as if they were nosologic entities. First may be considered the concept of oscillations of mood as defining a particular form of mental illness, called by Kraepelin manic-depressive. This he considered a fundamental characteristic distinguishing these psychoses from types that tended to end in a peculiar form of deterioration.

Manic-depressive reactions may be considered from two points of view, the one psychiatric and the other psychologic, as I would express it. (1) the seat and nature of the condition causing the disorder in mood, (2) the character of the behavior that expresses the disturbance in mood. It is difficult to avoid the conclusion that, in much of what is written and taught, these two aspects of the problem have been confused. Brief consideration of clinical facts reveals that swings of mood of this kind occur under widely different conditions, some including disease within the body, others involving mainly environmental situations to be adjusted to. For example, there are (a) the manic-depressive psychoses without discovered pathologic changes within the body, (b) swings of mood associated with bodily disease, which is not confined to the nervous system—dementia paralytica, arteriosclerosis, diseases of the thyroid gland, heart disease, and so on. The occurrence of this one feature under such widely different conditions seems to justify the conclusion that it is not a single disease but rather a particular location of damage or defect in the structure of the integrating machinery of the body, probably at a vegetative level. From the point of view contained in the second category mentioned, that of the type of behavior exhibited, however, there is also a wide variation of the form in which the mood is expressed, which may or may not have certain relations to the particular form of the disease that is present, but which more often seems to depend on the type of personality of the patient. One finds oscillations of mood labeled from this point of view as manic-depressive, schizophrenic, delirious and paranoid. There are thus presented numerous problems for psychiatric clinical investigation, and the doubtful value of correlations with physiologic study are strongly emphasized.

Turning now to the group of psychoses labeled schizophrenia or dementia praecox, one finds that somewhat similar comments apply. Here, however, the

problem is even more complex. The occurrence of deterioration is today more or less ignored as a criterion for classification, and inclusion in the group depends on the observation of patterns of behavior that are characterized by excessive use of occult or highly symbolized responses—caricatures apparently of those features of human behavior which render social life possible—the repressive and substitutive types of reaction. One need not question the propriety of classifying psychologically such behavior in one class, but few will disagree with the remark that it is not a nosologic or psychiatric unity. Ignoring the occurrence of schizophrenic behavior in many different forms of disease of the body, just as was true of the manic-depressive reactions, and considering only the group of schizophrenia as currently defined, the variability in course, manifestations and outcome is so great that it seems impossible to consider this group as representing a single disease process. From the point of view of course alone it is well recognized that some cases represent apparently swings of mood with schizoid coloring—currently spoken of as schizophrenia with manic-depressive features, some are acute reactions apparently to external environmental situations, and end in complete recovery, some cases terminate with the phenomena of more or less severe “deterioration.” Too little attention has been given to these terminal states, all show some loss of capacity for integrated behavior, but the capacities lost are not the same in all. I would stress particularly the psychiatric importance of devising methods for defining what has been lost for this I believe will furnish criteria for splitting up this enormous group and possibly even for learning the seat of the damage. In still other cases there are the well known disturbances in muscle tone, which surely cannot be ignored in the effort to establish disease entities.

Throughout all the forms, it is true runs the common factor of the character of the behavior. It seems worth while to insist that this is a psychologic distinction and not a psychiatric one. It concerns not the disease or defect that is present but rather the kind of person who is ill.

From these considerations it seems clear that there is no valid basis in these psychologic differentiations for correlation with special methods of laboratory research, physiologic or pathologic. Healthy persons healthy in the sense that their behavior enables them to meet more or less satisfactorily to themselves and to society the conditions of social life, all present a combination of varying proportions of the factors that have just been considered in the two large categories of named psychoses. All show more or less evident cyclic swinging of mood, the cycles being interrupted, it is true in their regularity by demands for reaction to situations of biologic importance in the surroundings. In all there are more or less well marked the mechanisms of repression, substitution and symbolization which when exaggerated for any reason, constitute the mechanisms underlying the psychologic classification of schizophrenia.

The situation is much the same in regard to the psychoneuroses. Until the advent of modern dynamic concepts of behavior, this group was even less studied than that of the psychoses. Except for a very superficial sorting, little attempt had been made to classify these heterogeneous clinical pictures. There is growing a method of subdivision that is based, even more than is true of the psychoses, on dynamic psychology. This

method of classification has decided advantages from the point of view of therapy. Nevertheless, it is psychologic rather than psychiatric. Included among these conditions, I am convinced, are some which clinical study will demonstrate to possess characteristics, corresponding with course and outcome, that would justify psychiatric subdivision, even if the majority must be grouped in a psychologic manner.

FUNCTION OF CLINICAL RESEARCH IN PSYCHIATRY

The statements I have made are certainly not new and probably will be accepted, though perhaps sometimes grudgingly and with reservations due to personal interests and orientation, by all engaged in teaching and research in psychiatry. The formulation in this way is the outcome of an effort to outline for myself the aims and meaning of psychiatric research. I have asked myself: Why do certain conditions give rise to a mental illness, whether psychosis or neurosis, in one person and not in another? Is one to rest satisfied with such vague generalizations as constitutional deficiency or endocrinopathy? Are such factors as lack of courage and lack of energy, regression to a lower level of behavior and retirement to a world of fantasy explanations or are they merely methods of describing what is observed? To me it seems that the prime function of psychiatric research is the discovery of the mechanisms that permit the development of an illness, no matter what the precipitating or concomitant circumstances. The practicing physician will, of course, use for therapeutic purposes all available means of ameliorating and modifying favorably the symptoms of an illness for which he is consulted, even if he does not know the actual cause or nature of the illness. His observations and results, if adequately recorded and evaluated, may furnish clues to the causes. Rational therapy and improvements in methods of prevention become possible only with knowledge of the fundamental etiology. For example, advances in methods of prevention of and treatment for dementia paralytica, with its wide variety of psychologic pictures, have come only with knowledge of the causative agent, it may be emphasized here that this agent was recognized from purely clinical research long before the spirochete was discovered, improved chemical means for combating it followed. Pyrethotherapy likewise was the result of clinical observation, and research is only now endeavoring to unravel the mechanisms through which it operates.

The question will undoubtedly be raised as to what is meant by clinical research. The methods are no different in principle from those employed in other fields of medicine. I do not share the not uncommonly expressed opinion that psychiatry has graduated from the stage of description to that of interpretation. This may be true of psychology, but not of psychiatry. It may be granted that there has been careful and adequate description of the superficial manifestations and spontaneous behavior. What remains to be done concerns the devising of methods of recording the responses to controlled situations, planned with the purpose of defining exactly what integrated functions persist in any given case and what are lost or in abeyance. This is a long, tedious road, requiring persistence, imagination and ingenuity, the usual tools of research, but it is I believe the only road that will lead to a successful classification on an etiologic basis and through this to adequate correlation with other fields of research.

In this connection it seems worth while to recall the plan of analysis followed by Hughlings Jackson in his

studies of what he called the evolution and dissolution of the nervous system. This should be extended to include not the nervous system alone but all integrating mechanisms, the lowest as well as the highest. Studies of the evolution of behavior in the child, already initiated, need to be carried out in detail and by methods which are comparable with those to be used in the clinical study of patients. It seems premature to speak of regressions to a lower level of behavior until something more is known of its progressions. For the studies of dissolution one has available all the experiments of nature which make up all mental illnesses under the heading of psychiatry, including the various conditions of arrested development. This whole field has been only scratched, there is much to be done in actual tilling by devising methods for determining and specifying what is present and what is lost. These methods are essentially clinical. They need to be worked out, at least primarily, through intensive and prolonged studies of individual cases rather than through statistical methods with a mass of material.

AIR EMBOLISM

CHARLES E. HAMILTON, M.D.

AND

EMIL ROTHSTEIN, M.D.

Chief Attending Physician and Resident Physician Respectively of the
Tuberculosis Division Kings County Hospital
BROOKLYN

Air embolism is a rather infrequent complication of various surgical procedures in each of which air is permitted to enter the venous system. Cases of air embolism may be divided into two large groups—one in which air gains entry to the peripheral venous system and the other in which air enters the pulmonary venous circuit.

Air embolism resulting from air entering the peripheral circuit has been encountered in practically every surgical field. The first recorded case was reported in 1818 by Beauchesne,¹ it followed removal of a tumor from the neck and was proved at autopsy. Nordland and his co-workers² reported a series of experiments performed on this type of air embolism in dogs. They injected varying amounts of air intravenously and observed that as much as 30 cc. could be injected rapidly without any ill effects. As larger amounts were used various clinical effects were noted, characterized by alterations of the blood pressure, cardiac and respiratory irregularities, and finally death. Death was as a rule produced by amounts as large as 160 cc. If the chests of the animals were opened ante mortem the heart was found beating irregularly and ineffectually, and a churning, splashing sound could be heard. Incision into the right ventricle led to a pouring out of frothy blood and a reestablishment of the cardiac rhythm for a short time. When these animals were examined post mortem, the great veins, the right side of the heart and the pulmonary artery were found filled with air bubbles and frothy blood. When smaller amounts are injected, the air is propelled into the pulmonary circuit and gradually absorbed from the

capillaries. A similar effect is obtained when larger amounts are injected over a longer period of time. It was concluded that the cause of death in these cases was inefficacy of the cardiac action, affecting especially the right side of the heart. Owing probably to the easy compressibility of the air, the valves are not properly opened and the circulation comes to a standstill. To this is added the development of an acute hypertension of the lesser circuit due to a very diffuse capillary block of the pulmonary vessels by air bubbles.

These results are similar to those observed clinically. Small amounts of air have been observed repeatedly to be harmless in the human being when injected intravenously during transfusions and other intravenous infusions. Clinically, however, air embolism occurs when large amounts of air are allowed to enter a vein. The requirements for such an occurrence are filled when (a) a vessel is only partly severed, preventing collapse, or even in complete severance when the surrounding tissues are firm, thus preventing venous collapse and retraction, or (b) the venous pressure is negative or the air pressure positive. Probably the most frequent source of air embolism is in the region of the great veins of the neck, following thyroid and other operations. The required conditions are here fulfilled, for (a) the oblique passage of the veins through several layers of firm cervical fascia prevents immediate collapse and retraction, even when the vessel has been completely cut across, and (b) the venous pressure in the great veins of the neck is negative during inspiration, even with the patient in a prone position. When a vein is cut, the first sign is usually a hissing sound in the wound—"sifflement"—as the air is sucked in, clinical evidences manifest themselves variously depending on the amount of air aspirated—dyspnea, cyanosis, coma, cardiac arrhythmia, apnea and death. A murmur—"bruit de soufflement"—has been described over the heart, due to the churning about of the air. (This bruit is constantly found in experimental animals.)

Cases of air embolism have been reported following wounds of the neck, irrigation of the maxillary sinuses, manipulation of the intracranial venous sinuses, fractures affecting the long bones, especially the tibia, manipulation of the pregnant and puerperal uterus, and air injection into the urethra, the bladder and the peritoneum.

Mathe³ reports a case of fatal air embolism following injection of 300 cc. of air into the bladder in a case of bladder tumor. At necropsy, open vessels were found in an ulcer in the tumor, the inferior vena cava, the hepatic veins, the right side of the heart, and the pulmonary vessels contained large amounts of air and frothy blood. He wrote questionnaires to other genito-urinary specialists and found that fatalities or less serious accidents following injections of air into the urethra or bladder were not uncommon, and he advises against the use of air for this purpose.

Gording⁴ discusses the question of air embolism following puncture of, and injection of air into, the maxillary sinuses. The entrance of air under high pressure into open ulcerated vessels provides the necessary factors for air embolism, and he believes that he has successfully reproduced the syndrome in animals. He also quotes a case in which the lateral sinus was

opened and air was heard being sucked into this vessel with clinical production of air embolism

Bingel⁵ reports the air irrigation of a peritoneal pocket in a case of subphrenic abscess. The patient became comatose and a "water-wheel" murmur was heard over the heart. As a rational therapeutic procedure a needle was introduced into what was thought to be the right heart and 3 cc of air was withdrawn. The patient recovered from the air embolism.

Gough⁶ quotes and reports cases occurring in the practice of obstetrics and gynecology. Most cases follow the injection of air (with or without fluid) into the uterus during attempts at criminal abortion. Death frequently follows, and autopsy reveals air in the heart and pulmonary artery. Similar cases may follow removal of a placenta praevia, cesarean section and a douche for adhering placenta. He reports one case in which the patient collapsed and died after an apparently normal delivery. Postmortem examination revealed air in the right heart and pulmonary artery.

Most of the cases that have been reported of air embolism resulting from air entering the pulmonary venous circuit have followed artificial pneumothorax. Other causes are injury to the chest wall and lung, pleural lavage in empyema, possible passage of air through the pulmonary capillaries (or through a patent foramen ovale) when the case is one of air embolism described in the first group, and escape of air from solution in the blood (caisson disease).

REPORT OF CASES

CASE 1—S H, a woman, aged 22, Jewish, in whom the onset of tuberculosis occurred in August 1933, had a lesion consisting of diffuse caseation with cavitation, through the left lung. Artificial pneumothorax was started in October. The patient was discharged to the clinic for refills in February 1934 with negative sputums and an atelectatic lung; several firm adhesions were present. In spite of refills the lung reexpanded, owing to an obliterative fibrosis of the pleura. She was returned to Kings County Hospital in August 1934 for reestablishment of pneumothorax, which had been completely absorbed. The first trial to secure a new collapse showed no free pleural space. The next day another attempt was made in another location (August 13). The manometer showed free fluctuations, with pressures of -4 -2 cm of water. From 10 to 15 cc of air was introduced and another reading taken. There was no fluctuation. At this point the patient moaned and turned pale. The needle was withdrawn at once. The patient became intensely cyanotic, a stertor developed and then apnea. The pulse could not be felt. Irregular convulsive movements were noted. Therapy included artificial respiration, caffeine and epinephrine intramuscularly, and epinephrine intravenously. After about one-half hour there appeared a complete left hemiplegia, including facial and hypoglossal paralysis and positive Hoffmann and Babinski signs. Consciousness partially reappeared in about one hour. After six hours the only symptoms remaining were slight mental confusion and headache, these were gone the following morning. No further attempts at pneumothorax were thought advisable in this case, and thoracoplasty was advised.

CASE 2—A W, a man, aged 24, Jewish, in whom the onset of tuberculosis was thought to have occurred in August 1934 but from the fibrotic nature of the lesion as it appeared roentgenographically it was probably present as an asymptomatic lesion for a considerable time. The lesion was a diffuse, but not very dense, fibrocaceous tuberculosis through the left lung with the largest cavity about 2 cm in diameter. Pneumothorax was started October 6, with a great deal of difficulty in finding a free space. November 3 an attempt at pneumothorax gave

no readings. Before any manipulation or introduction of air was resorted to the patient complained of dizziness and weakness and the needle was withdrawn. He then complained of numbness of the right arm and leg. There was no loss of consciousness or disturbance of respiration or cardiac action. Neurologic examination revealed a right-sided hemiplegia, with right-sided hemianesthesia. There was no involvement of the cranial nerves, Babinski sign, or aphasia. The patient was reassured but no other therapy was used. Complete recovery occurred within one hour. A roentgenogram (which had been taken the day before the accident) showed that the small peripheral collapse previously present could no longer be seen. Several cautious attempts at pneumothorax were made later, but no free pleural space could be found.

CASE 3—M E, a woman, aged 30, Norwegian, in whom the onset of tuberculosis occurred in November 1933, had a fibrocaceous lesion of the right upper lobe with several fibrous cavities. Pneumothorax was attempted on several occasions with six punctures all unsuccessful in finding a free space. Another attempt was made Oct 3, 1934. No free space was found, but during the manipulations bright red blood welled up through the needle when the patient coughed. The needle was at once withdrawn and the patient put to bed. She complained at once of feeling dizzy and after three or four minutes presented marked mental confusion, and disorientation, and had crying spells, and hallucinations. These phenomena subsided in about one hour. The following features made us feel that we were dealing with an organic rather than a functional disturbance: (a) The patient had never shown any evidence of psychiatric symptoms previously. (b) The treatment was painless. (c) She did not realize the significance of our being unable to find a free space. (d) She subsequently underwent a thoracoplasty with no evidence of mental disorder. (e) The symptoms appeared a few minutes after a lung puncture and one that had penetrated a pulmonary vein.

CASE 4—H Z, a woman, aged 28, Jewish, in whom the onset of tuberculosis occurred in 1928 had a pneumothorax on the left side discontinued to enable the start of pneumothorax on the right side in September 1934. Each lung presented partial collapse, pleural adhesions being present. The last refill was given Nov 23, 1934, with no unusual reaction. Her condition remained fair until November 26, at which time, without any previous clinical warning, she suddenly became comatose, exhibiting convulsive seizures, coma and cyanosis. She recovered temporarily and was found to be blind. Before careful ocular study could be made, the blindness gradually disappeared. It was followed within the next few minutes by further convulsions and death. Autopsy was not secured. Clinically this case was one of cerebral accident. In the presence of artificial pneumothorax with adhesions, and severe coughing spells, and in the absence of any cardiovascular disease, of syphilis or of a previous neurologic lesion, and in view of the youth of the patient, we feel that the most likely cause of death was air embolism, in spite of the absence of a recent treatment. The mechanism was possibly a small intrapulmonary rupture, or tear of an adhesion with an alveolovascular communication.

CASE 5—C W, a white woman, aged 22, in whom the onset of tuberculosis occurred in January 1933, had pneumothorax started in April 1933 and continued at weekly intervals to the time of her admission. The patient was admitted to Kings County Hospital April 24, 1934, with a history of having received a refill that morning and of falling unconscious immediately after getting up from the table. On examination the patient was comatose with occasional clonic and tonic convulsions. There was marked spasticity of the entire body, with exaggerated reflexes and a bilateral Babinski sign. Spinal tap taken at this time was negative. The neurologic diagnosis was decerebrate rigidity. A roentgenogram of the chest taken at this time revealed a small basal partial right pneumothorax with the remaining lung showing a fibrocavitary lesion. The patient remained unconscious for from three to four days and then showed signs of a complete left hemiplegia. The paralysis gradually disappeared, complete recovery having been reached at the end of four weeks. The patient was discharged, June 3

⁵ Bingel, Zentralbl. f. Chir. 50: 433 (March 17) 1923. Abstr. J. A. M. A. 80: 1743 (June 9) 1923.
⁶ Gough, J. A. Surg. Gynec. & Obst. 39: 27 (July) 1924.

The following four cases were seen in the private and consulting practice of the senior author

CASE 6—F S, a white woman, aged 22, in whom the onset of tuberculosis occurred in 1929, when seen in July 1931 was emaciated the lungs presented a nodular caseous infiltration of the right upper lobe and cavitation destroying the greater part of the left upper lobe, with caseation to the fourth rib anteriorly. It was felt that the lesion was too extensive and the general condition too poor to resort to pneumothorax at that time. After a period of eight months of bed rest, with marked clinical improvement and fibrotic changes in the lesions, an attempt was made at pneumothorax on the left side. The pleural space was entered without difficulty and seven treatments were given, of 300 cc each. Fluoroscopy showed a small basal pneumothorax. On the eighth treatment the needle entered the pleural space (pressure 0, +2), after 100 cc the pressures were +2, +4. The valve was opened and air was again run in, at this point the patient exclaimed, became in rapid succession pale, unconscious, cyanotic, apneic and pulseless and then died, in spite of the use of artificial respiration and intracardiac epinephrine. Necropsy was not performed. The mechanism in this patient was undoubtedly the partial severance of a vascular adhesion with air forced into the vessel thus exposed.

CASE 7—T L., a white man, aged 35, in whom the onset of tuberculosis occurred in 1930, first seen in July 1931, had a lesion that consisted of a fibrocavitary tuberculosis affecting especially the right upper lobe. Artificial pneumothorax was started in August 1931. The first three treatments of 175, 600 and 600 cc., respectively, were given with little difficulty. On the fourth treatment the pressures were -2, +2, going to -4 with deep inspiration. The manometer was then closed and the air allowed to run in. After about 20 cc. had been given the patient complained of pain in the right leg, he immediately became unconscious, with the development of pallor and then cyanosis, respirations ceased and the pulse became imperceptible. Treatment of artificial respiration and intravenous epinephrine gradually brought about reestablishment of the vital functions. It was then noted that there existed a complete right hemiplegia, at this time (from fifteen to twenty minutes after the accident) the eyegrounds were normal. When consciousness returned the patient was found to have a complete aphasia. These neurologic manifestations all disappeared within the next twenty-four hours. Fluoroscopic examination after recovery showed no pneumothorax, and the conclusion was arrived at that the air must have been injected into the lung during all four treatments, in spite of deceptive manometric oscillations.

CASE 8—E R., a white woman, aged 30, in whom the onset of tuberculosis occurred in 1931, had a left pneumothorax started in 1932 and continued with a partial but apparently satisfactory collapse until May 1934, at which time a spreading lesion was observed on the right. The left lung was allowed to come out and pneumothorax was started on the right. In spite of attempts at a bilateral partial collapse, the left lung became adherent to the periphery and began to reexpand rapidly. August 19 the needle was introduced into the left side of the chest. No readings were obtained. In the midst of the ensuing manipulations, no air was being introduced, the patient cried out and the needle was withdrawn. She became unconscious, very pale, and then cyanotic. The pulse became slow and irregular (from 40 to 50), respirations became slow (from 4 to 5) and irregular and gasping. After a period of from four to five minutes, during which epinephrine and caffeine were used liberally, the patient made a gradual and uneventful recovery. In this case the beveled tip of the needle must have effected a continuous passage between a pulmonary venule and an alveolus.

CASE 9—L. L., a white man, aged 19, in whom the onset of tuberculosis occurred in January 1933, was first seen in January 1934. The lesion consisted of a bilateral upper lobe fibrocavitary tuberculosis. Pneumothorax was attempted on the left side in February 1934. After several unsuccessful attempts, scanty oscillations were obtained (0 -2). As no better fluctuations could be secured a small amount of air (from 5 to 10 cc) was introduced. This was followed immediately by restlessness, vomiting, pallor, cyanosis and profuse perspiration. Consciousness was not lost. When his condition was no longer

critical, paralysis of the right leg was noted. This cleared in from two to three hours, leaving no residuum. In this case the needle must have been at least partially in one of the branches of the pulmonary veins.

COMMENT

Air embolism occurs about once in every 500 to 1,000 pneumothorax treatments.

Pathogenesis—The factors necessary for the production of air embolism of this type are the same as those stated previously. The normal lung is elastic, and the lung and blood vessels tend to be pushed away by the needle rather than to be punctured, and the vessels tend to retract or collapse when punctured. However, when the lung is fibrotic, firm and adherent, with thick, vascular pleural adhesions, collapse becomes much more difficult as does vascular retraction. The second provision—increased air over venous pressure—is normally present. The pressure in the pulmonary veins is normally less than atmospheric, by as much as from 14 to 16 cm of water⁷ and from 5 to 6 cm less than the intrapulmonary pressure, and this difference is markedly accentuated when the air pressure is increased by the use of the pneumothorax machine or by coughing, or when the venous blood pressure is decreased by forced sudden inspiration. The perforated vessel through which the air enters may be in the lung or in a vascular adhesion. Riviere says that such vessels may enlarge to almost angiomatic dimensions. Schlaepfer⁸ attempted to reproduce in dogs the pulmonary conditions of a fibrotic tuberculous process, by artificial vascular obstruction at the hilus and succeeded in the production of vascular adhesions in the pleura, which established anastomoses between the pulmonary and the peripheral venous circuits. Air introduced into such a vessel would then pass through the left side of the heart and thence to the general arterial circulation, as would air introduced into a branch of a pulmonary vein. The air may come from one of four sources: (a) The air may be introduced by the operator from the pneumothorax apparatus, (b) it may be sucked in from the tubing of the manometer, (c) it may be sucked in from an alveolus or bronchiole, the bevel of the needle acting as a connection between the air sac and the blood vessel, or (d) by a similar action it may be sucked or forced in from the pleural space if a partial pneumothorax already exists.

Clinical Features—This syndrome has been amply reproduced in animals⁹ of all sorts,⁹ but in them the features are similar to those in man except that the syndrome can be observed more exactly and dispassionately. The type of case in which air embolism is found, when associated with artificial pneumothorax, is practically always one in which the lung appears more or less fibrotic, and the pleura is, and feels, thickened when perforated. In this group is found the case in which pneumothorax was once given and abandoned, as well as the one in which the lung has been gradually reexpanding owing to an obliterative pleuritis, in spite of continued pneumothorax treatments. If careful roentgen study is not made as the treatments are continued, the latter eventuality may develop with the physician unaware of its occurrence. In these cases, in which as a rule no free space can be found, many punctures are made and often, as well, hazardous attempts at introduction of air in the absence of satis-

factory readings. By far the most frequent occurrence is at the induction of the pneumothorax, and especially the third or fourth attempt when there is no established air space.

Before we pass on to a more detailed description of the syndrome it is desirable to mention the other causes of this type of air embolism. Chest injury is one of the less common causes. Cases of air embolism have resulted from pleural lavage in empyema. Schlapfer¹⁰ studied cases of general reaction following pleural lavage, changing chest drainage tubes and the like and came to the conclusion that most of them were true cases of cerebral and peripheral embolism, finding such pathognomonic signs as blindness, hemiplegia and marbling of the skin. Brandes¹¹ encountered a fatal reaction while injecting bismuth paste into an empyema cavity to outline it. At the autopsy the patient was found to have bismuth in the cerebral vessels, and an open vessel was discovered in the chest cavity. One type of air embolism due to air in the peripheral arteries, not usually considered as air embolism, is caisson disease. In this condition the air is liberated from solution in the blood by a decrease in compressed air pressure. The symptoms are due in 90 per cent of the cases to peripheral air embolism affecting the muscles, in about 10 per cent cerebrospinal involvement is shown by vertigo, paralysis and death. However as already stated, the majority of cases of air embolism are associated with pneumothorax therapy.

Practically always on introduction of the needle the readings are found to be unsatisfactory, resulting in either no fluctuations or those characteristic of intrapulmonary pressures (-2 , $+2$, perhaps going to -4 with deep inspiration or to $+4$ with cough). Occasionally, however, satisfactory readings of not very great negativity may be obtained, as -4 , -2 , becoming even more negative with forced inspiration. In the last type of case, when symptoms of embolism follow the injection of even a small amount of air, the possibility of the negativity being due to an intravascular location of the needle tip must be considered, although the probability is greater that the needle, originally intrapleural, is dislodged by a respiratory movement. The symptoms of embolism may manifest themselves before any air is introduced (on which occasions it comes from an alveolus or the pleura) or after a variable amount has been allowed to run in—anywhere from 10 to 500 cc. Similarly, they may appear when the needle is in place, immediately on its withdrawal or after several minutes.

As a warning sign the patient may cough up a small amount of blood, or blood may well up through the needle or may be found on the tip of a stylet introduced to find the cause for the absence of proper fluctuations. The initial symptoms vary from slight to severe. Often the patient will first complain of local pain, of severe coughing or of feeling "queer." The first sign may be pallor or dizziness, followed by coma and sudden death, a neurologic lesion or mental confusion. Objectively the first sign is often pallor, commonly followed by intense cyanosis. Bradycardia, loss of consciousness, convulsive twitching, cardiac irregularities, apnea or respiratory difficulty, urinary and fecal incontinence and vomiting may occur in the severe cases. Focal neurologic signs may appear at once or not until the elapsing of a variable number of minutes. Any part of the brain may be involved, the commonest of the

easily recognized syndromes is hemiplegia. It is claimed that when the patient lies on the right side the left common carotid will be involved most frequently, and vice versa because of the tendency of the air to float uppermost on the blood stream, but this is not borne out by the statistics. Undoubtedly many other areas of focal embolism occur, but, because of the transient nature, the difficulty of diagnosis and the direction of all efforts toward the desperately ill patient, these are usually overlooked. Areas of skin blanching and marbling as evidences of air embolism are mentioned. In the *Lancet*¹² is reported one case in which two clearly demarcated areas of skin blanching appeared on the left arm evidences of obstruction to two branches of the left brachial artery. The relationship of coronary air embolism to the clinical features and to sudden death is questionable. In animals it has been shown¹³ that injections of intracoronary air are capable of causing death. Air in the retinal arteries has been described¹⁴ as visualized with the ophthalmoscope and may be the explanation for the presence of blindness as one of the symptoms of cerebral air embolism. Since time cannot usually be spared to examine the eye grounds in these cases because of the urgency of the general condition the detailed description of the changes is taken from Wever's⁹ work on monkeys. When only from 1 to 2 cc of air was injected into the carotid, the retina presented first bubbles and then columns of air in the arteries. These could be seen to lengthen and thin out into silvery streaks as the smaller usually invisible arterioles became distended with air. The veins were then seen to be distended, but no air could be seen, the last mentioned was thought to be due to the presence of many microscopic bubbles that had passed through the capillaries. In some cases temporary mental changes—confusion, emotional disturbances and the like—may be the focal signs. In such instances the symptoms must be very carefully evaluated, to rule out the more common "nervous" manifestations that may follow any more or less painful procedure. The further course of the condition varies with the individual case. In some the condition clears very quickly, while in others recovery may take a period of time varying from hours to many days. Occasionally a permanent defect may result.

Prognosis—Air embolism is fatal in percentage varying from 15 to 50. Five of Reyer and Kohl's¹⁴ ten patients died (50 per cent), only two of our nine patients died (22 per cent). On the other hand, the prognosis of the patient who survives the first ten or fifteen minutes after the accident is good, and after one hour has elapsed the danger is very slight, even in the face of persistent coma or paralysis. The prognosis of recovery of the focal neurologic lesions is also good.

Pathology—Some cases have come to autopsy without any definite changes, the air escaping, or perhaps being divided up in the capillaries and arterioles. Other cases show air in the cerebral vessels. In this connection it is well to mention Riviere's¹⁵ warning that air may normally be present in the pial veins. Some pathologists advocate doing the head under water, better to detect the presence of air. The skull should be opened with the greatest of care. Bishop's¹⁶ case,

11 Quoted by Schlapfer¹⁰

showed air in all the vessels of the right side of the brain. Saugman¹¹ also reports such cases. The pathologist must be careful not to mistake air introduced by decomposition, or from without, for air embolism.

Therapy—This feature is logically divided into two parts, prophylaxis and actual therapy. Of these, the former is of much more importance. The following are some of the many suggestions made by various operators:

Air should not be given unless the fluctuations are those of intrapleural pressures, use of a blunt needle, on the initial treatment especially, to lessen the chance of pulmonary or vascular puncture, use of very fine needles with short bevels to lessen the trauma, use of wide-bore needles to make the chance of entering a vessel slighter, use of air under negative pressure to lessen the chance of forcing it into a vessel, use of a very short and thin manometer tubing to lessen the chance of air being sucked out of this tube into a blood vessel, use of a manometer with a tambour instead of a water manometer to lessen the chance of suction of air from the manometer tube, use of specially constructed syringes, use of oxygen or carbon dioxide instead of air, especially for the initial treatment, prevention of coughing and deep breathing during the initial treatment, keeping the patient's head below the rest of the body during the initial treatment, keeping the patient on the table for from ten to fifteen minutes after a treatment, and especially when it is felt that the lung has been punctured, or blood has been seen on the needle or stylet.

The latter two provisions are suggested by Reyer and Kohl, because many patients develop symptoms only when the head is raised as the patient starts to get off the table. This was also found true in dogs¹⁰ which developed cerebral embolism only when the head was elevated. Clinically, however, cases have occurred with great frequency with the needle yet in the chest and the head lower than the chest. J. B. Murphy¹¹ suggested cutting down on the pleura in every case to prevent the development of air embolism. It is difficult to analyze and evaluate most of these devices, as each has some theoretical or actual reason. Most important of the precautions to be followed are as follows: (a) Unless on fluoroscopy or recent roentgenogram the lung is seen to be well away from the chest wall, no air should be given until free characteristic intrapleural oscillations can be secured. (b) The greatest of care must be used on the initial treatment, as well as in those patients in whom difficulty has been experienced. A blunt needle is desirable. The readings should be taken every 5 to 10 cc. for the first 50 cc. at least to preclude the possibility of the needle tip originally intrapleural having penetrated the lung. The needle, when once in the pleural space, should be held firmly to prevent its dislodgment. The slightest untoward movement or sign on the part of the patient should result in the withdrawal of the needle. If a free space is not found at once the operator should be especially on guard for the development of air embolism. Epinephrine should be near at hand. The first treatments should be given, or at least supervised, by one who has a great deal of experience with artificial pneumothorax therapy.

Therapy after cerebral embolism has occurred is symptomatic and may vary from simple reassurance to epinephrine (intravenously or intracardiac if necessary), caffeine, artificial respiration and the like depending on the manifestations in the individual

case. If there are no other contraindications, artificial pneumothorax may later again be resorted to.

Diagnosis and Differential Diagnosis—To the physician who is familiar with the syndrome, the sudden appearance of symptoms during or immediately after a treatment will present little or no diagnostic difficulty. Air embolism bears no resemblance to tuberculous meningitis or tuberculoma. The only question of differentiation arises in the consideration of such functional disturbances as fainting or hysteria, and in the consideration of pleural shock. We might also mention in passing the possibility of the concomitant occurrence of a cerebral vascular accident simulating air embolism, also, when diagnostic or therapeutic pneumothorax is performed for such pulmonary diseases as abscess, bronchiectasis or tumor, a cerebral embolus (not air embolus) might result.

The question of pleural shock deserves separate consideration. Pleural shock (pleural reflex, pleural eclampsia, pleural epilepsy) is a syndrome caused by irritation or puncture of the pleura and is characterized by the appearance of a group of symptoms not unlike those of air embolism. It occurs almost only when the pleura is healthy or only slightly diseased. Forlanini¹¹ believed that all severe reactions were pleural shock, not air embolism. Many cases of so-called pleural shock are vague and ill defined and are much more accurately interpreted as fainting spells, as the effect of extreme nervousness as an excessive reaction to pain, and in cases in which there appear focal neurologic signs, as air embolism. Wever⁹ showed that small amounts of air injected into the carotids of dogs produced the symptoms of "pleural shock," while larger doses produced true air embolism. We have already seen the mechanism whereby air embolism may occur without the injection of air, and it has been demonstrated¹¹ that cerebral embolus may complicate pleural lavage. There are, however, apparently authenticated cases of pleural shock in which the syndrome was repeated on each successive puncture of the pleura.⁷ This would certainly seem extremely improbable if air embolism were the cause. Symptoms may appear while the pleura is being punctured or while the needle is being withdrawn. The attacks, if recurrent, often tend to become worse with each successive puncture. Any case presenting focal neurologic signs or evidence of embolism elsewhere (air in the retinal vessels or focal blanching of the skin) is certainly air embolism. Similarly, if the phenomenon occurs immediately on the injection of air, or when the needle is stationary, or when the pleura is known to be badly diseased and thickened, or when evidence of vascular puncture is secured by immediate hemoptysis, or when blood is welling up through the needle or is found on the end of the needle or stylet, air embolism is far more probable. In some cases the differentiation is impossible. The indicated therapy is the same in the two cases. If pleural shock is definitely diagnosed and recurs even once, such a patient should not receive further attempts at pneumothorax.

SUMMARY

Air embolism is a definite, diagnosable, clinical entity. It is logically divided into two groups, one in which air enters one of the peripheral veins and the other in which air enters the pulmonary circuit. In the first group symptoms arise from the presence of air in the right side of the heart and in the second from the presence of air in the cerebral vessels.

INFECTION OF THE URINARY
TRACT IN DIABETESTHOMAS P. SHARKEY, MD
DAYTON, OHIOAND
HOWARD I. ROOT, MD
BOSTON

The inherent susceptibility of the diabetic patient to infection is not only manifested by the frequency with which skin infections are found but further exemplified in the high incidence and serious character of infection of the urinary tract. Almost one in every five diabetic patients coming to autopsy at the New England Deaconess Hospital since 1919 has shown some infectious process in the urinary tract. In 196, purulent infection of the urinary tract was present in thirty-five, or 18 per cent. All other types of nephritis and specific infections have been excluded. This high incidence is not confined to autopsy material, for such infections are frequently found in ward patients.

The tables show the distribution of infection of the urinary tract in the thirty-five patients who came to postmortem examination. In this series there were twenty females and fifteen males. The proportion of females to males in the entire 196 cases is approximately the same, and the proportionate incidence of urinary tract infection is about equal for the two sexes.

The average age at death was 58.3 years. The youngest patient was a youth aged 19, admitted to the hospital in acidosis with right paranephric abscess, which ruptured through the diaphragm into the right thoracic cavity. The oldest patient was a woman, aged 77, admitted with occlusion of the femoral artery and left pyelitis. While some of the most extensive infections occurred in younger individuals, the incidence of infections of the urinary tract was greatest in persons past middle life.

The average duration of diabetes for the entire group was 9.7 years, owing to the inclusion of several cases of extremely long duration. The striking feature was the presence of severe kidney or bladder infection in cases with a relatively short duration of diabetes, seventeen of the thirty-five patients had diabetes for less than five years, and ten had diabetes less than three years. The increased susceptibility to infection in the diabetic patient must originate soon after the onset of the disease, as is demonstrated not only in this group but also in those patients in whom the onset of diabetes is soon followed by skin infections.

Infection of the urinary tract in the autopsy series fell into three main etiologic groups: (1) hematogenous, (2) ascending and (3) unknown.

Group 1 provided by far the largest number of patients, including twenty-six cases, or an incidence of 74 per cent of the thirty-five cases. This is undoubtedly accounted for in part by the presence of severe infections with virulent organisms, especially staphylococci and streptococci. It seems apparent that an analysis of ward patients would reveal a higher incidence of ascending urinary infections with *Bacillus coli*.

A wide variety of associated infections is seen in table 1, in which the term "skin infection" is used to include furuncles, carbuncles, subcutaneous abscesses and infections associated with peripheral gangrene.

Eighteen of the cases fall into this class (3, 4, 5, 6, 7, 8, 9, 10, 11, 13, 16, 18, 19, 21, 22, 24, 21b and 25). Staphylococci and streptococci were the most frequent bacterial species found in the skin infections, the former predominating. In this group hematogenous dissemination of bacteria to the kidneys was the usual mechanism of infection. Staphylococci were demonstrated in the blood in ten cases before death (3, 4, 5, 8, 13, 16, 21, 19, 22 and 9). Streptococci were demonstrated in the blood in one case before death (6), and pathologic changes consistent with streptococcal septicemia were found in another (25). Death was ascribed to sepsis in two other cases in this group, and, although laboratory confirmation was lacking, bacteremia was probably present (cases 11 and 16).

Other infections in group 1 include appendical abscess, two cases (1 and 14), primary pneumonia, two cases (2 and 23), bronchiectatic abscesses, one case (12), prostatic abscess, one case (15), otitis media, one case (17), and periurethral abscess, one case (20). In this group of cases streptococci were demonstrated in the blood in one case (23) and staphylococci in one case (15). Postmortem evidence of septicemia was observed in one case (14). Ten of the twenty cases with renal infection showed gross renal abscesses, an incidence consistent with the nature of the invading organisms.

Five cases of cystitis without renal infection occurred in this group, four of which were associated with chronic infections elsewhere (16, 17, 18 and 25) and one with a subacute process (1). No obstructive or static cause for the cystitis was demonstrated at autopsy. One patient died from metastatic abscesses from a gangrenous leg, another from toxemia secondary to a gangrenous leg, another from septicemia secondary to a gangrenous leg, another from pneumococcal meningitis and another from generalized peritonitis. Several of the latter cases might have been included in the "unknown etiologic group," but they were included in group 1 since peripheral infection was definitely present and evidence of toxemia or septicemia existed in the majority.

Ascending urinary tract infection was not commonly observed in the autopsies, as is seen in table 2. The majority at autopsy showed no obstructive lesion in the urinary tract. In three cases the obstruction was due to calculi, in one to urethral stricture and in one to prostatic hypertrophy. Two of the patients with calculi had typical ureteral colic and one passed "gravel." Only one case in the entire series showed urinary tract infection secondary to prostatic enlargement. Considering the fact that the average age at death for the males in the autopsy series was over 60 years, this seems unusual. However, among hospitalized diabetic patients, infection of the urinary tract secondary to prostatic obstruction is relatively rare.

An analysis of ward patients reveals a higher incidence of *Bacillus coli* infection, following obstructive lesions, catheterizations, and conditions producing stasis in the bladder, in the latter instance cystoceles in female patients constitute a not generally recognized reservoir of infection.

In three cases of pyelitis without pathologic evidence of parenchymal renal infiltration, cystitis was absent in two (6 and 11). All these cases were associated with infection elsewhere in the body, one with gangrene of the lower extremity, one with bronchiectatic abscesses, and one with a carbuncle, the last patient died of

staphylococcic septicemia Hematogenous implantation of bacteria was the most likely source for the renal infection

Group 3 constitutes the most baffling one in the series in that no known etiologic factor could be demonstrated at autopsy This group makes up a considerable portion of hospitalized cases and gives the clinician and urologist no end of concern in that there is no surety in the frequently mild and usually symptomless cases that invasion and destruction of the renal parenchyma is not taking place

Five such cases are represented in table 3 (31, 32, 33, 34 and 35) In four of these cases renal infection was the immediate cause of death (31, 33, 34 and 35) and possibly in the other case provided an indirect cause of death Two of these cases showed evidence of septicemia at autopsy secondary to the renal infection (34 and 35) No symptoms pointing to renal infection were present in any of these cases except one in which pain in the side was noted two weeks before hospital admission Two of these cases were admitted to the hospital with unexplained fever and each subsequently showed local kidney tenderness to bimanual palpation

A small but interesting group of patients constitute a clinical entity not yet confirmed by pathologic study

These patients have unexplained paralysis of the bladder usually associated with absence or diminution of patellar and achilles tendon reflexes, disturbances in peripheral sensation and sometimes peripheral polyneuritis Motor weakness and trophic lesions are uncommon Those cases associated with motor weakness have frequently been described as *tabes peripherica diabetica* and *pseudotabes diabetica* The coexistence of arteriosclerosis in such cases is common Degenera-

tive changes, probably on an arteriosclerotic basis, have been found by Warren in the spinal cords of some diabetic patients One such case with unexplained bladder paralysis and urinary tract infection came to autopsy but the spinal cord showed no degenerative changes, however, extreme generalized arteriosclerosis was found

Woltman and Wilder¹ reviewed forty-two cases in which neuropathologic changes were described in diabetic patients, in twenty-eight of which the spinal

cord was examined They do not believe that the degenerative cord changes were of the type found in pernicious anemia as described by Sandmeyer,² Leyden and Goldscheider³ and Naunyn⁴ The same authors presented ten cases of diabetic neuritis, with post-mortem neuropathologic studies in three cases The degenerative changes noted in the three spinal cords were slight, and most of it could be explained on a basis of senility and arteriosclerosis They believe that the lateral columns are seldom, if ever involved in diabetes and that the mechanism of the production of the lesions reported as occurring in the posterior columns must be different from those which occur in pernicious anemia The recent literature on neuropathologic changes observed in diabetes is scant, especially as regards degenerative cord changes Until more of these cases have been studied at autopsy, the etiology of this type of bladder paralysis will remain obscure

In table 4 are listed three patients admitted in diabetic coma and four in acidosis In three of these cases urinary tract infection was of a relatively acute type (2, 5 and 32) On the first admission of case 35, in acidosis, white blood cells appeared in the urine, and in two months death had occurred from septicemia secondary to multiple renal abscesses Septicemia occurred in two other cases (5 and 21) and active urinary tract infection was present in all of these coma cases

COMMENT

The frequency of urinary tract infection in diabetes not only is demonstrated in an analysis of 196 autopsies on diabetic patients since 1919 but is found to be of common occurrence in hospitalized patients The nature of the disease and the inherent susceptibility of the tissues to infection in the diabetic patient make him an easy prey to urinary tract infection

Infection of the urinary tract is most apt to occur in the uncontrolled or inadequately controlled case of diabetes This is particularly true when the urinary tract infection was secondary to infection elsewhere in

the body, especially in cases of skin infection in the uncontrolled case of diabetes with subsequent development of bacteremia. As an example, case 24 might be cited, a woman aged 24, with uncontrolled diabetes of ten years' duration developed skin and subcutaneous abscesses, which led to severe bilateral pyelonephritis and terminal meningitis. That this is not an infallible rule, however, is seen in hospital patients who developed ascending urinary tract infections in the presence of urinary stasis even when the diabetes has been under fairly good control.

The paucity of symptoms in these autopsies and in those admitted to the hospital wards, even with severe and extensive urinary tract infection, is striking. Some of our most severe cases have presented a noticeable absence of symptoms referable to the urinary tract. Patient 35 was admitted recently to the hospital with the symptoms and signs of encephalitis. No symptoms were present that suggested urinary tract infection, and the presence of a few leukocytes in the uncatheterized urine was regarded as of no significance. On readmission two months later the left kidney was enlarged and tender, and marked pyuria was found. Septicopyemia developed and the patient died. Autopsy revealed severe bilateral pyelonephritis with multiple renal abscesses and marked purulent cystitis.

Ketonuria has been shown by Rector and Wheeler⁵ to have a most striking sedative action on the bladder mucosa, despite the fact that the urine shows as many bacteria and pus cells as before ketosis developed. The relative absence of symptoms in our diabetic patients with urinary tract infection and acidosis may possibly be explained on this basis, since many of our patients are admitted to the hospital with both conditions. However, the absence of symptoms is not thus explained in the group without acidosis. Here the diabetes itself may be the primary factor, especially since it is known that sensory disturbance, even anesthesia, is not uncommon in every case at least once a week. Repeated microscopic examinations of the urine of patients with unexplained fever has frequently led to an early diagnosis of urinary tract infections.

marked and the presence in the urine of a large quantity of sugar is accepted as the cause for the frequency of urination, dysuria, nocturia and local irritation. It is important to emphasize that the analysis of the diabetic urine is not complete without microscopic examination of the sediment.

It is the practice in the New England Deaconess Hospital to have a complete examination of the urine

TABLE 4—Cases of Diabetic Coma and Renal Infection and of Acidosis Without Actual Coma

31	♂	19			Paranephritic abscess

made in every case at least once a week. Repeated microscopic examinations of the urine of patients with unexplained fever has frequently led to an early diagnosis of urinary tract infections.

Physical examination is commonly negative in these cases, but, when renal infection has occurred, kidney enlargement may sometimes be discovered. Local tenderness over the renal areas is often present on bimanual examination. Fever with or without kidney enlargement, but accompanied by local kidney tenderness on bimanual examination even in the absence of symptoms, should direct attention to the urinary tract. The chronicity of urinary tract infection with the tendency to acute exacerbations is an unfortunate feature of the disease in some cases of diabetes. In the autopsy series, pus was known to be continuously present in the urine in one case during a period of eighteen years. This is likewise seen in the clinical cases when the patient survived sepsis secondary to infection elsewhere in the body, only to be left with chronic debilitating renal infection (two cases) which, if it does not eventually directly lead to death, indirectly predisposes the patient to death by increasing his susceptibility to other types of infection.

With the increased susceptibility of the diabetic patient to infection, one is constantly in a quandary as to whether one should catheterize the patient and if so, when. In cases of an emergency nature, such as acute retention, there may be no alternative. When possible, we have refrained from catheterizing our patients for fear of urinary tract infection. Following operations or conditions associated with inability of the patient to void, we have endeavored whenever possible to control the insulin dosage by frequent micro blood sugar determinations until the patient is able to void voluntarily. When catheterization is not of an emergency nature and is done solely for diagnostic purposes, it has been our practice to administer sodium acid phosphate and methenamine for forty-eight hours before and at least forty-eight hours after catheterization. In the treatment of diabetic coma, catheterization is avoided if possible. Sometimes it is necessary and in those cases a retention catheter is preferred to frequent catheterizations.

TABLE 3—Infections of the Urinary Tract with Unknown Etiology

Case	Sex	Age	Duration of Diabetes Years	Pathologic Lesions
31	♂	19	0.9	Right paranephritic abscess rupture into thoracic cavity

mon in the patient with diabetes. This is particularly realized when one sees minor surgery being done without anesthesia on the feet of some diabetic patients. First and second degree burns of the skin from local application of excessive heat, and gangrene, occurring from baking the feet in an oven at a sufficient temperature to produce destruction of the skin, are not infrequently observed. Unexplained fever in our diabetic patients has led to the discovery of "silent urinary tract infections" by repeated microscopic examinations of the urine.

When mild symptoms referable to the urinary tract are present in the diabetic patient they may frequently be mistaken for those of diabetes per se by the patient and the physician. Not uncommonly, during periods of urinary tract infection, hyperglycemia becomes more

⁵ Rector J. M. and Wheeler, W. E. The Use of the Ketogenic Diet in Chronic Pyuria. New England J. Med. 211: 143-147 (July 26) 1934

The management of urinary tract infection in the diabetic patient should be directed toward general and local treatment. The most important factor under general treatment is the control of the diabetes. The influence of uncontrolled diabetes on infection and of infection on diabetes is too well known to merit further discussion. The source of infection should be eliminated if possible. Incision and adequate drainage of furuncles, abscesses and carbuncles at the optimal time is of the greatest possible importance. Proper surgical care of the septic foot is required. In spite of all precautions, invasion of the blood stream may occur and hematogenous dissemination to the kidneys may result. The not infrequent admission of emergency surgical cases of long duration, in which operation has not been done because of diabetes, is often inexcusable. The treatment of anemia or any other concomitant factor that tends to lower bodily resistance is likewise important.

Local treatment usually requires the cooperation of a skilled urologist. With the aid of Dr. Harvard Crabtree these patients are usually given a trial with sodium acid phosphate and methenamine and sometimes with phenylazo-2-6-diamino-pyridine monohydrochloride, fluids are forced and the patient is observed. In pyelitis and pyelonephritis, when improvement is not manifested in a few days drainage and irrigation is performed by retrograde catheterization. Catheterization is avoided whenever possible. Surgery for perirenal abscess when indicated, has been done. The tendency for abscess to occur in the kidneys of diabetic patients with staphylococci and streptococcal infections has been noted in the autopsy series. Only rarely however, is there an indication for surgery, since the lesions are usually bilateral. Bladder irrigations are performed in cases of protracted cystitis and in some cases of acute hemorrhagic cystitis. Response to treatment in the majority of these cases is slow. Frequent microscopic examination and culture of the urine are the best criteria to determine the extent of the infection and the adequacy and duration of treatment.

Since the recent discovery by Helmholtz⁶ that ketonuria exerts a bacteriostatic or bactericidal effect on certain types of bacteria, especially *B. coli*, there has been an increasing number of cases reported of the treatment of urinary tract infection by ketonuria, especially in England and the United States. Fuller⁷ attributes this bacteriostatic or bactericidal effect of ketonuric urine to the presence of beta-oxybutyric acid, which ordinarily constitutes from 70 to 75 per cent of the ketone bodies, he showed that this effect increased in proportion to the acidity of the urine. This form of treatment is particularly efficient in infections due to *B. coli*. Acidification of the urine to the same p_H values does not produce the same bactericidal effect. The average reaction of the urine of a patient on a mixed diet is between p_H 6.0 and 7.0. According to Schohl and Janney,⁸ optimal growth of *B. coli* occurs at these values, but they are inhibited from growing in the urine at a p_H of from 4.6 to 5.0 on the acid side and from 9.2 to 9.6 on the alkaline side. According to Band and his associates,⁹ a p_H of 4.8 can sometimes be reached

in the urine in a ketogenic diet, at which point the growth of *B. coli* is stopped. Rector and Wheeler⁵ advocate the restriction of the fluid intake in the patient on this regimen.

The production of ketosis in the treatment of urinary tract infection is a distinct advancement in the therapy of this condition. We have not found in the literature reports of any diabetic cases in which this treatment was undertaken. The inadequacy of present-day therapy in this type of infection might justify its use in selected cases. The concurrence of urinary tract infection with acidosis and coma in some of our cases may be due to the nature of the invading organism and to increased tissue susceptibility to infection in the diabetic patient. How much ketosis would offset the latter factor could be determined only by actual trial. We have not seen many reports on the carbon dioxide combining power of the blood in these cases, but it would be advisable to follow this closely in the diabetic case. Strict hospital observation would be required in this form of therapy for diabetes. In diabetic patients the presence of infection and restriction of fluid intake may act unfavorably on the major disease.

The clinical and autopsy data of two illustrative cases are cited.

CASE 35—A woman, aged 65, who had had diabetes for 18 1/2 years, was admitted to the hospital early in February 1934, after neglected treatment for ten years, with low-grade fever, acidosis and symptoms suggestive of encephalitis. On admission the blood sugar was 0.46 per cent, plasma carbon dioxide combining power, 36 volumes per cent, and nonprotein nitrogen 45 mg, only a few white cells were found in the urine. The spinal fluid Wassermann and colloidal gold reactions were negative. In the middle of February the urine showed a considerable number of white cells, but this was not considered to be a cause of her symptoms. During this time no symptoms referable to the urinary tract were present. The average diet was carbohydrate 100 Gm, protein, 30 Gm. and fat, 50 Gm. relatively low figures because of the condition of the patient. The insulin dosage varied from 30 to 50 units daily. She was dismissed from the hospital the latter part of February, presumably improved.

She was readmitted in April with an abscess of the left thigh, which was incised and drained. The urine contained large numbers of white blood cells, and the left kidney was large and tender on palpation. The nonprotein nitrogen had risen to 99 mg per hundred cubic centimeters. Retrograde catheterization revealed pus in both kidneys more marked in the left. She continued to pursue a downhill course despite all treatment and a metastatic infection of the left eye developed. Clinical and laboratory examinations suggested a large abscess of the left kidney and she was operated on in May. Death occurred within twenty-four hours following the operation. The nonprotein nitrogen at the time of death was 57 mg per hundred cubic centimeters.

Autopsy revealed evidence of septicemia with extensive purulent bilateral pyelonephritis with multiple renal abscesses and purulent cystitis. The abscess in the left kidney, drained at the time of operation measured 3 cm in diameter.

CASE 24—A white woman, aged 25, with a duration of diabetes of 11 1/2 years, had been in diabetic coma twice and acidosis eight times owing to neglect on her part. She had been admitted to the hospital five times for incision and drainage of abscesses. Many white blood cells were seen in the urine in April and May 1929, but no symptoms were present referable to the urinary tract. She was readmitted in June 1933, with a perirenal abscess. Physical examination revealed tenderness over both kidneys. The urine showed many white blood cells. She had repeated chills and high fever.

Retrograde catheterization was done which revealed bilateral pyelonephritis. The patient was in the hospital from June to December 1933 during which time she was treated for the urinary tract infection. Repeated blood transfusions were

9 Band, B., Dunlop, D. M., and Dick, I. L. Chronic Pyelocystitis with Particular Reference to the Ketogenic Diet Treatment. Proc. Roy. Soc. Med. 26: 217 (Jan.) 1933.

necessary in an effort to combat constant severe secondary anemia. The patient was expected to die of septicemia during this course in the hospital. In December 1933 she was improved and was dismissed from the hospital.

She was readmitted to the hospital in January 1934 with bilateral otitis media which seemed to respond well to paracentesis. In February a perianal abscess developed which required incision and drainage. She was dismissed from the hospital in February and returned again in March with mastoiditis. Meningitis developed and she died.

Autopsy revealed that the immediate cause of death was pneumococcal meningitis. The kidneys showed bilateral pyelonephritis with evidence of extensive repair and diffuse renal amyloidosis. Purulent cystitis was also present. The prolonged renal infection was undoubtedly the indirect cause of death leading to lowered resistance and increased susceptibility to infection.

These two cases taught us a great deal. Both patients were women, at the opposite ends of life. Both had diabetes of long duration and each neglected her treatment for long periods. Neither was admitted for urinary tract infection and in the first case the diagnosis was missed on the initial admission. Symptoms that would attract attention to the urinary tract were absent in each. Etiologic factors in the first case were not known. In the second, renal infection very likely occurred secondary to multiple peripheral abscesses. The course of the disease in the first was rapid, in the latter case slow. An increased number of white cells in the urine having been noted four years prior to her admission in June 1933. Treatment consisted of forcing of fluid acidification of the urine, use of urinary antiseptics, retrograde catheterization with irrigations and frequent blood transfusions. In the first case treatment was of no avail. In the second, while extensive renal repair was seen at autopsy and constant treatment was carried out under hospital supervision for seven months, the patient succumbed to an intercurrent infection.

SUMMARY

In a clinical and pathologic study of the incidence of urinary tract infection in 196 diabetic cases, 18 per cent revealed at autopsy evidence of urinary tract infection, which could be divided into three main groups: hematogenous, ascending and unknown. Seventy per cent of the cases fell into the hematogenous group, in which infection of the urinary tract was secondary to infection elsewhere in the body. Ascending infection was secondary to obstructive lesions in the urinary tract. In a small group of patients in whom severe renal infection was present, it was impossible to ascertain the etiologic factors.

CONCLUSIONS

1. Urinary tract infection commonly occurs as a complication of diabetes. This is especially true in cases of uncontrolled or inadequately controlled diabetes.
2. Symptoms referable to the urinary tract are frequently absent in these cases.
3. Catheterization is sometimes responsible for the development of urinary tract infection.
4. The tendency of the urinary tract infections in diabetic patients to recurrence and chronicity is common.
5. The occurrence of unexplained fever in diabetic patients should prompt an investigation of the possibility of urinary tract infection.

ILEUS ASSOCIATED WITH TRANSIENT RENAL INSUFFICIENCY

A TRUE ENTERORENAL SYNDROME

E. G. WAKEFIELD, MD
CHARLES W. MAYO, MD
AND
J. ARNOLD BARGEN, MD
ROCHESTER, MINN.

We have observed a group of elderly patients who had signs and symptoms of obstruction of the colon, which were accompanied by an elevation of the blood urea and a decreased urinary output. The onset of the signs and symptoms of obstruction of the lower part of the intestine in these cases was sudden enough to make it urgent to decide whether or not surgical treatment should be advised. We are reporting the pertinent facts in the history, examination, laboratory data and progress in ten such cases, followed by a discussion of the data relating to diagnosis, etiology and treatment.

REPORT OF CASES

CASE 1—A man aged 54, was admitted directly to the hospital on account of abdominal distention, dyspnea and discomfort. Ten years prior to his admission to the hospital he had been operated on for disease of the gallbladder. Following the operation, a postoperative hernia had developed. However, since the operation on the gallbladder he had had attacks of abdominal distention and discomfort which would last for a few hours and would disappear after he had taken a cathartic and an enema. During the past three weeks these remedial measures had failed and the distention and abdominal discomfort had persisted.

On general examination he was found to be well developed and somewhat overweight. The temperature was 101 F. The skin and tongue were dry in appearance. The heart was enlarged and there was a regular rate and rhythm to the heart sounds. The lungs contained musical rales throughout. There was a moderate degree of arteriosclerosis. The abdomen was rather distended and tender. There were no palpable masses. The rectal examination did not reveal anything abnormal.

To avoid repetition, the blood pressures, blood chemistry and urinalysis of this case, as well as those which follow, are given in the accompanying table.

Hot stupes were applied to the abdomen, 3,000 cc or more of fluids was administered by mouth and, if necessary, these measures were supplemented by intravenous injections and warm rectal irrigations with physiologic solution of sodium chloride. During the first two days the urinary output was less than 500 cc daily. However at the end of five days the urinary output was within normal limits, the blood urea had dropped from 88 to 28 mg per hundred cubic centimeters of whole blood, and daily bowel movements had been established.

CASE 2—A man, aged 56, had generally been healthy except for an attack of abdominal pain and distention two years prior to his admission to the hospital. At the time of this attack the abdomen had been explored surgically and only "adhesions" had been found. The convalescence had been normal and he had had no further trouble until three days before his admission to the hospital after he registered at the clinic. Four days before his admission he had had stools that had been watery and explosive in character. The next day the abdomen had become distended and he had had colicky pains in the abdomen, which had become worse. Two days after onset of the present illness, enemas had failed to effect a bowel movement or the passage of flatus. However, just before his admission to the hospital he had passed a small amount of flatus.

Physical examination disclosed that the patient was well developed and well nourished. There was no fever. The abdomen was moderately distended and no masses could be

From the Division of Medicine (Drs. Wakefield and Borgen) and the Division of Surgery (Dr. Mayo) the Mayo Clinic.

palpated Rectal examination did not disclose anything unusual There was a moderate degree of arteriosclerosis

Hot abdominal stupes were applied continuously The fluid intake was kept at 3,000 cc or more, and a 10 per cent solution of dextrose in physiologic solution of sodium chloride was administered intravenously when necessary Warm rectal irrigations were given twice daily At the end of five days of such treatment, the blood urea had dropped from 52 to 36 mg per hundred cubic centimeters of whole blood Roentgenologic studies of the gastro intestinal tract did not disclose anything abnormal

CASE 3—A priest, aged 58, was admitted directly to the hospital He had had good health until two years before, when he had had an acute attack of appendicitis Appendectomy had been performed and he had made an uneventful recovery He had been well for ten months and then he had begun to have continuous pain in the upper part of the abdomen He was not certain but thought this abdominal pain had been made worse by exercise Occasionally he had had some nausea and vomiting These difficulties had cleared up so that during the six months prior to the present illness he had not had any discomfort One week before his admission to the hospital he had begun to have abdominal distention He had taken a mild purgative, which had been ineffective The following day he had taken an enema, which had returned clear After he had taken the enema, the abdomen had become more distended

best heard in the mitral area A moderate degree of arteriosclerosis was present The abdomen was greatly distended but there were no palpable masses An exploratory laparotomy was performed and no evidence of obstruction was found The lower part of the ileum and first part of the colon were dilated

CASE 5—A man, aged 65, had had good health until about a year before, when he had begun to have a "dragging" pain in the left lower quadrant of the abdomen and difficulty in obtaining a daily bowel movement It had been necessary to resort to purgatives, and continuously increasing dosage had been necessary to get results During the past eight weeks he had had intermittent attacks of abdominal distention and discomfort Each successive attack had become more severe until the distention and discomfort had been present constantly

Physical examination revealed that the patient was large and had a rounded, distended abdomen There was definite tenderness of the abdomen, but no masses were discovered The tongue was dry and coated and there was a foul odor to the breath Examination of the eyes revealed arcus senilis There was no fever There was a moderate degree of arteriosclerosis The heart and lungs were within normal limits The rectum contained hard, fecal material, which was broken up and removed digitally Roentgenologic studies of the gastro intestinal tract did not disclose anything abnormal

Hot abdominal stupes were applied, warm rectal irrigations were given and the fluid intake was maintained at 3,000 or

On general examination the patient was found to be well developed and healthy appearing The pupils reacted to light and in accommodation The tongue was dry and the thyroid gland was not enlarged He did not have any fever The heart and lungs were normal The abdomen was moderately distended but there were no palpable masses Rectal examination revealed nothing unusual There was a moderate degree of arteriosclerosis

Exploratory laparotomy was performed immediately but no obstruction was found There was considerable dilatation of the ascending and transverse colon The gallbladder was filled with stones and was removed

The patient was seen six years later and had been well until recently, when a frank renal insufficiency had developed

CASE 4—A man, aged 61, had had good health until two weeks before the onset of the present illness, when he had had a mild attack of abdominal distention, which had lasted only an hour or two and which had not been followed by any apparent sequelae On the day before his admission to the hospital he had eaten a light breakfast and had had a normal bowel movement About one hour later he had begun to belch and the abdomen had become distended and had caused discomfort The discomfort soon had become generalized and had been accompanied by crampy pains The abdominal distention had increased and had been accompanied by vomiting The family physician had given enemas without producing the desired results The abdomen had become more distended

On general examination he was found to be obese and he appeared rather ill and drowsy The drowsiness was apparently the result of a hypodermic injection of morphine There was no fever The heart rate was about 100 beats per minute however, the pulse was regular and of good quality The heart was somewhat enlarged, there was a systolic murmur which was

more cubic centimeters daily During the first three days the urinary output was below 1,000 cc for each twenty-four hours Seven days after his admission to the hospital, the blood urea had fallen from 71 to 26 mg per hundred cubic centimeters of whole blood Five months later he apparently was in good health

CASE 6—A man, aged 73, who had abdominal pain and distention, hiccup and anuria, was admitted directly to the hospital, Aug 1 1934 In the past he had had good health June 29, 1934, he had submitted to repair of bilateral inguinal hernia He had received a daily enema for the first ten days after operation, and since this time he had been unable to secure an adequate bowel movement without the aid of an enema Since July 28 he had been unable to obtain any fecal material with the enemas July 29 the abdomen had been "bloated," and following the evening meal there had been cramps in the lower part of the abdomen, and occasional vomiting By the following day the abdominal pain and distention and the vomiting had increased considerably and he had been unable to void urine The physician had been unable to obtain urine with a metal catheter or to obtain flatus or feces with an enema, which had been supervised personally Cramps in the legs were at times rather pronounced

The patient was well developed and did not have any fever The pulse rate was 108 beats per minute There was a moderate degree of arteriosclerosis The systolic blood pressure was 105 mm of mercury and the diastolic blood pressure 80 mm There was hiccuping and the abdomen was distended and tender, but there were no masses in the abdomen Examination of the rectum did not reveal anything abnormal

Hot abdominal stupes were applied warm saline irrigations given and the fluids kept to 3,000 cc daily A diet low in residue was given Ten days after his admission to the hos

pital, the urinary output had increased from less than 800 cc daily to 2500 cc in each twenty-four hours. The blood urea had dropped from 60 to 30 mg per hundred cubic centimeters of whole blood. Roentgenologic studies of the gastro intestinal tract did not reveal anything abnormal. Six months later he was in good general health.

CASE 7—A man aged 66, had been in good health until one year before examination when he had had some "gras on the stomach." For six months he had had colicky pains in the region of the umbilicus and he had felt that cathartics were necessary. For five months there had been daily distress in the lower part of the abdomen. The appetite had been poor and he had lost weight. In spite of daily cathartics, the constipation had become more obstinate.

The patient was poorly nourished. He did not have any fever. The pupils reacted to light and in accommodation. The heart was not enlarged and the cardiac sounds were normal.

The usual regimen of hot abdominal stupes, warm rectal irrigations with physiologic solution of sodium chloride and the maintenance of the fluid intake at 3000 cc or more for each twenty-four hours was instituted. The urinary output rose from less than 1000 cc daily to 1500 cc or more in each twenty-four hours. A diet that was low in residue was prescribed and in twelve days the value for the urea was 40 mg per hundred cubic centimeters of whole blood, whereas on admission there had been 126 mg of urea per hundred cubic centimeters of whole blood. Roentgenologic studies of the gastro-intestinal tract did not reveal anything abnormal.

CASE 8—A woman, aged 72, was admitted to the hospital seriously ill. One week prior to her admission to the hospital she had had pain in the lower part of the abdomen and distention, which had been followed two days later by nausea and occasional vomiting. Three days after onset of the present illness, the vomiting had become so severe that it probably was stercoraceous. After one day the vomiting had ceased and since then she had had severe hiccups. During the first five days of the illness she had not had a bowel movement and, so far as the family knew, she had not passed any flatus. Her general health before the present illness had been moderately good, with the exception of slight loss of weight and occasional headaches.

General examination revealed that the patient was rather frail. There was no fever, but the pulse rate was 120 per minute. The pupils reacted, the tongue was dry and rough and the heart and lungs were essentially normal. There was an arteriosclerosis of moderate degree. The abdomen was greatly distended and tender but there were no masses in the abdomen. Rectal and pelvic examinations did not reveal anything abnormal. The reflexes were equal and there was no edema.

Hot abdominal stupes and warm rectal irrigations relieved the distention in a few days. The patient appeared to be improved. However, after a few days the urinary output decreased, the blood urea rose to 220 mg per hundred cubic centimeters of whole blood, and nine days after her admission to the hospital she died.

CASE 9—A man, aged 82 had been in good health until two days prior to his admission, when he had had nausea which had been followed by vomiting and colicky abdominal pains. For years he had had constipation and had not had a bowel movement without the use of purgatives. For two days prior to the onset of the present illness he had not had a bowel movement and enemas had been of no avail. His appetite had been good but he had lost 20 pounds (9 Kg) during the past year.

He was generally well developed but poorly nourished. There was no fever, the pulse rate was 100 beats per minute, the systolic blood pressure was 225 mm of mercury and the diastolic 130 mm. There was a rather marked arteriosclerosis. The pupils reacted sluggishly to light. The lungs were clear. The heart was somewhat enlarged but there were no significant murmurs. The abdomen was distended but without palpable masses or localized tenderness. Rectal examination did not reveal anything abnormal. The reflexes were equal and there was no edema.

Continuous hot abdominal stupes, rectal irrigations maintenance of the fluid intake at 3000 cc or more daily, and the

low residue diet quickly relieved the abdominal symptoms. The blood urea dropped from 62 to 40 mg per hundred cubic centimeters of whole blood. However, the patient died suddenly on the third day after his admission to the hospital, probably as a result of coronary heart disease. Necropsy was not obtained.

CASE 10—A man aged 84, was admitted directly to the hospital. For twenty-five years he had occasionally resorted to a catheter for the relief of a urinary obstruction. After a few days of catheterization he usually had been able to void again. Following self catheterization one month before, the left testicle had become swollen.

He had had regular bowel habits until three days prior to his admission to the hospital, when the abdomen had become distended and had caused discomfort. He had taken an enema without results. The following day he had taken repeated enemas and a dose of castor oil, which had produced nausea, vomiting, hiccups and more marked abdominal distention.

He was generally well developed and well nourished. The skin and mucous membranes were of good color. The pupils were small probably as a result of a dose of morphine. The temperature was normal. The heart and lungs were essentially normal. The abdomen was greatly distended and tender, but no masses could be palpated. There was a moderate ventral hernia but there were no incarcerated loops of intestine. There also were moderately large inguinal hernias which were well supported by trusses. The rectal examination revealed prostatic hypertrophy.

Hot abdominal stupes, warm rectal irrigations and a low residue diet were administered, and 3000 cc or more of fluid was given daily. In five days the abdominal symptoms had subsided. The urinary output which had been less than 500 cc daily at the time of his admission to the hospital, had returned to normal. The blood urea had dropped from 54 to 24 mg per hundred cubic centimeters of whole blood. Roentgenologic studies of the gastro intestinal tract did not disclose anything abnormal. The prostatic obstruction was relieved surgically and five months later the patient's health was good.

COMMENT

The laboratory data of these cases are given in the table. The patients were all men except one, classified as patient 8. They were all middle aged or getting well into old age. In cases 2, 4 and 6 the blood pressure was normal, in the rest of the cases it was definitely elevated. Arteriosclerosis was present in moderate to advanced degrees in all the cases. The blood urea determination on whole blood gave values that were higher than normal, if all these determinations had been made on the days on which the patients were admitted to the hospital, some of these values probably would have been higher. The values for the blood chlorides were high normal in all cases except case 10. In this case, chemical analysis of the blood was not made until the abdominal symptoms were subsiding. Severe degrees of anemia were not found in any of these cases. There was a moderate degree of anemia in cases 7 and 8. Case 1 was the only case in which the urine did not contain pus. Moderate or definite albuminuria was present in all the cases. Cases 5, 8 and 9 presented definite hematuria.

The absence of anemia in most of the cases probably indicated that the hyperazotemia had been present only a short time. The tendency to high concentrations of chlorides and normal carbon dioxide combining power of the blood distinguish this condition from obstruction of the upper part of the intestine, in which concentrations of urea in the blood are increased, the chlorides of the blood are decreased, and the carbon dioxide combining power of the blood is markedly increased. All the patients had arteriosclerosis, which was usually accompanied by hypertension and always by albuminuria. Erythrocytes were present in the urine in

cases 5, 7 and 9, and moderate to great numbers of leukocytes were present in the urine in all the cases except case 1. Aside from the fact that pyuria may indicate genito-urinary infection, the significance of the pyuria is not known. There was nothing to suggest a clinical picture of cystitis, pyelitis or pyelonephritis in any of the cases except case 8, in which the patient had had pyelitis many years before. This patient may have had a symptomless pyelitis or pyelonephritis ever since, but if she did she was unaware of it. Transient degrees of obstruction to a free flow of urine from an enlargement of the prostate gland, which is sufficient to produce stasis and a low grade symptomless cystitis, pyelitis or pyelonephritis, are possible in the rest of the cases. However, in the absence of such a history in all except case 10, this is not in keeping with clinical experience.

All these patients excreted less than normal amounts of urine during the first days of their stay in the hospital. Dehydration doubtless was a factor in the production of the oliguria, however, their illness was of too short duration to produce a degree of dehydration that would be sufficient to send the urinary excretion to such low levels. All the patients had been on regular, soft or liquid diets before coming to the hospital and in none of these cases was the nausea and vomiting severe enough to cause the patient to refrain from taking fluids by mouth. The oliguria is best explained on the basis of temporary partial suspension of renal function. In view of these considerations, it is reasonable to believe that these patients had decreased renal reserves. The kidneys were able to maintain normal excretory functions when no added loads were to be borne, but, with an added load, a temporary partial suspension of function occurred, with subsequent oliguria.

The mechanism that produced the signs and symptoms of obstruction of the lower part of the intestine is not easily explained. Renal insufficiency is not an adequate explanation, because the failure of renal function is not usually accompanied by symptoms of intestinal obstruction. It also is important to point out the fact that colonic obstruction of long standing does not produce changes in the blood chemistry if renal function is normal. Stones in the kidneys or ureters may produce colics which are difficult to distinguish from those which arise in the intestine. Such colics may be accompanied by deranged intestinal action and slight degrees of abdominal distention, but these symptoms never are as severe as they are in intestinal obstruction. It is of interest here to point out the similarity of this condition to that which frequently is seen after major surgical operations on a kidney. A few days after the operation the abdomen may become somewhat distended, so much so that intestinal obstruction may be feared.

An easy assumption would be that an enterocolitis was present in these cases and that bacteria or bacterial toxins pass from the colon to the kidney through the blood stream and secondarily involve a transient renal insufficiency. An enterocolitis is usually accompanied by fever and diarrhea, abdominal distention is not present. In long-standing infections of the colon, in which numerous ulcerations occur, as in chronic ulcerative colitis, abdominal distention, unless there is a perforation, is not a prominent symptom and renal insufficiency is rare. There are no data to support the view that this enterorenal syndrome is produced by infections in either the kidneys or the intestine, singly or combined. As a matter of fact, local disease in

either the kidneys or the intestine cannot be held responsible for the clinical picture.

There was definite arteriosclerosis present in all the cases. To assume that the renal insufficiency was produced by the arteriosclerosis is in keeping with clinical and pathologic experience. It is also conceivable to assume that both the ileus and the transient renal insufficiency were the result of synchronous local vascular disturbances in the kidneys and intestine or were the result of reflex action of the central nervous system. In the cases in which an exploratory laparotomy was performed there was a dilatation in the lower part of the ileum and right half of the colon, but no detectable circulatory disturbance. The absence of circulatory changes in the intestine is not convincing enough to assume that the syndrome was not the result of circulatory changes that were produced by vascular disease. The two exploratory operations were most valuable in the formation of a mental picture of what was going on in the abdomen, and in ruling out gross pathologic changes.

There was accompanying disease of the gallbladder in the two cases in which exploratory operations were performed. In case 3 the gallbladder was discovered to be filled with stones at the time of exploration, and it was therefore removed. Cholecystitis is often accompanied by gaseous distention of the abdomen. It must be admitted that the pathologic changes in the biliary tract may have been responsible for some of the symptoms in these two cases. However, in making further clinical studies a certain amount of data indicates that this transient train of symptoms is often superimposed on more definite and important organic diseases of the colon.

From a surgical point of view this clinical syndrome presents a problem of considerable interest and importance. Diseases in general fall into three main groups: those definitely nonsurgical, those definitely surgical, and those questionably surgical. Conditions of the type under discussion, when first seen by the consultant, seem to be without doubt surgical, and, unless one is watchful, the abdomen actually may be opened and explored to the chagrin of the surgeon; further study, on the other hand, will reveal that the condition is after all a matter for medical management—an ileus, to be sure, but one that has as its basis an upset of the chemical balance, which is the result of a multiplicity of causes. These causes may be summed up to be the result of senescent changes in all the organs, changes that are of such a nature that the patient skates continually on thin ice. The bodily reserve is diminished, this is particularly true of the systems whose function it is to eliminate body waste.

Because this syndrome concerns not only one part of the colon but all of it, there are complex factors which simulate acute obstruction of the small intestine. It must be recalled that a patient can go for days or even weeks with an almost total obstruction of the transverse, descending or sigmoid flexure of the colon, or of the rectum without very severe obstructive symptoms, and that in these cases the onset is rather sudden.

It is true that the physician cannot afford to miss the diagnosis of acute intestinal obstruction and that there may be an occasional case in which immediate operation is imperative. On the other hand, cases of this nature are necessarily bad risks and this must be kept in mind. With the perfection of the nonsurgical treatment, these patients may be tided over the acute intestinal obstruction with a medical decompression,

which has been described so well by Wangenstein, and there is rarely the necessity for immediate operation. By supplying fluids by the intravenous and subcutaneous routes, these patients can be kept comfortable and their chemical upset readjusted, studies can be continued, and in the event that operation is actually indicated, it can be carried out at considerably less risk. It will be found, however, in cases which fall within the realm of the type under discussion, that the patients will continue to improve under medical management, under readjustment of their chemical balance, that the syndrome is not directly the result of gross pathologic changes, and, last but not least, that operation can be avoided to the satisfaction of both the patient and the surgeon.

SUMMARY AND CONCLUSIONS

1 In ten cases, which are presented, there were symptoms suggesting obstruction of the lower part of the small intestine or of the colon.

2 These patients had an elevation of the concentration of urea in the blood, but in contrast to the alterations of blood chemistry, which usually occur in obstruction of the upper part of the small intestine, the values for the chlorides were high and the carbon dioxide combining power was normal.

3 If a patient presents the signs and symptoms of acute obstruction of the colon and if the value for the blood urea is high, the routine method of conservative administration of fluids and warm rectal irrigations should be followed, and stipes should be applied to the abdomen.

TREATMENT OF THE STUTTER TYPE
PERSONALITY IN A MEDICAL-
SOCIAL CLINIC

JAMES S. GREENE, M.D.
Medical Director National Hospital for Speech Disorders
NEW YORK

The National Hospital for Speech Disorders opened its doors seventeen years ago. Thousands of young men and women have availed themselves of our clinical services, 70 per cent of whom were given free treatment. Incidentally, since I opened the clinic we have handled over 15,000 stutterers, besides several thousand nonstuttering speech defectives.

Stuttering is herein defined as that speech phenomenon which is characterized (1) by tonic and clonic spasms of the vocal tract, which (2) result in conversational difficulty characterized by hesitancy. Theoretically, it is assumed that the stutterer type personality in one born with a special organic structure having constitutional factors which all but parallel the constitutional factors of the nonstutterer type. The stutter type is an extremely sensitive personality, in which the emotional range always overreaches that of the nonstutterer type. This human organism is not always destined to stuttering speech. Only an environment of opposition accentuating the native conflicts to which one is conditioned can evoke stuttering in its various forms, a neutral or favorable environment does not provoke or condition the individual to stuttering. The oppositional environment may be encountered either in early childhood or in adulthood. Consequently, a particular kind of unfavorable environment may evoke stuttering from this organic stutter type

either in childhood or in adult life. A specially created environment, such as our medical-social clinic, which is favorable, is the means by which the patient is unconditioned. That is, he is brought back to his initial stage or prestuttering state of security. My paper deals with the description of this special environment and the method of unconditioning the stutterer.

Years of observation and work have convinced me that stutterers are not speech defectives as conventionally understood. They can all speak normally under certain conditions. Their intermittent spasmodic speech is not the result of defective oralization but is conditioned in the stutter type of personality by highly emotionalized states of mind. They are agitated human organisms exhibiting a lack of forcefulness and decisiveness. Uncannily, they are moved back and forth across the borderline between emotional balance and emotional imbalance. The stutter type is further recognized by an incoordinated energy output. Their efforts, although numerous, are scattered. They shuttle from one thing to another. The usual result is ineffective social adjustment. All this is surmounted by extreme feelings of inferiority, culminating in chronic fear.

Opinions emanating from different points of view are centering on the fact that it is an emotional personality problem. For instance, Blanton,¹ Brown,² Solomon,³ Clark,⁴ and West⁵ say that stuttering is an emotional and personality disorder. Years ago I⁶ stated that the problem is centered in the field of human emotions.

The adult stutterer usually gives a history of having been a nervous, fearful child, an unduly irritable excitable child, often living in a psychoneurotic parental atmosphere surcharged with nervous tension. Such is the fertile soil or the agar-agar in which the stutter type is cultured.

From early childhood, conflicting emotions rule the stutterer's mind. His normal impulses are inhibited. He is a victim of dread, even terror, so that in the plastic years his doom is practically sealed. His personality development undergoes an ebb and flow that tends toward disintegration. In adult life the fears, morbidities and desolation associated with speech spread into every field of thought and activity. No one knows him as he really is. The attributes of his personality make no impression, because his stuttering is the focal point of interest. In short, stuttering is a pernicious living thorn in the flesh, which numbs the heart, distorts the processes of mind, paralyzes normal impulses with a searing sense of inadequacy, and imprisons human lives in hopelessness and uselessness, forever haunted by the victim's own unbearable sense of futility.

The following letter, to the editor of an evening paper,⁷ adds a graphic note to the stutterer's economic plight.

Sir: I am a stutterer, a year out of college. Searching for work proved fruitless. What chance has a stutterer? I want work, to earn the food I eat, the clothing I wear, and a bed.

and room But it seems utterly hopeless for me to meet the standards imposed by the merciless competition today Am I and other stutterers, doomed to a life eliminated from gainful activity? What hope is there for me to play a man's part?

JOHN STUTTERER

John Stutterer's plaint has echoed down through the ages Only recently Dr Albright, a Haverford College archeologist, brought from the ruins of the biblical town Beth Shemish a prayer on a small clay tablet reading as follows "Oh God, cut through the backbone of my stammering I desire that thou shalt remove the spring of the impediment"

Thus, the antiquity of stuttering is beyond question, because the antiquity of human emotions is beyond question Just as long as there are people whose emotions are intense, whose chronic fear reactions are dominant, so long will there be people of the stutter type and so long will they challenge ingenuity to get them out of their difficulty I feel sure that one cannot fully realize what stuttering speech means and does to an individual unless one has had an opportunity over a long period of time to deal with thousands of these cases

In and around greater New York alone the challenge is staggering Out of the six million population there are approximately 20,000 stutterers The report of the White House Conference on Child Health and Protection⁸ shows that 200,000 children stutter and that only one out of ten recovers during the elementary school period This immediately gives one an idea of the prospective number of young persons continually filtering in and increasing the vast army of adult stutterers Numerically there is a tremendous disproportion between physicians interested in this work and the patients in need of help

The treatment of stuttering has always been a baffling task because the basic problem of the stutterer was not viewed in the correct perspective Not only has the general problem been ill defined but the methods of treatment have been poorly unified It was concluded that an amalgamated therapy was essential Consequently, treatment had to be carried out both in the concrete and in the abstract form, physical and psychic, along broader lines These forms are carried out very satisfactorily through a special group approach, working from the general to the specific, from the group to the individual, or vice versa

Our medical-social clinic therapy has undergone many modifications and extensions It is best described as a composite therapy of a medical, psychologic, reeducational and social nature, the essential feature of which is the group approach⁹ The aim is to treat the stutterer's whole personality The group psychology has proved practical because, beyond a certain point, the individual problems of the stutter type become the problems of all

With children, speech training and methods of correction are carried out under medical supervision in school-clinic classes, in the form of a socializing task Concerning adults the volume of work points in only one direction In order to give equal opportunity to all, these patients must be dealt with *en masse* Social clinics under medical supervision, as community projects, will prove to be, as I have found, the most effective medium

In our clinic the initial interview with a stutterer, experience has taught us, is of far reaching importance The results of his entire course of treatment quite often depend on his initial contacts On his arrival we start rebuilding his personality at once Vainly he has been making the rounds of physicians, psychologists, schools and cults Consequently, he carries a chip on his shoulder and views one with suspicion In spite of that fact, he is made to feel that our medical-social clinic is not "just another place"

He is next given a physical examination Defects and poor hygiene are noted, recommendations are made by the physician in charge, and everything is done to improve his physical status

He is then, thirdly, given a speech test For that purpose we have a fully equipped radio department The patient speaks into a microphone answers questions or reads, and a record of his defective speech is made on a disk This recording serves a double purpose First, we know his speech condition before treatment is begun Second, subsequent records are made after a period of treatment, showing his improvement and the effect of the medical-social clinic modus operandi

Fourthly, he is examined by a psychologist Specialized tests given the patient afford us an idea of the individual's mental capacities Also, we try to obtain the degree of control and intensity of the individual's emotions To date we have no really accurate way of measuring emotions as we do intelligence, still, through a series of specialized tests, which we have devised, we are able to obtain an index of the stutterer's chronically exaggerated emotional status

The idea that a stutterer has an exceptionally high intelligence quotient is very prevalent, especially with the mothers of stuttering children This misconception is often used as a defense or compensatory mechanism and is just a case of reflected glory One stutterer (like A B P or S M or the late A B) may throw off enough rays of intellectual glory to illuminate thousands of other less prominent stutterers who are just regulation individuals

Concerning the superintellectuality of stutterers, West, Travis and Camp¹⁰ found that the median intelligence quotient for stutterers was 96.5, and that, as a special group, they were not mentally retarded

Our studies, based on the Otis self-administering intelligence test, are in agreement with these statements Our mean intelligence quotient for the group is 102.68 ± 1.1 and is slightly higher than the mean intelligence quotient for the nonstuttering population It was found also that the mean intelligence quotient of the males was 104, which is not significantly different from our total mean

Our broad amalgamating approach is eclectic We have proved to our satisfaction that it is inadvisable to adopt one therapy to the exclusion of all other procedures

In viewing stuttering as an emotional and personality disorder, we find that reeducational speech work per se is not enough Scientific treatment must develop a voluntarily controlled fulness and power in the weak and incompletely developed organizing parts of the personality How to integrate the disorganized individual is the problem Integration must take place so that the vital personality traits are placed in their proper relationship Throughout the treatment the

¹⁰ West Travis and Camp The Handicapped Child White House Conference Reports 1931

interest of the doctor and the patient must be focused on the total personality

This does not mean that it is unnecessary to do anything for the stutterer's speech. According to some theoretical, psychologic and psychiatric points of view, stutterers should be cured without speech work. Practically, that is not so. Although there may not be any inherent virtue in speech work still it is the only medium for correcting vocal tract remediable maladjustments. Also, negative speech habits that have become ingrained must be corrected.¹¹ One cannot talk a stutterer out of his habit spasms. Technical faults respond to reeducational pressures, not to theoretical discourse alone. Concentration on style or good speech acts as a distraction, so that fear is relegated during the development of good speech habits. The physiology of breathing is easily explained and comprehended, so that a normal calm manner of breathing is readily adopted. Breath control is a wonderful factor in emotional control.

If the patient understands the simple anatomic and physiologic functions of the vocal tract, it is very effective in removing many mysterious speech interferences. When the stutterer's spasms of abdomen, chest, throat or mouth are viewed in their proper light, his reason comes to the fore. Physical obstructions to speech are reduced in number, and relaxation is effected.

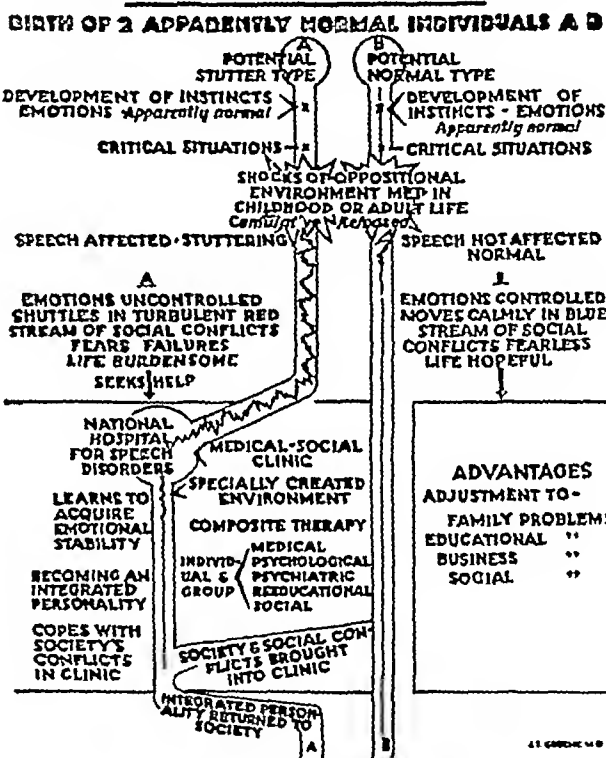

Alternating group and individual reading is an excellent means of gaining confidence. Emotions are tranquilized. Thoughts are formulated without fear. Haze is gradually eliminated and finally discontinued.

Muscular relaxation and coordination are important group activities which stutterers find hard to effect. Stutterers, depending on the degree of their excessive and inconsistent discharge of emotions, show pronounced differences when compared to nonstutterers in their responses to muscular contraction and relaxation. They belong to a naturally retarded performance group. They demonstrate stuttering not only in their speech but in other ways as well. Their movements are jerky instead of regular, excessive or diminished. Shortly after awakening, some stutterers are unable to bring their speech mechanism into action. In fact, they are muscularly in a state of twilight sleep. They speak worse than usual, and often, until they get themselves muscularly warmed up, are hardly able to speak. In others, the chronic emotional and muscular tensions are so pronounced that the stutterer seems to be made of one piece—set and rigid. This rigidity is readily noticed when he tries to speak. The majority bring into play unnecessary and excessive muscle movements—a faulty muscle balance. There is considerable difficulty in controlling fine and gross muscle movements.

A mother frequently complains that her stuttering child talks badly, walks badly and does all things more or less badly. He is the fearful and clumsy one in the family. Adults complain of jerky muscular movements and an inefficient energy expenditure. Their golf and tennis is not spectacular. They drive their automobiles in a spasmodic style. We have had, like others,¹² stuttering musicians. A violinist may get glued to a note and repeat it several times spasmodically. A piano player's finger seems to stutter repeatedly on a note before striking the next one. A typist may likewise stutter on her machine.

All this inefficiency prescribes the necessity of reorganizing the stutterer. For this purpose we have introduced group activities of rhythmic coordination exercises to music. Groups are taught to combine and alternate muscular contractions with progressive degrees of relaxation. Thus they learn to counteract an excess of incoordinated activity and bring quiet, peace and tranquility to the nervous system. They gradually become inculcated with a sense of rhythm and harmony, which is seen in diminished tension and gracefulness of movements. They acquire a certain amount of abandon which in turn is reflected in their speech. The major problem, however, is to change the personality and develop emotional control.

PLAN OF RECONSTRUCTION OF THE STUTTER-TYPE IN A MEDICAL-SOCIAL CLINIC

Plan of reconstruction of the stutter type in a medical social clinic

Every stutterer's life is one of introversion, repression and frustrated desires. Infantile attitudes and conflicts remain with him. He finds no satisfactory solution for his problem. The psychiatrist's task is to discover the underlying chain of causes. He must replace the infantile attitude with an adult personality. We found that a departure from the traditional therapy was necessary. The problem is rather intricate and not easy.

Psychoanalytic treatment of the usual type wherein one tries to verbalize thoughts is an almost impossible task for a stutterer. The fostering of freedom and rapport between the analyst and the stutterer, consequently, is more than usually drawn out. Our patients who have been subjected to psychoanalysis before coming to us state that the process is long and costly and is not productive of desired results. The patient, while the analyst sits silently by, struggles with his free associations and finds transference difficult. Moreover, the analyst seldom reaches the constructive phase of

¹¹ Dunlap Knight, *Habits—Their Making and Unmaking* New York, Liveright Publishing Corporation 1932.
¹² Blumel C. S. *Mental Aspects of Stammering* Baltimore Williams & Wilkins Company 1930.

his treatment. Since his procedure is only psychic, it is not complete without the physical reeducational therapy. This especially holds true if the psychoanalyst does not consider all immediate and secondary intrinsic speech difficulties.

I know of many stutterers who, during analysis, kept asking themselves "When will the doctor do something for my speech?" In every stutterer's case his defective verbal production is a fixed living thing, and, as pointed out, every form of treatment must consider that phase in actual practice, our psychiatric treatment does so.

Our specially created atmosphere¹³ is one in which informality, encouragement and sympathy hold sway, one which radiates calm, peace and tranquillity. The stutterer is put at his ease in such a way that perhaps for the very first time in his life he appreciates a hitherto unknown spiritual peace. In such an atmosphere his psychoneurotic symptoms, which complement his stuttering speech, respond readily to direct and indirect suggestion. Old habits of a nonsocial, egocentric, fearful individual are broken down. Feelings of shame and secretiveness are brought out into the open. To effect this, we have introduced a special procedure in our psychiatry. I call it "open door" or group psychiatry, and it has proved to be very practical and beneficial. The patient consults with the doctor in a large room, the door remaining open. It is possible to insure a sense of intimacy and privacy by placing the desk at the far corner of the room. In spite of the fact that it is an open room, it is amazing how quickly the patient adjusts himself to this open door psychiatry and is not perturbed. Minor emotional disturbances and even major conflicts are successfully resolved. However, when deemed necessary, a closed door interview is given, so that unconscious difficulties that have been evaded are gotten under control.

The open door method has one valuable asset. It makes it possible for the doctor to call in other patients, who happen to pass the open door, and utilize them in various ways. Their presence is most helpful, when necessary, they serve as eager listeners or participate in the discussion. The personal aspect of secret problems is eliminated and the patient realizes that these problems are not his alone but belong to the stuttering fraternity as a whole. Almost unbelievable reconstruction takes place within a short time and an integrated personality then comes into being.

The importance of social therapy, which goes a long way toward adjustment, is very pronounced, especially for working boys and girls who attend our evening clinics. These clinics have been carried on since the opening of the institution. Since stutterers are afraid "to go places and do things," in brief, are afraid of social contacts, we reverse the situation by bringing society to the stutterer.

In our medical-social clinic, all patients automatically become members of our clubs. No matter what their interests, we try to furnish the outlet so that self-expression becomes a matter of course. We have debating and literary clubs, a dramatic club, a class in language and word study, one in eukinetics, a choral singing club, and other enterprises. The activities arising from these are periodic dinners, entertainments, dances, outings and the like. All of these specially created socializing agencies tend to bring about a complete metamorphosis in the stutterer's life, so that he can cope with oppositional environments.

Besides the regular medical, psychologic and reeducational activities, Wednesday evening is devoted to an important meeting of the entire clinic, forming an association called the Greene-Ephphatha Club. It takes the form of a business meeting with a planned program and has a chairman, secretary and minutes. Topics are assigned or chosen. The speeches are short and all voluntary. It takes courage to volunteer, consequently, as a therapeutic procedure, it is of great value. Occasional criticism and constant encouragement is the order. A few remarks on the outstanding feature of the evening or on some aspect of the stutterer's personality made by the director concludes the meeting. There is an intangible something at these meetings that gives the stutterer an exalted, enthusiastic attitude and a definite feeling of social security which is difficult to describe. Into these meetings is put a great deal of practical psychology, so that each patient in the presence of his fellow stutterers, where there is always some one worse than he is, goes through a speech crisis, which is a spiritual uplift. He thereby gets his first hold of confidence in a speech situation of a vital nature. Here he emerges from his introverted shell in a form of spiritual conversion, faith and belief in himself become crystalized. It establishes the foundation that reconditions him to subsequent social contacts.

Our dramatic club gives the patients additional opportunities for social adjustment. They are trained to acquire stage poise in order to achieve that fluid flow of personal adjustment necessary to changing conditions. We have developed latent talent. A group of ex-stutterers are now giving little plays in the different settlement houses around town.

CONCLUSION

- 1 The stutter type personality is born with a highly emotionalized organic structure.
- 2 Only an oppositional environment to which he becomes conditioned may evoke stuttering, which is not a speech defect but a physical protest of an instinctive fear emotion.
- 3 The stutterer's problem is primarily one of psychologic reconstruction, emotional control, and integration.
- 4 The vast number of stutterers requires special group treatment in a specially created environment wherein they acquire a spiritual tranquillity.
- 5 The most practical agency for unconditioning the stutterer is one encompassing medical, psychologic, psychiatric, reeducational and social therapies, which I have developed in our medical-social clinic.

NOTE—A practical demonstration of the work of the medical-social clinic was given through the presentation of ten patients. They gave short impromptu talks on topics suggested to them by the audience. These patients demonstrated the permanence of their cure, having received treatment as far back as sixteen years, fourteen years, twelve years, and so on down to six months.

VALUE AND LIMITATIONS OF SPINAL
PUNCTURE IN CEREBRAL HEMOR-
RHAGE OF THE NEW-BORNABRAHAM LEVINSON, M D
CHICAGO

During the past few years, numerous investigators have studied the value of spinal puncture in the diagnosis and treatment of cerebral hemorrhage in the new-born. Sharpe concludes that bloody fluid is an indication of cerebral hemorrhage, that clear fluid practically excludes such a diagnosis, and that whenever the cerebrospinal fluid is bloody, repeated punctures should be done. In a recent report he¹ says

If free blood is present in the cerebrospinal fluid, repeated lumbar punctures of spinal drainage are immediately instituted, just as in adults and children with head injuries, in order to permit the free blood to escape and thus avoid the great danger not only of death but in some cases the even more tragic result of spasticity and retarded mentality. If the diagnostic lumbar puncture reveals clear cerebrospinal fluid, the physician knows almost certainly that no intracranial hemorrhage has occurred and that the signs were most probably due to a temporary cerebral edema of varying degree.

Investigations indicate that fresh blood in the cerebrospinal fluid of the new-born, especially if the color remains constant in successive portions of the fluid, suggests the existence of a cerebral hemorrhage, but that bloody fluid is not a positive diagnostic criterion, since the blood may be due to puncture trauma. Clear cerebrospinal fluid, on the other hand, does not exclude cerebral hemorrhage, especially of the ventricles.

It is difficult to determine the importance of xanthochromia, or yellowish discoloration of the cerebrospinal fluid, in cerebral hemorrhage. Greengard, Lifvendahl and I² found that 88 per cent of more than 100 new-born infants had xanthochromic fluid, the benzidine and van den Bergh tests were negative in most of these. In some of the cases in which xanthochromic fluid was obtained during life, cerebral hemorrhage was found post mortem, in others, cerebral hemorrhage was not found. I believe that xanthochromia with a positive benzidine test speaks for a cerebral hemorrhage and that without such a positive reaction no diagnosis of cerebral hemorrhage can be made, as only meningeal congestion may be the cause.

There was also a variation in the amount and pressure of cerebrospinal fluid removed from patients with cerebral hemorrhage in the series studied, 5 cc being taken as the greatest normal amount and 6 mm of mercury as the maximum normal pressure, in new-born infants. In most cases of cerebral hemorrhage the amount obtainable and the pressure were increased.

I believe that, at the present state of our knowledge, bloody cerebrospinal fluid is not pathognomonic of cerebral hemorrhage. Of greater value in diagnosis is clear xanthochromic fluid with a positive benzidine test, and increased amount and pressure. However, since even clear cerebrospinal fluid does not exclude cerebral hemorrhage, the diagnostic value of lumbar puncture in cerebral hemorrhage is limited.

In order to evaluate the therapeutic importance of spinal puncture in cerebral hemorrhage of the new-born, it is necessary to consider the pathology and symptomatology of cerebral hemorrhage in the new-born.

The hemorrhage varies in location and extent. The most frequent site of hemorrhage is the subarachnoid space. Meningeal hemorrhage was present in all the cases that Saphir and I³ studied irrespective of involvement of any other part (table 1). In prematurely born infants the hemorrhage is often around the pons and cerebellum.

Do all patients with cerebral hemorrhage die or develop diplegia, hydrocephalus or idiocy? Our records indicate that such is not the case (table 2). Of 292 infants with cerebral hemorrhage among 1,527 prematurely born infants admitted to the Sarah Morris Hospital for Children from 1927 to 1934 inclusive, 173 died but 119 survived. About 60 per cent of those who survived had no evidence of brain injury, as shown by Hess, Mohr and Bartelme⁴ and their associates.

If one remembers that most instances of cerebral hemorrhage of the new-born are limited to the meninges and that in only a very small number is there bleeding into the cerebral substance proper, one can also see

TABLE 1—Cerebrospinal Fluid in the New-Born

	Normal	Cerebral Hemorrhage
Amount obtainable	0.5 to 5 cc	Usually increased
Pressure	1 to 6 mm of mercury	Usually increased
Color	Clear or xanthochromic	Xanthochromic or bloody but may be clear
Cells	0 to 3 lymphocytes	Usually increased red and white blood cells
Benzidine test	Negative	Positive in bloody fluid in both uncentrifugated and centrifugated supernatant portions Usually positive in xanthochromic fluid Negative in clear fluid

how recovery may occur without leaving a scar. Saphir and I studied the question of meningeal reaction in cerebral hemorrhage. We found no leukocytic reactions in any of our cases, either in the meninges or in the brain. Only occasionally was there an increase in endothelial cells in the meninges. We therefore believe that in some cases the cerebral hemorrhage is absorbed without scarring.

The symptoms of cerebral hemorrhage during the neonatal period are not always the same. They may be classified into two types—irritative and somnolent—although some infants exhibit a combination of the two types.

The irritative type is characterized by great restlessness, a high-pitched cerebral cry, moaning, and a pained expression. The extremities may be spastic immediately after birth, although the spasticity may not be manifested for some time later. Facial paralysis may be present, although it should be remembered that not every instance of facial asymmetry or even every convulsion in the new-born means intracranial hemorrhage. Nystagmus may be present. The anterior fontanel not infrequently bulges in this type of hemorrhage.

2 Levinson, Abraham, Greengard, Joseph, and Lifvendahl, R. A. Cerebrospinal Fluid in the New Born. *Am J Dis Child* 32: 208 (Aug) 1926.

The somnolent type of cerebral hemorrhage, which is most frequent in prematurely born infants, is characterized by apathy, a subnormal temperature, difficulty in swallowing, fleeting cyanosis, and sometimes a depressed fontanel.

Infants suffering from cerebral hemorrhage refuse food entirely or take very little nourishment. Because such infants do not take food well, they become dehydrated very rapidly.

With the exception of the fleeting cyanosis, the skin of infants suffering from cerebral hemorrhage is usually dusky red, the duskiess being constant and most apparent on the trunk, the face at times being even pale. If there are active symptoms of cerebral hemorrhage, the duskiess may persist for days or even weeks. Retinal hemorrhages are sometimes present, these often result in optic atrophy.

If the cerebral hemorrhage is part of a hemorrhagic diathesis, there may be bleeding from the umbilicus, mouth and rectum. The coagulation and bleeding time of the blood are prolonged in these cases.

It is thus seen that not all cases of cerebral hemorrhage are of the same type, clinically or pathologically, further, that some meningeal hemorrhage may absorb without leaving any scar, even if no treatment is used. I therefore believe that in the somnolent type of cerebral hemorrhage spinal puncture is not necessary and, if done once, should not be repeated. In the irritative type, however, spinal puncture should be done for therapeutic purposes and may even be repeated.

The most important part of the treatment in cases that have been diagnosed as, or are suspected of being, cerebral hemorrhage is, I believe, complete rest. The infant should not be permitted to nurse from the mother but should receive the feedings by bottle, spoon or

the baby. Oxygen by catheter is useful, but the supply of oxygen is uncertain, a small oxygen tent may be useful. Hess has recently devised a flow meter for administering oxygen to prematurely born infants in the incubator. I use oxygen without carbondioxide in my cases.

If the patient has convulsions, sedatives, such as sodium bromide or sodium amytal should be given rectally. Introduction of a hypertonic solution of sodium chloride or from 10 to 15 per cent dextrose solutions, intramuscularly, may also be used for relief of increased intracranial pressure.

U S P ETHER FROM LARGE DRUMS AND ETHER FROM SMALL CANS LABELED "FOR ANESTHESIA"

COMPARISON IN SEVEN HUNDRED AND TWO
OPERATIONS

ELLA M HEDIGER, M D

AND

HARRY GOLD, M D

NEW YORK

The United States Pharmacopeia, in the article on ether, (U S P X) makes the following statement in italics: "Caution—Ether to be used for anesthesia must be preserved only in small, well-closed containers, and is not to be used for this purpose, if the original container has been opened longer than twenty-four hours."

This statement gives official sanction to the general practice in this country of using anesthetic ether chiefly in small cans of one-fourth and one-half pound. What remains in the can is usually regarded as unfit for anesthesia on the following day. Ordinary U S P ether has been in use for many years in the laboratory of pharmacology of Cornell University Medical College for anesthesia in animals. Although this ether was taken from cans which had been opened many times, no ill effects were observed, but a systematic study of the question was not made.

Why should ether be considered unfit for anesthesia twenty-four hours after the container is opened? In a recent study¹ an answer to this question was sought from (a) the results of chemical tests for deterioration and (b) the experience of anesthetists.

The results of that investigation failed to reveal sufficient evidence to justify the twenty-four hour clause. The inquiry among surgeons and anesthetists disclosed that adherence to the practice directed by the United States Pharmacopeia has been so general that one does not readily find an anesthetist who has made observations sufficiently controlled to afford an acceptable judgment regarding U S P ether taken from metal containers which had been opened several days prior to their use for anesthesia. Several anesthetists declared that they had used ether from cans that had been opened several days and that they had not observed any special danger in its use. On the other hand, many feel that such ether is undesirable, and among these the most divergent opinions prevail regarding the nature of the danger. Some state that the ether becomes very

dropper. The feeding portions should be small, so that the baby will not be fatigued and cyanosis thus be produced. If breast milk is not available, diluted milk should be given. Physiologic solution of sodium chloride should be given subcutaneously for dehydration. The body heat should be maintained by keeping the infant in an incubator or by applying external heat by means of hot water bottles. Intramuscular blood is an accepted procedure.

In fleeting cyanosis either oxygen or a mixture of 95 per cent oxygen and 5 per cent carbon dioxide has been advocated. The Henderson apparatus would be very useful for this purpose, but the mask is too heavy for

From the Department of Surgery and the Department of Pharmacology of Cornell University Medical College.

The authors are indebted to Dr. William DeWitt Andrus for his cooperation in carrying out this study.

¹ Gold, Harry and Gold, David. Stability of U S P Ether After the Metal Container Is Opened. J. A. M. A. 102:817-820 (March 17) 1934.

irritant, some, that it becomes very toxic so that extremely small quantities produce symptoms of collapse, others state that they have found it loses some of its anesthetic properties so that with it satisfactory anesthesia cannot be induced. The view regarding the dangers of ether for anesthesia from a container that has been opened for some time seemed to be based chiefly on reports in the literature describing toxic reactions produced by samples of impure ether which failed to comply with the present U S P standards.

The literature on the subject of deterioration of ether as determined by chemical tests also failed to supply a rational basis for the twenty-four clause Baskerville,² who more than twenty years ago made some notable contributions to the chemistry of the oxidation of ether, urged the use of ether from small containers so that the entire contents might be used at one time because of the possible danger of deterioration after opening of the container. His emphasis on rapid deterioration was not justified by his own experiments, as in them ether was exposed for periods of months under extreme conditions before the tests for deterioration were made. No reports could be found in the literature to show that opening the container leads to rapid chemical deterioration of U S P ether in metal cans, although the literature abounds in warnings against the danger of using ether for anesthesia which has been kept under those conditions.

In the previous study¹ it was shown that ether, whether labeled "U S P" or "for anesthesia," does not deteriorate rapidly under ordinary conditions when the metal cans are opened, part of the contents removed and the remainder stoppered with cork, even though no precautions are taken against exposure to air other than stoppering. Although the containers had been opened and again stoppered many times during periods of from several days to several months, the U S P X tests were negative for aldehydes, peroxides and acids. These results were obtained with a group of more than fifty specimens of ether supplied in containers varying from quarter-pound cans to 55-pound drums by five manufacturers or distributors. In many cases the labels stated that the cans were copper lined, were so treated as to become "catalytically inert," or contained a coil of steel wire to inhibit oxidation. In the case of the steel drums, as well as many of the tin cans, no special claims regarding the quality of the containers were made. The results were identical in all.

It should be stressed that the foregoing statements regarding the stability of U S P ether apply to the product as supplied in metal containers at the present time by the outstanding manufacturers in this country, to whom a large share of the credit is due for the work that has made such relatively stable ether available on a large scale.

Since a 27-pound or 55-pound drum of ether would last only a week or two in the average hospital, there seemed to be no justification for purchasing ether in hundreds of quarter-pound or half-pound tins at a cost five or six times that of ether in a large drum, which could easily be supplied to the operating rooms daily in quarter-pound tins by the hospital pharmacist. A smaller container such as a 5-pound tin, which is easier and somewhat safer to handle, might in some cases prove more desirable than the larger drum.

However even though ether labeled U S P is the official ether of anesthetic quality, the view prevails that

such ether is not suitable for anesthesia and that an especially purified ether is necessary for this purpose. To distinguish these two types of ether, the words "for anesthesia" appear on the cans of anesthetic ether. In the minds of many, this would exclude the ether in drums from use for anesthesia because it bears only the label "U S P" and not "for anesthesia." Therefore, before anesthetists could feel free to use U S P ether for anesthetic purposes, obtained from a large drum, it was necessary to have the answer to another question, namely, is there any difference that can be detected in patients between the effects of U S P ether taken from large drums which are opened from time to time and the effects of ether labeled "for anesthesia" taken from small containers opened less than twenty-four hours?

This formed the subject of the present investigation, which was carried out on surgical patients in the New York Hospital.

PLAN OF INVESTIGATION

The study was made with the "blind test." Those administering the anesthetics to the surgical patients were unaware of the source of the ether and identified the specimens in terms of code numbers in their records. The daily orders for ether were filled in the department of pharmacology. The supply was delivered to the operating rooms in quarter-pound and half-pound cans of ether bearing a special uniform label with the date and time the can was filled and a consecutive code number. All the cans were tightly stoppered with ordinary cork. Ether remaining in the small can after twenty-four hours of the time it was filled was not used for anesthesia during this study, thus afforded more uniform and comparable conditions for the comparison of the two types of ether. At irregular intervals the drum ether was tested by the U S P X tests for peroxides, aldehydes and acid (litmus test). In addition, all ether was tested daily by other extremely delicate tests³ for both peroxides (solution of potassium iodide) and aldehydes (Nessler's reagent).

The U S P bulk ether as supplied by a well known manufacturer was bought in 55-pound drums. For convenience of filling the daily supply of quarter-pound and half-pound cans, the ether in the drum was transferred to 5-pound tins which had previously contained ordinary U S P ether (supplied by Emer and Amend). These were thoroughly rinsed with the fresh drum ether, then filled with the latter, stoppered with cork, placed on a shelf in a dark room and stored at room temperature. This ether was compared with the ether labeled "for anesthesia," which was obtained in quarter-pound and half-pound sealed cans manufactured by the Mallinckrodt Chemical Works, Merck & Co. and E. R. Squibb & Sons. The necessary number of cans were opened for the daily supply and the contents transferred to the quarter-pound cans bearing the uniform label, after they were thoroughly rinsed with the fresh ether. In general, the two types of ether were alternated daily, although no fixed order was followed, in order to avoid the danger of possible detection by the anesthetist.

³ In the test for peroxides 1 cc. of a colorless 10 per cent solution of potassium iodide was added to 10 cc. of the ether in a glass stoppered cylinder previously rinsed with the ether. The absence of a yellow color after shaking from time to time during five minutes indicates that not more than a trace of peroxide, if any is present (result designated negative). In the test for aldehydes 3 cc. of Nessler's solution (U S P X) was added to 20 cc. of the ether in a glass stoppered cylinder previously rinsed with the ether. The absence of almost immediate change in color after shaking and allowing layers to separate indicates that not more than a trace of aldehyde, if any is present (result designated negative).

² Baskerville, Charles. Ethyl Ether for Anesthetic Purposes. *Am. Druggist & Pharmaceut.* Rec. 5-162, 1910.

A complete record of all cans of ether sent to the operating rooms was kept in the department of pharmacology. In addition to this open record, a sealed envelop containing a duplicate record was sent to the anesthetist with the daily supply of ether. These sealed envelops were opened for the purpose of identifying the specimens of ether only after the work had been completed and the results had been analyzed from records which gave no clue as to the source of the ether.

The anesthetics comprising this study were conducted by nine experienced anesthetists. A group of 113 patients received ether alone and in these the open cone drop method was used. A group of 589 patients were anesthetized by a mixture of anesthetics comprising various combinations of tribrom-ethanol, ethylene, nitrous oxide and ether. In a large proportion of the latter group some form of rebreathing method was used for the administration of the ether. A record of the anesthesia was made by the anesthetist on a special form provided for each patient. It was filled out at the time of the operation and further notes were added as the additional observations were made. These special charts were employed for the analysis of the data when the work was completed. This form supplied the following significant data: the diagnosis, the type of operation, the name of the anesthetist and surgeon, the physical status of the patient before operation, the drugs given prior to anesthesia and the time of their administration, the amounts of anesthetics other than ether, the amount of ether used and the code number of the specimen, the character and duration of the induction stage, the stage of maintenance and the stage of recovery, and postoperative complications up to the time of discharge from the hospital. Special attention was paid to such factors as coughing, excessive mucus, undue struggling, vomiting, cyanosis, signs of collapse, unduly prolonged induction stage, and difficulty in obtaining sufficient anesthesia or relaxation.

These special charts also provided a space for a general estimate by the anesthetist of the quality of the anesthesia in the individual patients, which was recorded immediately after the operation and was expressed as "satisfactory" or "unsatisfactory." These designations were intended to express a judgment on the part of the anesthetist which would take into account factors which might reasonably influence the character of the anesthesia, as the temperament of the patient, the character of the operation, and the type of preliminary medication. Anesthetics in which the induction, the maintenance and the recovery were smooth and uncomplicated by struggling, coughing, vomiting or other special reactions made up by far the larger part of the group of "satisfactory" anesthetics. However, some cases pre-

sented special and undesirable reactions were also placed in the group of "satisfactory" anesthetics. The plan may be made clearer by a few illustrations.

An anesthesia was described as "satisfactory" when a patient who was unduly nervous struggled violently during the induction but passed through the other stages of anesthesia without any special symptoms. If vomiting occurred during the induction stage in a patient who had received suitable preoperative preparation, the anesthesia was judged "unsatisfactory," whereas if vomiting occurred in an emergency operation in which the stomach was not empty the anesthesia was considered "satisfactory," provided it was normal in other respects. If cyanosis developed during the stage of extremely deep anesthesia purposely induced as is sometimes requested by the surgeon during a difficult cholecystectomy, the anesthesia was not judged "unsatisfactory," whereas if the anesthetist found it impossible to induce a normal depth of anesthesia without cyanosis the anesthesia was considered "unsatisfactory."

With the exception of the foregoing cases, anesthetics were regarded as "unsatisfactory" if the anesthetist's efforts to maintain smooth, even and uncomplicated anesthesia proved unavailing. In the designation "unsatisfactory" it is not intended to imply that the special symptoms were due to the anesthesia alone or to the ether alone, for differences in susceptibility of patients were not excluded, and other anesthetics in addition to ether were used in a large proportion of the cases. Nevertheless ether was present in these mixed anesthetics, and it was felt that, if significant differences between drum ether and ether labeled "for anesthesia" exist, they would be revealed in the records which give an account of the foregoing observations. We realize that the subjective elements involved in the

classification of anesthetics as "satisfactory" and "unsatisfactory" introduce variable factors with a considerable margin of error and that under ordinary circumstances opinions which are based on such estimates are vitiated by the bias of the anesthetist who knows the source of the ether. The significant point of this study is that the general appraisals were made entirely free of possible prejudices and preconceived notions regarding the relative value of different types of ether, since those who made them had no knowledge of the source of the ether.

RESULTS

The analyses are based on the results obtained in 702 surgical patients. There were nine additional patients who were not included because the records were not sufficiently complete. In all, 349 patients received the drum ether and 353 the small can ether labeled "for anesthesia." Table 1 shows the distribution of the more common types of operations in patients who received drum ether and those who received small can ether labeled "for anesthesia," in the group of mixed anesthetics. Table 2 shows a similar analysis in the group of 113 cases in which ether was the sole

anesthetic agent. While the types of operations were not equally distributed between the groups of patients receiving the two types of ether, there is a large enough representation of the more common operations in the two groups to justify the deductions that are made in this study.

Table 3 shows the distribution of the cases of vomiting during the induction and the maintenance stages of anesthesia in the total number of 702 patients. As may be seen, there were in all thirty patients who vomited during one or the other of these stages, and those receiving the small can ether labeled "for anesthesia" constituted twenty of these thirty cases. The number of cases is much too small for the results to have any statistical value, but as far as they go they do not give any suggestion that ether taken from a large drum is more irritant and more apt to induce vomiting than ether labeled "for anesthesia."

An attempt was made to ascertain whether there is any difference between the quantities of the two types of ether necessary for anesthesia. There are so many variable factors in an analysis of this kind that again the statistical value of the figures obtained in a relatively small group of cases is open to question, especially in the group in which ether was not the sole anesthetic agent. We examined the results in the group of 113 patients who received ether alone, and we present them for what they are worth. The amount was recorded in forty-four cases in which the small can ether labeled "for anesthesia" was used and in fifty-nine cases in which the drum ether was used. The amount of small can ether ranged in the different cases from 0.25 ounce to 10.5 ounces, with an average of 3.26 ounces. The amount of drum ether ranged from 0.25 ounce to 9 ounces, with an average of 2.16 ounces. It seems extremely unlikely that these figures represent actual differences in the anesthetic potency of the two types of ether. In any case, however, they lend no support to the view commonly expressed that ether taken from a can which has been opened some time loses much of its power to induce anesthesia.

An analysis of the data on the postoperative complications revealed comparable conditions with the two types of ether. There were nine deaths in the group receiving drum ether and seven deaths in the group receiving small can ether labeled "for anesthesia." The nature of the complication in the fatal as well as in

the nonfatal cases is presented in table 4. The only death caused by a pulmonary complication occurred in the group which received the ether labeled "for anesthesia." Since it was due to a pulmonary infarction, it is extremely doubtful whether the ether was responsible for it. Excluding this case, there were no deaths in the whole series which could by any possibility be charged to either type of ether. There were six cases (all nonfatal) of postoperative pulmonary complications in the group receiving drum ether, and four cases (three nonfatal and one fatal) in the group receiving small can ether labeled "for anesthesia." If the two cases of bronchitis that occurred in patients who gave a history of chronic cough before the anesthetic was administered are omitted, the results in regard to postoperative pulmonary complications are essentially identical for the two types of ether.

Two additional groups of data have been analyzed, which present the most significant facts of the present study, namely, the chemical tests of the drum ether and the relative incidence of "satisfactory" and "unsatisfactory" anesthetics in the cases in which the two kinds of ether were given. The results of the chemical tests are presented in table 5. The contents of three 55-pound drums of U S P ether had been transferred to twenty-five 5-pound tins, which were opened from time to time for the filling of the quarter-pound cans. The number of times the tins were opened and the intervals between the first opening and the last testing are stated in the table. Extremely delicate tests, capable of detecting traces of aldehydes and peroxides, gave negative results as long as sixty-eight days after the tins were first opened. Not one of the twenty-five

tins showed signs of chemical deterioration of the ether. These confirmed the results obtained in the previous study.¹

In table 6 the incidence of "satisfactory" and "unsatisfactory" anesthetics in the cases in which U S P drum ether was the agent is compared with that in the cases in which small can ether labeled "for anesthesia" was used. As has already been stated, these designations expressed a judgment of the anesthetist as

to the quality of the anesthesia made at the time of the operation and without knowledge of the source of the ether. It is clear from this table that the results are identical with the two kinds of ether.

The results obtained in three cases illustrate in a striking manner how differences in the behavior of the patient may be a source of error in judging the quality

of an anesthetic agent. One of these came to operation on two occasions, during both of which small can ether labeled "for anesthesia" was administered. After the first operation performed for adhesions, recovery was uneventful, whereas after the second one, for intestinal obstruction, a postoperative pulmonary infarction developed. In the second patient a convulsive seizure developed during the induction stage, although the period of

maintenance was even and uneventful. The ether in this case was from a quarter-pound tin labeled "for anesthesia" similar to that used in many other cases in this study. In the third case it was found impossible to obtain sufficient relaxation to perform a hemorrhoidectomy during anesthesia with nitrous oxide and 6 ounces of drum ether. Small can ether labeled "for

anesthesia" was then substituted, but the anesthesia was discontinued when relaxation was not obtained after 6 ounces of this had been administered.

SUMMARY AND CONCLUSIONS

1 This study shows that U S P ether as supplied at the present time in large metal containers does not undergo rapid chemical deterioration when the container is opened. Deterioration products were not found even sixty-eight days after the container was first opened. These results confirm a previous report.¹

2 The study of 702 surgical anesthetics shows, furthermore, that the anesthetist is unable to distinguish the effects of U S P drum ether from those of ether obtained in small cans labeled "for anesthesia," by the reactions of surgical patients, provided the anesthetist does not know the source of the ether he is using. Under those conditions, the anesthetist was unable to distinguish, for example, the ether in a quarter-pound tin labeled "for anesthesia" from ether taken from a 55-pound drum sixty days after it had first been opened.

3 The U S P drum ether that we used in the present study was therefore as satisfactory for anesthesia as the ether in small tins labeled "for anesthesia." We believe that this statement is applicable to U S P ether in large containers from at least five other sources, which, although not labeled "for anesthesia," was found in a previous study¹ to be similarly resistant to chemical deterioration after the containers were opened.

HYPERPARATHYROIDISM CLINICAL PICTURE IN THE FAR ADVANCED STAGE

SECOND REPORT

ARMAND J. QUICK, PH.D., M.D., MILWAUKEE; AMBROSE HUNSBERGER, JR., M.S., ELDRIDGE L. ELIASON, M.D., AND HARRY HUDSON, M.D., PHILADELPHIA

In 1931 we¹ presented a case of hyperparathyroidism that had advanced to such a stage that every bone showed cysts and decalcification, and some of the long bones, especially the femurs, almost complete demineralization. Owing to the numerous fractures early in the disease, and the extreme softness of the bones later, marked deformities had occurred, leaving the patient a hopeless cripple. When the decision had been made to do an exploratory operation with the objective of finding a parathyroid tumor, no other hope was entertained than to stop the progress of the disease. Not only was this hope realized but the patient has been restored to a degree that seemed unbelievable at the time of his first operation. Since the case forcefully illustrates what can be expected from the surgical treatment of hyperparathyroidism arising from an adenoma of this gland, the history subsequent to the first publication is presented.

SUMMARY OF CASE

J. M., a well developed man, 6 feet (183 cm.) tall and weighing 200 pounds (90.7 Kg.), was well up to the age of 21 (1925). A roentgenogram of the knee at that time showed beginning bone changes. A year later he sustained spontaneous fractures of both femurs and the right humerus. After six months of hospital treatment, he was discharged with the diagnosis of

1. Quick A. J. and Hunsberger Ambrose. Hyperparathyroidism. The Clinical Picture in the Far Advanced Stage. J. A. M. A. 86:745 (March 7) 1931.

multiple giant cell tumors. Two years later, in June 1929, he was admitted to the Philadelphia General Hospital. At this time the skeletal system was distorted and deformed, and his total length was reduced to 45 inches (83.8 cm). The pathologic changes were limited almost entirely to the osseous system, with cystic degeneration of every bone. The urine

showed a fixed specific gravity, a trace of albumin, and a high concentration of calcium. The blood calcium was consistently high (average about 15 mg per hundred cubic centimeters of blood) and the blood phosphorus low (about 3 mg). Feb 28 1930, an exploratory operation was done and a parathyroid tumor was found. Because of the operative difficulties, it is probable that not all of the tumor was removed. After three months the blood calcium was again up to 15 mg per hundred cubic centimeters. Superficial roentgen therapy was found ineffective. A second operation was done, June 5. A tumor somewhat larger than the first was found at the site of the first adenoma. Immediately

ulation alone sufficed. It was interesting that these long bones were not only angulated but actually twisted. On manipulation there was no cracking or breaking, merely a crunching, as of grinding together loose hard gravel. The leg was put in a plaster cast and the cast reapplied in May. In August the left tibia and fibula were corrected and reset.

Since the blood calcium again became abnormally high, another exploratory operation was indicated and done in March 1932. An incision was made through the old scar, and on retraction of the tissues a tumor was exposed, which was removed by blunt dissection. The tumor was irregular and lobulated and measured 3 by 2 by 1 mm. Microscopic examination of the section of the tumor showed essentially the same structure as the two previous tumors. Following the operation no serious drop in blood calcium occurred. It was 11.9 mg immediately before the operation and 8 mg the following day.

With the prospects of a permanent cure the patient was fitted with a pair of braces January 1933, and by the end of July was able with the aid of crutches to take daily walks. He was discharged from the hospital October 10. At this time the blood calcium was 10.4 mg and the roentgenographic report stated that there was a marked cystic condition of all the bones but that evidence of recalcification and new bone formation was present.

COMMENT

This case has been exceedingly instructive not only because it has demonstrated one of the most advanced stages of hyperparathyroidism but also because it has emphasized the effectiveness of treatment. It required three operations and the removal of three tumors before the blood calcium remained normal. Whether the two subsequent tumors originated from the primary adenoma or developed separately cannot be decided definitely, but it is probable the first supposition is the more likely. The case emphasizes the need for complete removal of the tumor and the advisability of a second exploratory operation if signs of hyperparathyroidism persist.

Although it is unfortunate that the disease was not arrested until such extreme deformities had occurred, there can be no question that the patient has been greatly benefited. It is doubtful whether the patient would still be living without the operations. Even in the six months at the hospital before the first operation the rapid progress of the disease was easily discernible clinically and by the increasing decalcification of all the bones. It has been possible to stop the progress of the disease and to correct somewhat the deformities. Thus, this patient, who was formerly a helpless bedridden creature, has been sufficiently restored so that he no longer requires hospital care.

Fig 1—The patient before the onset of the disease at the age of 17

after the operation a marked hypocalcemia occurred, and the patient was on the verge of tetany. This was controlled by calcium chloride and viosterol. The blood calcium became normal in eighteen days and the patient seemed apparently cured.

Fig 2—The patient three years after the onset of the disease at the age of 26

SUBSEQUENT HISTORY

Since it seemed certain that the disease had been permanently arrested efforts were made to correct some of the patient's deformities and the first operation was done in February 1931. An incision was made over the anterior surface of the right leg over the region of the greatest curvature. Although it was planned to straighten the bones by means of an osteotome it was found that this was unnecessary and that manual manip-

Fig 3—The patient three years after the final and complete removal of a parathyroid tumor. He is now able to walk with the aid of crutches.

Special Article**GLANDULAR PHYSIOLOGY AND THERAPY****THE PHYSIOLOGY AND PRINCIPAL
INTERRELATIONS OF
THE THYROID**DAVID MARINE, MD
NEW YORK

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed, the series will be published in book form.—Ed

The greatest advances in thyroid physiology during the last decade have been made in the chemistry of thyroxine¹ and in the interrelations of the thyroid with other organs both of internal and of external secretion, although in the latter field only a good beginning has as yet been made.

The fact that the principal function of the thyroid is to increase oxidative processes in the body further indicates that all body activities are influenced by the state of thyroid function and vice versa. Although the major serious disabilities due to disturbance in thyroid function are known, it is to be expected that as the interrelations are further worked out many lesser disabilities may be proved to have a definite relation to the thyroid.

In reviewing the function of the thyroid, certain general facts must be borne in mind. First, the thyroid ancestrally belongs to the alimentary tract. Second, the organ is endowed with tremendous capacities for increasing and decreasing its functional activity, as indicated by changes in weight, microscopic appearance, iodine content and blood supply. Third, hyperplasia indicates hyperactivity but not necessarily hyperfunction. Myxedema and cretinoid states may occur in individuals and animals with typical hyperplasia. It is more accurate to consider all functional hyperplasia as indicating relative or absolute iodine deficiencies and colloid goiter as the recovered, resting and physiologically normal stage.²

EFFECTS OF REMOVAL

Definite knowledge of the physiology of the thyroid may be said to have begun with Sir William Gull's report in 1874.³ He definitely connected atrophy of the thyroid, which he had observed in several middle aged women, with loss of hair, thickening and dryness of the skin, and great loss of mental and physical vigor. William Ord designated this condition as myxedema in 1878 because he thought that the thickening of the subcutaneous tissues was due to mucin formation. In 1882 the Reverdin brothers⁴ and in 1883 Theodore Kocher⁵ reported on the effects of total thyroidectomy for the cure of goiter in man, thus experimentally confirming Gull's discovery. The Reverdin brothers desig-

nated the condition they had produced as operative myxedema and Kocher as cachexia strumipriva. Following these reports many species of animals were subjected to thyroidectomy. Thyroidectomized dogs and cats usually developed parathyroid tetany, while in rabbits, sheep or goats very little obvious effects were noted, and it was not until the rediscovery of the external parathyroids in the rabbit by Gley⁶ in 1891 that a real separation of parathyroid and thyroid functions was possible. Gley's observation disproved the prevailing view that the acute symptoms which frequently followed thyroidectomy were due to thyroid removal. Since 1891 many species of animals have been subjected to thyroidectomy in which the parathyroid factor has been excluded. In 1895 Magnus-Levy,⁷ using the newly developed calorimeter, discovered that in Gull's disease the heat production was lowered as much as 40 per cent. Later a similar lowering of metabolism was found to be the characteristic effect of thyroidectomy in animals. The fall in heat production begins in most mammals between the fifth and the seventh day after thyroidectomy, in the rabbit this reaches its lowest level (from 30 to 40 per cent) between the twentieth and the thirtieth day, and in man about the sixtieth day. This low level of metabolism may be maintained for years, or as accessory thyroids or fragments regenerate the metabolism may rise, but usually not to a normal level. While qualitatively the symptoms following thyroidectomy are similar in both young and adult animals, the visible manifestations are strikingly more prominent in animals thyroidectomized during the growing period. On inspection, adult rabbits, sheep and goats may show very little change, which led the earlier workers to the belief that thyroidectomy was without much effect. Measurements of heat production in such animals, however, show the usual marked decrease. In the young this lowering of metabolism leads to stunted physical, mental and sexual development. The thyroid, therefore, appears to be not essential for vegetative life.

BIOCHEMISTRY

The next most important advance in thyroid physiology was the demonstration in 1891 by Murray⁸ of the remarkable curative effects of injections of a glycerin extract of fresh sheep thyroid in a case of Gull's disease. (This was an advanced case of five years' duration when treatment with thyroid was begun. The patient, a woman, died in 1919 at the age of 74, health having been maintained on thyroid medication for twenty-eight years⁹.) Murray's observation was quickly followed in 1892 by the independent observations of Howitz,¹⁰ Mackenzie¹¹ and Fox¹² that thyroid substance, whether fresh, dried or cooked, was equally efficacious when administered by mouth.

In 1894 Emminghaus and Reinhold¹³ showed that thyroid feeding produced a marked reduction in the size of certain types of goiter. These discoveries greatly stimulated the efforts of biochemists to isolate the active substance. Attempts to demonstrate iodine in the thyroid gland had been made many times since Comdet in 1820 first demonstrated its therapeutic value

in the treatment of goiter, but owing to faulty methods these efforts failed. The new stimulation aroused by Murray's observation prompted the work of Hutchison¹⁴ in Great Britain, Fränkel¹⁵ in Austria, Drechsel¹⁶ and Oswald¹⁷ in Switzerland and Baumann¹⁸ and his co-workers in Freiburg, which culminated in the announcement by Baumann in 1895 that iodine in a firm organic combination was a normal constituent of the mammalian thyroid. He obtained by acid hydrolysis (10 per cent sulphuric acid) a brownish powder containing as much as 93 per cent of iodine, which he named iodothyrim. Later work showed that this method destroyed most of the specific iodine compound. Baumann and his pupils showed that iodine was present in the thyroid of dogs in variable amounts and that feeding iodine increased the store. They also showed that a meat diet reduced the iodine store. Oswald¹⁹ in 1899 observed that the iodine was contained in the colloid and that the colloid was a globulin, he introduced the terms "thyroglobulin" and "iodothyroglobulin." He showed that the iodine content of the thyroid varied in general with the amount of visible colloid. The studies of Marine and Williams²⁰ and Marine and Lenhart²¹ further advanced the knowledge of the relation of iodine to thyroid structure by showing that the iodine store in general varied inversely with the degree of active hyperplasia, in extreme degrees of thyroid hyperplasia the iodine store was exhausted. At that time the opinion was widely held that iodine was excreted into the thyroid gland as part of an alleged detoxicating function. The globulin content of the thyroid is roughly the same whether the gland is hyperplastic or colloid. In the hyperplastic state the thyroglobulin is in the cells and is iodine poor, while in the colloid state the thyroglobulin is mainly in the follicles and is usually iodine rich.

The maximum iodine store in the mammalian thyroid may be raised to 5 or 6 mg per gram of dry substance. In the accompanying table the relation of the iodine store to histologic structure of several species is given.

Relation of Iodine Store to Histologic Structure

	Normal	Hyperplastic Stage			Colloid or Resting Stage
		Early	Moderate	Marked	
Man	2.17*	0.88	0.71	0.32	2.00

Sheep	2.47		0.40	0.01	3.00
Ox	3.46	1.05		0.19	
Pig	2.51	1.10			2.35

* Iodine in milligrams per gram of dried gland

The normal human thyroid weighs from 20 to 25 Gm and the maximum iodine storage is from 20 to 25 mg, while the average normal total store is from 10 to 15 mg. Fenger²² showed that iodine was normally present in the fetal thyroid, he was able to demonstrate it in the fetal calf as early as the third month. There is also a definite seasonal variation in the iodine store,

this is lower in the early spring and higher in the late summer.²³ Iodine fed to pregnant mothers is quickly stored in the fetal thyroid. Surviving thyroid *in vitro*²⁴ shows the same marked ability to take out and store iodine from the circulating fluid as is seen in the thyroid *in vivo*. So far as is known, the thyroid is the only organ capable of elaborating an iodine-containing hormone. Iodine is present in the anterior pituitary and in the ovary in significant amounts, but owing to the close physiologic relationship between anterior pituitary, ovary and thyroid its presence there could be of thyroidal origin.

Further attempts by many workers to isolate the iodine-containing hormone resulted in Kendall's²⁵ announcement in 1916 that by means of alkaline hydrolysis he had isolated a crystalline compound containing 65 per cent of iodine, which produced the same pharmacologic effects as desiccated thyroid. His attempts to determine its structure were unsuccessful. In 1926 Harington,²⁶ by improving the method of extraction from the thyroid, was able to accumulate sufficient quantities of thyroxine to determine its empirical formula as $C_{15}H_{11}O_4NI_4$ and its structural formula as 3,5,3',5' tetraiodothyronine. This work established that the mother substance of natural thyroxine is *L*-tyrosine. In 1927 Harington and Barger²⁷ synthesized this compound and showed that it had the same pharmacologic properties as natural thyroxine. Thyroxine appears to be only the active chemical group of the true hormone, which is probably iodothyroglobulin (Oswald). There are slight but definite pharmacologic differences (especially time) between thyroxine and iodothyroglobulin.

Harington also showed that the acid soluble fraction or physiologically inactive iodine noted earlier by Kendall was di-iodotyrosine. Foster²⁸ (1929) confirmed this and was able to recover 30 per cent of the total thyroid iodine as di-iodotyrosine. Harington has estimated that on an average 40 per cent of normal thyroid iodine is in the form of thyroxine and 60 per cent as di-iodotyrosine. Obviously in abnormal states of the thyroid there must be great variations in the proportions of these two compounds present, for the reason that di-iodotyrosine, though physiologically inactive, is a stage in the synthesis of thyroxine in the thyroid. The synthesis of thyroxine requires hours, while the storage of iodine in the thyroid, both *in vivo* and *in vitro*, is almost instantaneous. The form in which iodine is so quickly stored has not been determined. It is, however, firmly bound and prolonged perfusion does not wash it out if the cells are surviving (Marine and Feiss). The first evidence of thyroxine formation in the dog's thyroid, using the Gudernatsch tadpole test, was obtained by Marine and Rogoff²⁹ in about eight hours after the intravenous injection of potassium iodide.

As already mentioned, the most important single contribution to knowledge of the physiology of the thyroid was obtained by Magnus-Levy⁷ in 1895, when he demonstrated that in Gull's disease the metabolism was greatly reduced and that treatment with desiccated

thyroid raised the metabolic rate to normal or above. Magnus-Levy also discovered that the respiratory exchange in exophthalmic goiter was notably increased. Friedrich Muller³⁰ two years earlier had shown that the nitrogen metabolism was significantly increased in exophthalmic goiter. The most characteristic physiologic effects of iodothyroglobulin or its active chemical group thyroxine is that it increases, after a latent period of twelve hours or more, the oxidation in the body of proteins, fats and carbohydrates and that it also increases the excretion of certain minerals, notably calcium and magnesium.³¹ H. Zondek has shown that calcium diminishes the effect of thyroxine on tadpoles. The means by which thyroxine increases oxidative processes in the cells is unknown. Rohrer³² first showed that the oxygen consumption of minced liver, kidney and muscle of rats previously fed with thyroid substance was increased while Ahlgren³³ showed that isolated muscle from thyroidectomized animals consumed much less oxygen than normal. There is considerable evidence that epinephrine and thyroxine may work together in this process.

Gudernatsch³⁴ discovered that when small amounts of thyroid substance were fed to tadpoles there was a rapid loss in weight and metamorphosis in from four to five days. This test still remains the most sensitive test for the thyroid hormone. Other forms of iodine may hasten metamorphosis to a slight degree but never to a degree that could be confused with thyroxine action. The acetonitrile (methyl cyanide) test³⁵ depends on the protection that the thyroid hormone gives to white mice against this drug. It is not specific, since thyroid feeding decreases the resistance of rats, rabbits and guinea-pigs to acetonitrile.

The effect of thyroid administration on the heart and circulation has been studied by von Furth,³⁶ von Cyon,³⁷ Oswald³⁸ and more recently by Carter and his co-workers.³⁹ Purified solutions of iodothyroglobulin injected intravenously cause only slight lowering of blood pressure, but the heart rate is notably increased after a latent period. Oswald believes that thyroid increases the irritability of all sympathetic nerve endings. The more recent experiments of Lewis and McEachern⁴⁰ indicate that the tachycardia of thyroxine-treated rabbits continues for hours after the heart has been transferred to Ringer-Locke's solution. The relation of thyroid to antibody immunity has been extensively studied and while the results are somewhat contradictory they do not warrant any direct association of thyroid with antibody formation. However, the lowering of the iodine store and the tendency to thyroid hypertrophy in many of the infectious diseases clearly indicate that the thyroid is an important indirect factor in resistance to infections.

DIET

Diet notably affects both the structure and the chemistry of the thyroid. Baumann in 1896 and many others

have noted in dogs that fresh meats cause hypertrophy of the thyroid, while sea fish increase the iodine store and reduce the size of the gland. Watson also found that a meat diet caused hypertrophy and hyperplasia of the thyroid cells in rats. Marine and Lenhart showed that liver, particularly pig's liver, was the most potent of a great variety of meats in causing thyroid hypertrophy in dogs and cats and also that this food was an important factor in the causation of goiter in brook trout. McCarrison and later Mellanby have shown that fats also promote thyroid hypertrophy. As thyroid hyperplasia is now believed to be secondary to the depletion of the iodine store, these facts indicate that diets rich in proteins and fats increase the rate of discharge of thyroxine and suggest that thyroid activity is more necessary in the oxidation of fats and proteins than of carbohydrates. Inanition brings about involution of the thyroid, i. e., a decrease in the size of the epithelial cells, a decrease in the blood supply, and an increase in the colloid and in the iodine store—evidence of decreased functional activity.

The experiments of Baumann and Hunt⁴¹ demonstrated that the thyroid secretion is necessary for the specific dynamic action of foods. In thyroidectomized rabbits it disappears completely after about sixty-five days and can be restored in such rabbits by feeding desiccated thyroid.

INTERRELATIONS

This is both the oldest (sex glands) and the newest field of thyroid physiology, and in recent years important contributions have been made, especially as regards the relation of the thyroid to the anterior pituitary.

Thyroid-Pituitary—The major contributions in this field are those of Smith⁴² and Allen⁴³ who first devised methods of removing the pituitary in tadpoles and in rats (Smith) without injuring adjacent brain structures, and by means of these methods demonstrated that the anterior pituitary was truly a master gland in that it controlled the functional state of many organs (thyroid, sex glands, adrenals and the like).

It had long been known to students of goiter that individuals or animals with large parenchymatous goiters (Niepce,⁴⁴ Schönemann⁴⁵) have greatly enlarged anterior pituitaries. Rogowitsch⁴⁶ was the first experimentally to produce hypertrophy of the anterior pituitary by removal of the thyroid in rabbits. The pituitary hypertrophy after thyroidectomy is much greater, the younger the animal used. Doubtless many of the failures to confirm Rogowitsch's observation are due to the fact that adult animals were used. Histologically all elements of the anterior pituitary become hypertrophic, but the most striking single change is the disappearance of the eosinophil granules. Smith first noted in tadpoles and later in rats that hypophysectomy caused a marked involution of the thyroid, the injection of fresh anterior pituitary substance restored such atrophic thyroids to normal and even produced hypertrophy in these glands. Schockaert, Uhlenhuth, Loeb and many others showed that emulsions of fresh anterior pituitary acid and alkaline extracts of anterior pituitary powder in normal young susceptible animals

(adults are much less reactive and there are great species differences as well⁴⁷) causes a marked hypertrophy and hyperplasia of the thyroid, beginning within a few hours after injection. There is a rapid loss of the iodine store in the gland, there is an increase in blood iodine, in the metabolic rate, and in the excretion of calcium and creatine (Collip), and exophthalmos develops.

This thyroid stimulating substance in the anterior pituitary must be sharply distinguished from several other specific factors of the anterior pituitary which similarly stimulate body growth, the gonads, the adrenal cortex and probably many other organs as well. Loeser,⁴⁸ Anderson and Collip⁴⁹ and others have separated the specific thyroid stimulating factor from the other factors and confirmed and extended previous work. It was early observed by many workers that the daily administration of the thyrotropic factor to rats, guinea-pigs or rabbits brought about in from thirty to forty days a resistance to the thyroid stimulating factor, and the thyroid slowly regressed to its quiescent or colloid state again.^{49a} (This immunity or resistance has been demonstrated for other 'tropic' factors of the anterior pituitary as well.) Collip and Anderson⁵⁰ have shown that the serum of such recovered animals contained an antistubstance which, while not preventing the thyroid hyperplasia following the injection of the thyrotropic factor, did prevent the characteristic increase in metabolism, calcium excretion and the like. It was early pointed out that the symptoms temporarily produced in laboratory animals by injection of the thyrotropic factor were strikingly similar to those of exophthalmic goiter in man, and this suggests that possibly exophthalmic goiter occurs when the capacity to produce antihormone is impaired. Sufficient work already appears to have been done with the thyrotropic factor to justify the conclusion that the thyroid may be directly stimulated only by this anterior pituitary substance. Exhaustion of this factor is probably the immediate cause of the thyroid atrophy in some cases of Gull's disease. On the other hand the cause of endemic cretinism in animals, and probably in man as well, is primarily thyroid insufficiency since it can be cured and prevented in a single gestation by the administration of iodine.

The relation of thyroid secretion to the development of the exophthalmos of exophthalmic goiter has long been a controversial question. Prevailing opinion favored the view that it was in some way connected with hypersecretion by the thyroid. Recent work by Marine and Rosen⁵¹ has shown that such a view must be modified, since thyroidectomy notably facilitates the production of exophthalmos. At least two factors are necessary for its production: (1) a relative or absolutely deficient thyroid secretion and (2) an excess of the thyrotropic factor. This would explain why iodine administration with intact thyroid or desiccated thyroid administration after thyroidectomy prevents the occur-

rence of exophthalmos, even when large amounts of the thyrotropic factor are administered. This would also explain why thyroid insufficiency alone, as in Gull's disease, is usually not associated with exophthalmos, because the thyroid atrophy in this disease appears to be primarily dependent on an insufficiency of the thyrotropic factor. Recently we have found a great diminution in the thyroid stimulating factor of the anterior pituitary from a patient with Gull's disease. The thyrotropic factor of the anterior pituitary stimulates thyroid transplants in any part of the body to approximately the same degree that the nontransplanted thyroid is stimulated. Recently Eitel, Krebs and Loeser⁵² have demonstrated that the thyrotropic factor stimulates surviving thyroid cells in vitro. Such studies further confirm the view that the thyrotropic factor acts directly on the gland cells and that specific or intact nerve connections are unnecessary, either for secretory or for excretory activity of the gland.⁵³ The pituitary influence also probably explains why normally the growth of thyroid transplants or the degree of thyroid regeneration is in proportion to the amount of thyroid removed.

Thyroid-Sex Glands—This interrelationship has been recognized for centuries because of the enlargement of the thyroid during menstruation and pregnancy and the increased frequency of goiter during puberty, pregnancy and the menopause. It is known that the ovary and hypophysis stand next to the thyroid as regards iodine store. The nature of this relationship is still uncertain, but the recent work with the pituitary suggests that this organ is the necessary intermediate. Total removal of the sex glands in the dog, rabbit and rat usually leads to a slow involution of the thyroid in about one month and to slight reduction of total metabolism, indicating a depression of thyroid function. Several observers have reported a slight hypertrophy immediately after gonadectomy. Abelin⁵⁴ and others have shown that thyroid feeding has an inhibitory effect on estrus. Da Costa and Carlson⁵⁵ found that desiccated thyroid in large doses retarded sexual maturation of white rats of both sexes while small doses of thyroid tended to accelerate it. Schockaert⁵⁶ noted that emulsions of anterior hypophysis caused a greater hypertrophy of the accessory male sex glands after thyroidectomy than before. Many observers have noted that the prolonged injection of estrogenic substance causes a flattening of the thyroid epithelium and an increase in colloid, a few have reported opposite effects. The more recent observations of Pincus and Werthessen⁵⁷ and of Tagliaferro⁵⁸ may correlate these conflicting results. The latter found that thyroid enlargement occurred in rats and guinea-pigs following injections of estrogenic substance continued for five or ten days, whereas when the injections were continued for twenty days or more the opposite effect (involution) was observed.

It appears that the effects of the thyroid on the gonads and vice versa could be explained as effects

49a This discovery makes it necessary to distinguish between activators and true internal secretions. Since Bayliss and Starling first applied the term hormone to one of these activators, secretin, it would be logical to reserve the term for those factors which excite various organs to increased secretion of their specific products and against which the body produces antihormones.

mediated through the anterior pituitary. There is abundant evidence that the response of the pituitary to thyroidectomy is not limited to stimulating an increased production of the thyrotropic hormone but that there is an increase in the growth hormone and the gonadotropic factors as well, vice versa, a depression of the thyrotropic factor by the administration of thyroxine probably depresses the gonadotropic factor. In rabbits that have been thyroidectomized at puberty (4 to 5 months) there is frequently noted an increase in sexual activity. So also injecting large doses of estrogenic substance appears to decrease the amount of gonadotropic factor produced by the pituitary as well as depressing the thyroid glands. These effects are understandable if one assumes that the same pituitary cell produces more than one hormonal factor, there is evidence that the eosinophilic cells may be responsible for the secretion of the thyrotropic and growth promoting factors.

Thyroid-Thymus—Gudernatsch⁵⁴ noted that thymus feeding greatly delayed the onset of metamorphosis in tadpoles and that it offered some protection against thyroid feeding. Hoskins⁵⁹ obtained an increase in weight of the thymus at birth in guinea-pigs whose mothers were fed desiccated thyroid. Thyroidectomy definitely hastens thymus involution⁶⁰. Feeding desiccated thyroid causes regeneration of such atrophic thymuses. In conditions in which thyroid activity is increased, as in exophthalmic goiter and acromegaly, there is usually thymus hypertrophy. These effects could be interpreted as indicating some kind of antagonism between the thyroid and the thymus.

Thyroid-Pancreas—Falta⁶¹ (1905) thought that the thyroid and pancreas were antagonistic. He found that thyroidectomized dogs were less sensitive to the hyperglycemic action of epinephrine than normal animals. This has been confirmed by Bodansky⁶² (1923) and by Burn and Marks⁶³ (1925). Bodansky reported that thyroidectomized sheep were more sensitive to insulin than normal animals. This observation has been generally confirmed. Conversely, it has been shown that feeding thyroid or thyroxine to thyroidectomized rabbits decreases the hypoglycemic action of insulin. Bodansky believes that the thyroid hormone promotes glycogenolysis and that it is because of this action that the hypoglycemic action of insulin is increased after thyroidectomy and decreased by thyroid feeding. The effect of thyroid feeding probably is due in part to its sensitizing effect on epinephrine stimulation of the sympathetic nervous system.

Thyroid-Liver—Liver injury in exophthalmic goiter (mild, moderate and severe fibrosis, depletion of glycogen and, in severe cases, focal necrosis, jaundice and subacute yellow atrophy), although long known, has attracted more attention of late. Gerlei⁶⁴ obtained some confirmatory evidence of this sequence experimentally in the rabbit. He found that the injection of 4 mg of thyroxine daily (rabbits are very susceptible to the action of thyroxine) usually led to death in from five to seven days. These animals showed severe degenera-

tive lesions in the liver, beginning with cell necrosis in the central portion of the lobule and extending peripherally and involving the whole lobule. With the fusion of these lobular necroses large areas may be affected, and this condition may resemble acute yellow atrophy. Experimentally it has been abundantly confirmed that prolonged excessive thyroid feeding greatly reduces the glycogen store in the liver. This depletion of glycogen appears to depend on its increased utilization rather than on any immediate impairment of storage capacity by the liver. Conversely, thyroidectomy increases the glycogen storage in rabbit liver leading to a characteristic nutmeg appearance. Epinephrine probably is a necessary adjunct in the increased mobilization of glycogen in hyperthyroid states.

Thyroid-Chromaffin System—Epinephrine markedly constricts the thyroid veins following its intravenous injection⁶⁵. Eppinger, Falta and Rudinger⁶⁶ first suggested an interrelationship. They assumed that epinephrine directly stimulated the thyroid gland. In 1911 Asher and Flack⁶⁷ showed that the blood pressure response in rabbits to a given dose of epinephrine was greater after stimulation of the thyroid nerves with intact thyroid than before. This has received confirmation from several sources, particularly by Cannon and his co-workers. Oswald⁶⁸ has shown that a similar increase in the blood pressure response to epinephrine may be obtained by the intravenous injection of iodothyroglobulin and that the effect is proportional to the iodine content of the thyroglobulin. Blau and McNamara⁶⁹ obtained the same effect by using thyroxine, Bergwall and Kuschinsky⁷⁰ obtained this effect with thyroxine after adrenalectomy. The Goetsch epinephrine test in exophthalmic goiter is a clinical application of this increased sensitiveness to epinephrine. All these observations would support the original view of Asher and Flack that the thyroid hormone increases the irritability of the sympathetic nervous system or sensitizes in some way the tissues innervated by it, so that they are more susceptible to stimulation by epinephrine. On the other hand, Zunz and La Barre⁷¹ have reported that injections of from 1 to 3 mg of thyroxine in dogs caused a gradual hyperglycemia in the course of from three to six hours and that this did not occur when the adrenal veins were ligated just prior to the injection of thyroxine. These observations would suggest a direct stimulation of the chromaffin system by thyroxine.

Thyroid-Adrenal Cortex—Golyakowski⁷² observed an increased output of carbon dioxide in dogs following the mass ligation of most of the adrenal vessels. Marine and Baumann⁷³, working with rabbits, reported a definite increase in heat production in thirty-one out of thirty-nine rabbits from which both adrenal glands were partially removed, and in six out of fifteen rabbits whose adrenal function had been crippled by freezing.

the glands. This increase in heat production usually began between the third and the sixth day following adrenal injury and lasted from a few days to a month or more. In a few cases heat production was increased more than 60 per cent above normal. It was felt that infection and trauma could be excluded. If, however, the thyroid gland was removed and the metabolism allowed to fall to the myxedema level prior to the injury of the adrenal glands, this increase in heat production did not occur. Scott⁷⁴ obtained a few instances of increased heat production in cats with injured adrenals, but it was difficult to get sufficient but sublethal injury of the adrenal in this animal. Davis and Hastings⁷⁵ have recently shown that adrenalectomized mice, after a latent period of about forty days, show an increased total metabolism and an increase in the metabolism of excised abdominal muscle as well. They also confirm the observations of Marine and Baumann that a previous thyroidectomy prevents this rise in metabolism. The most logical interpretation of these results is that the adrenal cortex (and the sex glands), acting through the anterior pituitary, normally exercise some regulatory or inhibitory control over thyroid function, when this control is sufficiently depressed or withdrawn, the activity of the thyroid is temporarily increased. The only substance yet known common to both adrenal cortex and sex glands that appears capable of depressing the thyroid function by way of the pituitary is estrogenic substance, and this possibility is being further investigated.

It should also be pointed out that there is some evidence that the adrenal cortex exercises an inhibitory control over other organ functions as well as the thyroid, for example, the increased sexual activity and priapism that commonly occurs in rabbits and rats a few days after adrenalectomy.

In this connection also the normal involutionary destruction of the reticular and fascicular zones of the adrenal cortex in infants beginning about the eighth day after birth should be mentioned.⁷⁶

The demonstration by Smith that a somewhat similar lesion regularly occurs in the adrenal cortex after hypophysectomy and the demonstration by Collip, Anderson and Thomson⁷⁷ of a specific adrenotropic factor in the anterior pituitary suggest that this normal adrenal involution in infants is due to the withdrawal of the maternal adrenotropic factor. The physiologic significance of the relatively large adrenal cortex of human fetuses and its partial destruction beginning in the second week after birth is unknown. It has, however, been established that coincident with this destructive lesion of the cortex there is an increase in heat production,⁷⁸ and it is possible that it may have the same physiologic significance as the increased heat production in rabbits, cats, rats and mice following experimental injury or removal of the adrenal cortex.

Thyroid-Kidney (Diuresis).—During the last forty years, clinicians have frequently reported improved water elimination in certain forms of nephritis by the

administration of desiccated thyroid and more recently of thyroxine, alone or combined with parathyroid extract. This form of therapy has been used particularly in the so-called lipoid nephrosis. No explanation for the effects noted has been forthcoming beyond the possibility that these drugs increased the mobilization and excretion of calcium.

The recent revival of work on the pituitary gland has brought out other facts, which also suggest that the thyroid is involved in water excretion through the kidney. Transient polyuria was almost constantly obtained by the earlier workers using the transdural method of approaching the hypophysis. It was found that sectioning of the stalk alone, trauma of the adjacent hypothalamus and particularly injuries in the region of the supra-opticus nuclei led to polyuria.

Teel⁷⁹ first noted polyuria in dogs given daily injections of an alkaline extract of fresh anterior pituitary. Polyuria and glycosuria lasting a week or two has been obtained by many workers in dogs, rabbits and rats injected with salt solution emulsions or with alkaline and acid extracts of the anterior pituitary.

Barnes, Regan and Bueno⁸⁰ noted polyuria in dogs following the injection of extracts of anterior pituitary, beginning usually on the second day and returning to normal in ten days. In thyroidectomized dogs this polyuria did not occur. Biasotti⁸¹ confirmed both these observations and added that castration or section of the splanchnics did not affect the polyuria. He also confirmed the increased urinary output in normal dogs following the administration of very large doses of desiccated thyroid. During the past four years, Rosen and I⁸² have studied several instances of polyuria in rabbits which developed in connection with our experiments on goiter produced by cyanide and alfalfa hay. All the instances observed were in young male adults with large goiters, and the polyuria began within two days after starting small doses of potassium iodide (125 mg, three times weekly). All goitrous rabbits thus treated, as first shown by Webster and Chesney,⁸³ develop an intense hyperthyroidism (sometimes fatal) with great loss of weight. In one instance in which potassium iodide was given, the polyuria persisted for three months, at which time a thyroidectomy was performed. The polyuria (as high as 800 cc daily) gradually receded to a daily average of 50 cc during the next ten days and remained down for several weeks, although the rabbit was receiving potassium iodide (125 mg, three times weekly). Desiccated thyroid was started in doses of 0.1 Gm, three times weekly, and the polyuria recurred on the second day of the treatment. In none of these cases has the polyuria been associated with glycosuria as is the case when anterior pituitary extracts are used. Desiccated thyroid or iodine in twice these amounts has not appreciably increased the urine output in my nongoitrous, thyroid intact rabbits. Normal rabbits subjected to thyroidectomy are more sensitive to thyroid feeding than rabbits with intact thyroids, but this increased sensitivity is slight in comparison to that of rabbits that had goiter prior to thyroidectomy.

PAUL NICHOLAS LEECH, Secretary

BETA-LACTOSE — $C_{12}H_{22}O_{11}$ — A disaccharide obtained by allowing a solution of lactose to crystallize above 93 C.

Actions and Uses—Like its more common isomer, lactose-U S P, beta-lactose is used as a diluent and as a food, particularly in modified milk for infants, also as a supplementary food for adults. However, it possesses greater solubility and a higher degree of sweetness than lactose-U S P. Beta-lactose provides a favorable medium for the growth of the *B. acidophilus*.

Dosage—The same as for lactose-U S P.

Manufactured by the National Milk Sugar Co. Inc. New York U. S. patent 1956811 (May 1 1934 expires 1951).

Beta lactose occurs as small odorless white rhombic crystals. It is freely soluble in either hot or cold water but alpha lactose is liable to separate when strong solutions are allowed to stand. It is almost insoluble in alcohol and definitely insoluble in ether and chloroform.

The specific rotation $[\alpha]_D^{25}$ of a 10 per cent solution at 25 C. measured not more than three minutes after the water is first added to the substance ranges between +35 and +38. After standing twenty four hours, the specific rotation $[\alpha]_D^{25}$ ranges between 52.5 and 55.5.

Add an equal volume of sodium hydroxide solution to a hot 20 per cent solution of beta lactose and warm the mixture; the liquid turns yellow and finally brownish red on subsequent addition of a few drops of cupric sulphate solution a precipitate of cuprous oxide occurs. Add to 5 Gm. of beta lactose sufficient water to make 25 cc. of solution; the solid dissolves in less than five minutes.

Dissolve 3 Gm. of beta lactose in 10 cc. of boiling distilled water; the solution is clear, colorless, odorless and neutral to litmus paper.

Transfer 1 Gm. of beta lactose to an Erlenmeyer flask and boil for ten minutes with 15 cc. of alcohol under a reflux condenser; allow to stand five hours or longer at room temperature; filter; evaporate 10 cc. of the filtrate to dryness on the steam bath; the residue weighs not more than 0.007 Gm. (sucrose dextrose).

A 5 per cent aqueous solution of beta lactose meets the U. S. P. X. requirements for heavy metals (U. S. P. X. p. 439).

Dissolve 1 Gm. of beta lactose in 50 cc. of distilled water; boil for one minute; cool, add a drop of iodine solution; the solution is not colored red, green or blue (starch, dextrin).

Transfer about 2 Gm. of beta lactose accurately weighed in a wide mouth weighing bottle to a desiccator containing a 60 per cent solution of calcium nitrate; when constant weight is obtained transfer to an oven at 70 C. until constant weight is again attained; finally transfer to a vacuum oven at 100 C. and a pressure of 2 cm. of mercury until constant weight is attained. The loss obtained by use of the vacuum oven is not more than 0.18 per cent.

NOVOCAIN (See New and Nonofficial Remedies, 1935, p. 63)

The following dosage forms have been accepted:

Ampules Sterile Crystals Novocain for Spinal Anesthesia 50 mg
Ampules Sterile Crystals Novocain for Spinal Anesthesia 100 mg
Ampules Sterile Crystals Novocain for Spinal Anesthesia 120 mg
Ampules Sterile Crystals Novocain for Spinal Anesthesia 150 mg
Ampules Sterile Crystals Novocain for Spinal Anesthesia 200 mg
Ampules Sterile Solution Novocain 20 per cent 15 cc. This solution must be diluted before it is used.

Ampules Sterile Solution Novocain 20 per cent 5 cc. This solution must be diluted before it is used.

Ampules Sterile Solution Novocain 20 per cent with 1 Suprarenin Synthetic Bitartrate 1 9000 15 cc. Novocain 0.3 Gm. and 1-suprarenin synthetic bitartrate 0.165 mg. in distilled water to make 15 cc. This solution must be diluted before it is used.

Ampules Sterile Solution Novocain 20 per cent with 1 Suprarenin Synthetic Bitartrate 1 9000 5 cc. Novocain 1 Gm. and 1-suprarenin synthetic bitartrate 0.55 mg. in distilled water to make 5 cc. This solution must be diluted before it is used.

Ampules Novocain Solution 1 per cent 2 cc. Novocain 0.02 Gm. sodium chloride 0.12 Gm. in distilled water to make 2 cc.

Ampules Novocain Solution 1 per cent with 1 Suprarenin Synthetic Bitartrate 1 5000 2 cc. Novocain 0.02 Gm. 1-suprarenin synthetic bitartrate 0.04 mg. sodium chloride 0.009 Gm. potassium sulphate 0.008 Gm. in distilled water to make 2 cc.

Ampules Novocain Solution 1 per cent with 1 Suprarenin Synthetic Bitartrate 1 5000 6 cc. Novocain 0.06 Gm. 1-suprarenin synthetic bitartrate 0.12 mg. sodium chloride 0.027 Gm. potassium sulphate 0.024 Gm. in distilled water to make 6 cc.

Ampules Novocain Solution 2 per cent with 1 Suprarenin Synthetic Bitartrate 1 5000 1 cc. Novocain 0.02 Gm. 1-suprarenin synthetic bitartrate 0.02 mg. in distilled water to make 1 cc.

Ampules Novocain Solution 2 per cent with 1 Suprarenin Synthetic Bitartrate 1 20000 1 cc. Novocain 0.02 Gm. 1-suprarenin synthetic bitartrate 0.05 mg. in distilled water to make 1 cc.

Ampules Novocain Solution 2 per cent with 1 Suprarenin Synthetic Bitartrate 1 50000 3 cc. Novocain 0.06 Gm. 1-suprarenin synthetic bitartrate 0.06 mg. sodium chloride 0.0135 Gm. potassium sulphate 0.012 Gm. in distilled water to make 3 cc.

Ampules Novocain Solution 2 per cent with 1 Suprarenin Synthetic Bitartrate 1 20000 3 cc. Novocain 0.06 Gm. 1-suprarenin synthetic bitartrate 0.15 mg. sodium chloride 0.0135 Gm. potassium sulphate 0.012 Gm. in distilled water to make 3 cc.

Ampules Novocain Solution 2 per cent with 1 Suprarenin Synthetic Bitartrate 1 20000, 6 cc. Novocain 0.12 Gm. 1-suprarenin synthetic bitartrate 0.3 mg. in distilled water to make 6 cc.

Ampules Ephedrine Novocain Solution 1 cc. Novocain 1 per cent and ephedrine hydrochloride N N R 5 per cent.

Ampules Ephedrine Novocain Solution 2 cc. Novocain 1 per cent and ephedrine hydrochloride N N R 5 per cent.

Tablets Novocain 1 grain
Novocain (0.08 Gm.) and 1 Suprarenin Synthetic Bitartrate (0.06 mg.)

Hypodermic Tablets Novocain 0.08 Gm. and 1-suprarenin synthetic bitartrate 0.06 mg.

Tablets Novocain 0.01 Gm. with 1 Suprarenin Synthetic Bitartrate 0.2 mg.

EPHEDRINE HEMIHYDRATE (See THE JOURNAL, May 11, 1935, p. 1707)

Ephedrine Alkaloid-Merck—A brand of ephedrine hemihydrate-N N R.

Manufactured by Merck & Co. Inc. Rahway N. J. No U. S. patent or trademark.

EPHEDRINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1935 p. 201)

Ephedrine Hydrochloride-Merck—A brand of ephedrine hydrochloride-N N R.

Manufactured by Merck & Co. Inc. Rahway N. J. No U. S. patent or trademark.

EPHEDRINE SULPHATE (See New and Nonofficial Remedies, 1935 p. 202)

Ephedrine Sulphate-Merck—A brand of ephedrine sulphate-N N R.

Manufactured by Merck & Co. Inc. Rahway N. J. No U. S. patent or trademark.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH, Secretary

SCOTT'S EMULSION OF COD LIVER OIL OMITTED FROM N N R AND SCOTT'S COD LIVER OIL CONCENTRATE TABLETS UNACCEPTABLE FOR N N R

Scott's Emulsion of Cod Liver Oil (formerly marketed under the noninformative name "Scott's Emulsion") was accepted in 1932 for inclusion in New and Nonofficial Remedies as a dosage form of Scott's Norwegian Cod Liver Oil (Plain). As a condition of acceptance, Scott & Bowne adopted the more informative name, eliminated the therapeutically worthless calcium and sodium hypophosphites from the formula, and eliminated therapeutic claims for these constituents from the advertising. As accepted by the Council, the statement of composition was:

Scott's emulsion of cod liver oil is prepared from Scott's Norwegian cod liver oil (plain) 27.9 per cent (30 per cent by volume) glycerin 12.5 per cent acacia 1.56 per cent tragacanth 1.46 per cent flavoring 0.15 per cent agar 0.03 per cent and water to make 100 per cent.

In 1933 the firm informed the Council that complaints were being received that the product as prepared under the new formula was not satisfactory; the absence of the hypophosphites causing the emulsion to be less stable. The firm was granted permission to replace the hypophosphites as a pharmaceutical measure on condition that no therapeutic claims were made on the basis of their presence. The firm agreed to this and the formula was changed to:

Cod Liver Oil	27.90% by weight
Glycerine	12.50%
Gum Arabic	1.56%
Gum Tragacanth	1.46%
Essential Oils (flavoring)	16%
Calcium Hypophosphite	78%
Sodium Hypophosphite	39%
Agar Agar	07%
Distilled Water	55.18%
	100.00%

Meanwhile Scott & Bowne had presented its Cod Liver Oil Concentrate Tablets for the Council's consideration. This product was found acceptable provided certain changes were made in the trade packages and provided evidence should be presented to support the claim that the tablets are "protected against deterioration."

Recently the firm informed the Council that the Department of Agriculture had ruled the name "Scott's Emulsion of Cod Liver Oil" not permissible, since the product has not the composition of the official emulsion of cod liver oil. Thus being under the necessity of changing either the name or the composition of the product, the firm informed the Council that it felt obliged to return to the old name, "Scott's Emulsion," retaining the present composition. The firm informed the Council that the department had stated that the name "Scott's Emulsion" would not infringe on any of its regulations. The uninformative name is, of course, contrary to the Council's rule. The firm, however, would make no other change, although it was informed of a communication to the Council from a representative of the department to the effect that a name such as "Scott's Emulsion of 30% Cod Liver Oil" would be equally acceptable.

The firm informed the Council that its Cod Liver Oil Concentrate Tablets were to be advertised in connection with the emulsion and has taken no steps to make the product otherwise acceptable.

The Council was therefore obliged to omit Scott's Emulsion of Cod Liver Oil (now "Scott's Emulsion") from New and Nonofficial Remedies and to declare Scott's Cod Liver Oil Concentrate Tablets unacceptable for New and Nonofficial Remedies.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

- 1 HOVDEN'S STEAM GRILLED SARDINES IN OLIVE OIL AND TOMATO SAUCE
- 2 HOVDEN'S CALIFORNIA SARDINES BONELESS PEELED PACKED IN OLIVE OIL
- 3 HOVDEN'S CALIFORNIA SARDINES FRENCH STYLE PACKED IN OLIVE OIL
- 4 HOVDEN'S CALIFORNIA SARDINES GARNISHED PACKED IN OLIVE OIL
- 5 HOVDEN'S CALIFORNIA SARDINES FILETS SMOKED BONELESS PACKED IN OLIVE OIL
- 6 PREFET BONELESS PEELED SARDINES IN OLIVE OIL
- 7 PREFET FRENCH STYLE SARDINES PACKED IN OLIVE OIL
- 8 PREFET GARNISHED SARDINES IN OLIVE OIL
- 9 PREFET FANCY FILET OF SARDINES SMOKED BONELESS IN OLIVE OIL
- 10 PREFET CALIFORNIA SARDINES PACKED IN OLIVE OIL AND TOMATO SAUCE
- 11 PREFET CALIFORNIA SARDINES PACKED IN OLIVE OIL AND MUSTARD SAUCE

Packer—K. Hovden Company, Monterey Calif

Distributor of Prefet Brands—Pacific Packers Association, Monterey, Calif (subsidiary of K. Hovden Company)

Description—(1) and (10) Canned steam grilled sardines (*Clupea caeruleus*, blue sardines) with tomato sauce, salt and olive oil, the same as Portola Sardines (Pilchards) Steam Grilled—In Tomato Sauce and Olive Oil (THE JOURNAL, June 4, 1932, p 1991)

(2) and (6) Cooked, peeled and boneless Pilchard sardines packed in olive oil in tins, the same as Boneless Peeled Portola Sardines (In Olive Oil) (THE JOURNAL, June 18, 1932, p 2211)

(3) and (7) Cooked immature sardines packed in olive oil, the same as Portola French Style Sardines (In Olive Oil) (THE JOURNAL, July 9, 1932, p 135)

(4) and (8) Cooked immature sardines packed in olive oil with slices of pickle, carrot and pimiento, in tins, the same as Portola Garnished Sardines (In Olive Oil) (THE JOURNAL, July 16 1932, p 225)

(5) and (9) Cooked, boneless smoked Pilchard sardines packed in olive oil in tins, the same as Portola Filet of Sardines (In Olive Oil) (THE JOURNAL, July 2, 1932, p 35)

(11) Same as (1) except that mustard sauce replaces tomato sauce

PURINA WHOLE WHEAT BREAD

Distributor—National Tea Company, Chicago

Description—A whole wheat bread made by the straight dough method (method described in THE JOURNAL, March 12, 1932, p 889), prepared from whole wheat flour, water, vegetable shortening, honey, corn sugar, yeast, salt and malt extract

Analysis (submitted by distributor)—

	per cent
Moisture	36.3
Ash	2.0
Fat (ether extraction method)	6.1
Protein (N \times 6.25)	9.9
Crude fiber	1.5
Carbohydrates other than crude fiber (by difference)	44.2

Calories—2.7 per gram 77 per ounce

Claims of Distributor—Conforms to the United States Department of Agriculture definition and standard for whole wheat bread

CELLU YELLOW CLING PEACHES PACKED IN WATER WITHOUT ADDED SUGAR OR SALT

Distributor—The Chicago Dietetic Supply House, Inc, Chicago

Packer—Hunt Brothers Packing Company, San Francisco

Description—Canned cooked pitted yellow cling peach halves, packed in water without added sugar or salt

Manufacture—The method of manufacture is essentially the same as for Cellu Juice-Pak Cling Peaches (THE JOURNAL, Aug 25, 1934, page 564), with the exception that the fruit is packed in water

Analysis (submitted by distributor)—

	per cent
Moisture	92.9
Total solids	7.1
Ash	0.3
Fat (ether extract)	0.1
Protein (N \times 6.25)	0.2
Reducing sugars as invert sugar	2.5
Sucrose	2.5
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	6.3

Calories—0.3 per gram 9 per ounce.

Claims of Distributor—For diets in which sweetened fruit is proscribed

CUBE FLAVORED JELL-WELL GELATINE DESSERT CONCORD GRAPE FLAVOR

Manufacturer—Jell-Well Dessert Company, Los Angeles

Description—Gelatin dessert mixture sucrose, gelatin, tartaric acid, salt, cream of tartar, U S Department of Agriculture certified color and Concord grape concentrate. The flavor is sealed in cubes of sugar

Manufacture—Sugar, gelatin, tartaric acid, cream of tartar and salt are mixed and automatically weighed into packages along with two cubes prepared by mixing sugar and grape concentrate. The cubes are coated with crystallized sugar to prevent loss of volatile flavor

Analysis—See Jell-Well Gelatine Desserts (THE JOURNAL, Dec 31, 1932, p 2266)

Calories—3.8 per gram, 108 per ounce.

SATURDAY, JUNE 22, 1935

THE 1935 ANNUAL SESSION

The annual session of the American Medical Association held in Atlantic City last week shattered all records for medical meetings held anywhere in the world. The registration, numbering 8,469, included more physicians than have ever before been assembled for a convention at one time. The exhibits, both technical and scientific, were larger and covered a greater variety of medical topics than have ever previously been shown in any exhibits of similar character. The House of Delegates functioned with extraordinary dispatch and revealed even to the uninformed observer the unanimity of the medical profession in its point of view regarding social tendencies affecting medical practice. Unquestionably the Atlantic City session will go down in history as one of the most successful ever held and will mark a new peak at which future sessions may aim.

The meeting began on Monday, June 10, in the midst of a downpour, which it is understood marked a record in precipitation of water for the New Jersey coast. Yet this flood was no deterrent to the attendance, since the number of physicians registering on the first day was the greatest ever recorded for the first day of any medical meeting. No doubt the downpour served a useful purpose in causing the vast majority of those who registered to spend their full time in the great Atlantic City auditorium, which again, in the vast expanse of its floor space and meeting places, overwhelms that of other auditoriums in the country.

On Monday noon the official bodies of the Canadian Medical Association tendered a luncheon to the Board of Trustees and officers of the American Medical Association, at which a gavel was presented to the American organization. This gavel, of unique appearance and history, will be described in forthcoming accounts of the annual session. The golf tournament scheduled for Monday was necessarily postponed until Tuesday.

On Monday afternoon and throughout Tuesday the general scientific meetings attracted thousands of physicians, who received during this time a postgraduate

education in many special subjects given by lecturers who had been especially selected by the Council on Scientific Assembly for this purpose.

On Monday night the New Jersey medical profession tendered a dinner and entertainment to the House of Delegates and officers of the Association. At this dinner, Senator James Hamilton Lewis, who had come to Atlantic City to confer with officers of the Association, spoke inspiringly for world peace and emphasized the great importance of the medical profession in molding public opinion. Indeed, he said to the profession that its members might well determine the policy of the nation on any subject to which they gave their earnest thought and effort.

The opening general meeting on Tuesday night included an attendance of more than seven thousand, and it is estimated by Atlantic City physicians that from two to three thousand additional persons were unable to gain admission to the hall. At this extraordinary meeting, an address was spoken by former senator and ambassador Walter Edge, welcoming addresses were made by the mayor of the city and representatives of the New Jersey profession, and the presidential addresses were delivered by Drs. Meakins and McLester. The last mentioned addresses likewise appear in this issue of THE JOURNAL. The mayor of Atlantic City tendered a gold emblem to the Association as a permanent token of invitation. The music for this occasion was provided by the Westminster Chorus of Princeton, N. J., and although the meeting lasted well beyond 11 o'clock the audience insisted on numerous encores, so that midnight approached before the meeting adjourned.

On Wednesday, Thursday and Friday vast numbers of physicians continued to pour into Atlantic City, coming by motor car, by rail, by airplane and by every other method of transportation to accumulate the attendance to which reference has already been made. An analysis of this attendance will be published presently in connection with the report of the meetings of the House of Delegates.

The elections in the House of Delegates were spirited and indicated that the delegates had given most serious consideration to the issues involved in determining their choice. On Thursday night the President's reception, tendered to the presidents of the American and Canadian medical associations, attracted a vast multitude of physicians and congested all the available space for dancing and entertainment in the headquarters hotel.

The press of the United States sent representatives especially for this session, so that the publicity reached throughout the world. Moreover, radio broadcasting systems made available the time for lectures as well as for news reports from this session.

An unusual feature was the attendance as a guest of Dr. Allan Roy Dafoe, he was most courteous in visiting various meetings and created a veritable sensation

by his appearance at the annual luncheon of the Woman's Auxiliary. The Woman's Auxiliary likewise had one of the most successful assemblages in its history. Atlantic City offers unusual opportunities for entertainment and for vacation. For this reason, great numbers of those visiting the annual session brought their wives and children. No doubt many a young boy and girl received at this annual session impressions that will lead to a choice of medicine as a profession in the coming years.

The annual session of 1935 closed on a note of quite general satisfaction. It served to bring together more closely the medical professions of two great neighboring nations. It helped to inform the medical profession and the public generally that the physicians of the United States still feel that they themselves must determine the nature and the methods of medical practice. It emphasized again the earnest desire of the medical profession to provide adequate medical care for all the people. It is hoped that physicians throughout the nation who were unable to participate in this great gathering will read most carefully the detailed reports which appear in this and future issues of *THE JOURNAL*.

The physicians of New Jersey and especially of Atlantic City were assiduous in their attention, courteous in all their contacts, and gracious and hospitable to all their guests. The thanks and appreciation of the American Medical Association are tendered to all those who gave of their utmost to contribute to the great success of this occasion.

THE BIOLOGIC IMPORTANCE OF PRESSURE

One of the fundamental requirements of all living organisms is the ability of constant adaptation to physical changes in the environment. Alterations in environmental temperature and humidity are most commonly considered in this connection, the compensatory mechanisms for variations in these factors have been extensively investigated. There are other environmental factors, however, that may exert a profound influence. Of these, one of the most interesting but apparently least studied is the effect of pressure.

Adaptation to variations in pressure presents a real problem to many different forms of life. Fish, for example, are exposed to a pressure of two atmospheres at a depth of only 34 feet below the surface of the water. The pressure at a depth of 2 miles, at which various species of fish have been captured, is approximately 300 atmospheres, or 4,600 pounds per square inch. Apparently, one of the chief compensatory adjustments required is an alteration in specific gravity, so that the fish may swim about without the expenditure of too great an amount of energy. This is accomplished by variations in the volume of the swim bladder, mere expansion or contraction serving to compensate for

minor changes in pressure, whereas active absorption or secretion of gases is probably called into play where depth changes of a greater magnitude occur. Under certain conditions man may be exposed to significant alterations in pressure. Aviators and mountain climbers may encounter marked decreases, the pressure at an elevation of 18,000 feet being only one-half that at sea level. Small decreases in pressure occurring in changes in altitude of a few hundred feet produce well known sensations in the ears, greater decreases may cause "mountain sickness," a condition resulting from the lowering of oxygen tension. The compensatory response of the organism against the latter is splenic contraction, with the forcing into the blood stream of more erythrocytes to aid in oxygen transport to the tissues, subsequently, new erythrocytes are released into the circulation in increased numbers by the bone marrow. Increases in environmental pressure, encountered by deep sea divers and caisson workers, are apparently well tolerated. The danger comes with the return of the subject to atmospheric pressure. It is necessary to exercise great caution in order to avoid too abrupt a decrease in pressure, which might cause the sudden release of nitrogen gas from solution into the tissues, where it causes serious symptoms known as the "bends" or caisson disease.

A number of experimental studies have been conducted to determine the effects of alterations of environmental pressure on laboratory animals or on isolated tissues. Recently¹ the behavior of muscle and nerve tissue at increased pressures has been observed. An ingenious chamber was devised, which permitted observations on the tissue while exposed to pressures as great as 15,000 pounds per square inch (approximately 100 atmospheres). Observations on cardiac muscle showed that an increase in pressure to approximately 100 times normal produced a marked increase in the degree of shortening of the muscle following stimulation. Further increases up to 6,000 pounds per square inch produced similar stepwise increases in the force exerted by the contracting muscle up to four times the control value. This effect was completely reversible, as the response returned to its original character as soon as the pressure was released. Simultaneous measurements of heat production and the actual work done during the contraction showed that a parallel increase in the two occurred, thus demonstrating that an increase in pressure did not augment the efficiency of the mechanism whereby chemical energy is converted into mechanical work. Similar pressure effects were observed with skeletal muscle, however, the magnitude of the heightened degree of contraction with increases in pressure was less. At higher pressures the augmenting effect of increased pressure disappeared, indeed, the response of skeletal muscle became even less than at atmospheric pressure. This observation is not surprising in view

¹ Cattell, McKee. The Biological Importance of Pressure. *Scient. Monthly*, 40: 468 (May) 1935.

of the alleged effect of extremely high pressures on proteins. The statement has been made that pressures of 88,000 pounds per square inch coagulate muscle protein or egg white irreversibly at room temperature.

The effects of increased pressure on nerves paralleled in general those obtained on muscle. Moderate pressures exerted a stimulatory effect, lowering the threshold of excitation and increasing the velocity of propagation. High pressures produced the opposite effect. Entirely different results were obtained, however, when even small pressures were applied locally to the nerve. A rapid loss of function ensued. The common experience of having a limb "go to sleep" following the prolonged application of a small local pressure may be explained on the basis of the foregoing experiment.

IODINE AND ATHEROSCLEROSIS

The production of atherosclerosis in rabbits by the administration of considerable quantities of cholesterol has been recognized¹ since 1908 and has received wide attention from investigators studying this pathologic thickening of the intima of the aorta. Some workers, especially Anitschkow, have supported the view that atherosclerosis produced by cholesterol in rabbits represents the counterpart of arteriosclerosis in man.¹ Notwithstanding the lack of general acceptance of this idea, interesting chemical and morphologic data have been accumulated from experimental studies of this cholesterol-induced atherosclerosis. Of the results that have been obtained, one of the most interesting is the demonstration that administration of thyroid substances or of iodides prevents the deposition of cholesterol in the arteries, when this sterol is fed to experimental animals.² This observation has been substantiated in several laboratories with both organic and inorganic compounds of iodine. Subsequent investigations have been concerned with attempts to determine the manner in which this element exerts its prophylactic effect. A number of hypotheses have been put forward. Of considerable interest are the recent studies of Turner and Khayat,³ which demonstrate that the ability of iodine to prevent atheromatous changes in rabbits ingesting cholesterol is dependent on the thyroid gland. In the absence of this organ in rabbits, iodine was entirely ineffective in exerting this regulatory role. It appears, therefore, that the action of the iodine is an indirect one working through the thyroid gland. The exact mode of action is not clear, but recent investigations of the chemical alterations of the blood during cholesterol and iodine administration begin to clarify some of the factors involved.

An increase in both the cholesterol and the fatty acids of the blood following the ingestion of cholesterol

dissolved in oil is well established. As Schonheimer⁴ has demonstrated that the lipids which are deposited in the human aorta are of a composition which suggests their infiltration from the blood and deposition without change in composition, the suggestion has been made that only a continued lipemia may cause atherosclerosis. Anitschkow has supported this idea specifically by postulating that the degree of atherosclerosis of the aorta is directly proportional to the level of the blood cholesterol. It therefore seemed logical to believe that the effectiveness of iodides was due to the prevention of lipemia. Recent investigations, however, conducted at the Hospital of the Rockefeller Institute for Medical Research,⁵ have demonstrated that just the contrary occurs with respect to the blood picture. Administration of an organic iodine compound to rabbits receiving cholesterol dissolved in olive oil prevented the appearance of atherosclerosis, which otherwise followed the administration of cholesterol and olive oil. In both groups a persistent lipemia developed, which was, however, more marked in those fed organic iodine in addition to cholesterol. The average content of lipids per hundred cubic centimeters of plasma in the latter group was 2.9 Gm, as contrasted with a value of 2.2 Gm in the animals receiving cholesterol alone. These interesting observations indicate that in iodine-fed rabbits there is no appearance of atherosclerosis despite the existence of a lipemia, which, in the absence of iodine therapy, is associated with the process leading to pathologic alterations of the blood vessels. The authors tentatively assume that the state of metabolism of the tissues, thus influencing the receptivity of these tissues to the deposition of fat, is an important factor in determining whether lipids will be deposited in the arterial walls. This type of variable would offer a partial explanation of the existence of strictly localized atherosclerotic plaques, which has led to the view that atherosclerosis is a focal and not a general morbid change.

Current Comment

NEW OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

Each session of the American Medical Association includes the election by the House of Delegates of those who are to serve the Association in various executive, legislative and judicial capacities for the coming years. In making its choices, the House of Delegates must consider not only the individual capacities of those who are to serve but also the constituencies to be represented, the policies of the organization, and the requirements of the separate situations involved. At the Atlantic City

session the House of Delegates found it necessary to choose two new trustees, since the terms of two men who have given long and capable service to the House terminated on this occasion and since, by the Constitution and By-Laws of the Association, they could not be reelected Dr J H J Upham, who has served with distinction as a member of the Board of Trustees since the year 1923 and recently as its chairman, was retired under this ruling and Dr James R Bloss of Huntington, W Va, was elected to succeed him The term of Dr Joseph A Pettit, who has served on the Board since 1925, terminated, and Dr Ralph A Fenton of Portland, Ore, was the choice of the House for this position The terms of these new trustees will terminate in 1940 At the session of the Board of Trustees immediately following this election, Dr Rock Sleyster of Wauwatosa, Wis, was selected by the Board as its chairman and Dr Austin A Hayden was reelected as secretary The Executive Committee of the Board of Trustees will include Drs Austin A Hayden, Charles B Wright and Arthur W Booth In addition to selecting Dr James Tate Mason of Seattle as President-Elect, the House of Delegates chose Dr Kenneth A Lynch of Charleston, S C, as vice president and reelected Dr Olin West of Chicago as secretary and Dr Herman L Kretschner of Chicago as treasurer Dr Nathan B Van Etten of New York was selected speaker of the House of Delegates to succeed Dr F C Warnshuis, and Dr H H Shoulders of Nashville, Tenn, became vice speaker, succeeding Dr Nathan B Van Etten The President of the Association, Dr James S McLester, announced the appointment of Dr George Edward Follansbee of Cleveland to succeed himself as a member of the Judicial Council, terminating in 1940, Dr Reginald Fitz of Boston to succeed himself on the Council on Medical Education and Hospitals until 1942, and Dr A A Walker of Birmingham, Ala, on the Council on Scientific Assembly for a period of five years By an almost unanimous choice the House of Delegates selected Kansas City as the meeting place for the eighty-seventh annual session of the Association, in 1936 The physicians of Kansas City, who attended the Atlantic City session in great numbers, were unanimous with praise for the new auditorium which will well accommodate

the next session, and promised to do their utmost to surpass the extraordinary meeting that has just been concluded

DR JAMES TATE MASON PRESIDENT-ELECT

The election of Dr James Tate Mason of Seattle to the presidency of the American Medical Association is a recognition of the great achievements of the Northwest, which has on several occasions entertained the American Medical Association at its annual sessions and which has contributed notably to American medical thought Dr Mason was born in Virginia, May 20, 1882 His father was Dr Claiborne Rice Mason of Lahore,

Orange County, Va After receiving his M D degree from the University of Virginia Department of Medicine in 1905, James Tate Mason entered the practice of surgery first at Philadelphia and then at Franklin, Wash He then took up his residence in Seattle, where he has practiced surgery since 1909 From 1916 to 1920 he was surgeon and superintendent of King County Hospital Since 1920 he has been chief surgeon of the Mason Clinic and president of the Virginia Mason Hospital He is consulting surgeon of the United States Marine Hospital at Seattle, the American Mail Line, the Alaskan Steamship Company and the Northern Pacific Railroad Company He is a fellow of the American College of Surgeons and a member of the American Surgical Association, American Association for the Study of Goiter,

JAMES TATE MASON, M D
PRESIDENT ELECT OF THE AMERICAN MEDICAL ASSOCIATION

the Western Surgical Association, the Southern Surgical Association, the Pacific Coast Surgical Association, the Sons of the American Revolution, and other medical societies and organizations In many of these he has occupied positions in an executive capacity In the American Medical Association he was a member of the House of Delegates for six years, between 1928 and 1934, he was secretary of the Section on Surgery, General and Abdominal, from 1923 to 1926, when he was elected chairman, serving in that capacity for one year Dr Mason has contributed notably to the literature of surgery His election is a recognition, incidentally, not only of the great Northwest but also of the state of Virginia, from which have come many notable medical leaders

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE EIGHTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 10 14, 1935

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 10

The House of Delegates convened in the Renaissance Room of the Ambassador Hotel and was called to order at 10 a m by the Vice Speaker, Dr N B Van Etten

Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman Dr J D Brook Michigan who reported that 114 delegates with proper credentials had registered He recommended the seating of the following physicians, who had lost or forgotten their credentials but who had been properly vouched for and whose names appeared on the Secretary's official list Drs T Henshaw Kelly California C G Abell, Vermont John Z Brown Sr, Utah S C Harvey Connecticut, and H H Trout Virginia

On motion of Dr C S Gorsline Michigan, seconded by Dr Burt R Shurly, Section on Laryngology Otology and Rhinology and carried, the report of the Reference Committee on Credentials was adopted

The Vice Speaker declared that the signed attendance slips would constitute the roll of the House for the morning

Adoption of Minutes of Cleveland Session

It was moved by Dr A T McCormack Kentucky seconded by Dr J Newton Hunsberger, Pennsylvania, and carried that the reading of the minutes of the Cleveland session be dispensed with, since they had been published and distributed and that they be adopted with the correction as indicated on page 33

Address of the Speaker, Dr F C Warnshuis

The Vice Speaker, in the absence of Dr F C Warnshuis because of the death of his son read the Speaker's Address which was referred to the Reference Committee on Reports of Officers

Members of the House of Delegates

In greeting you at this opening session of your annual deliberations, I am genuinely grateful for being once more privileged to serve as your presiding officer

The Board of Trustees, councils, bureaus and special committees will present to you their annual reports and recommendations It is the obligation of every delegate to review and study them carefully As delegates, chosen by your fellow members to represent them, you become the spokesmen of the medical profession of this nation In that capacity your actions and decisions create standards and policies for the information and guidance of the Association's officials and the constituent units of our federacy A delegate's responsibility, therefore, is representative and not individualistic In arriving at a final decision, judgment should be based on facts and conditions as they are related to and affect your constituency and not as they concern personal interests or opinions Approaching all of the Association's problems and interests in that spirit will continue the prestige we hold and establish public confidence and endorsement

Your Speaker earnestly recommends that the delegates of every state take the necessary action that will convey to their state organizations a detailed report of all that transpired during this session There is great need for bringing to every member and Fellow clear and intimate knowledge of the policies and activities of the Association as revealed by the endeavors

of officers, trustees, councils and bureaus When our Fellows and members are intelligently informed, misunderstanding will disappear and our efforts will be more achieving It is earnestly requested that you discharge this obligation

REFERENCE COMMITTEES

In appointing Reference Committees, an earnest endeavor is made to make them representative To constitute impartial and open-minded committees is the quest of your Speaker Delegates are urged to attend and participate in the hearings of all Reference Committees Committee chairmen will announce the time and place of their meetings

Your Speaker urges anew that committee chairmen, in making recommendations on resolutions that have been introduced give a brief resume of the representations made before the committee by the proponents and opponents of resolutions Such a resume will be helpful to every delegate

The floor of this House is open to every delegate Before a report or resolution is acted on it will be your Speaker's endeavor to recognize any delegate who desires to address this body Before a vote is taken your Speaker will be painstaking in order that delegates may clearly understand that which they are voting on An impartial and fair attitude will be reflected at all times

CANADIAN MEDICAL ASSOCIATION

The long desired joint session with our Canadian associates in medicine is being realized during this annual session. On behalf of this House of Delegates a very sincere welcome is extended to all the members of the Canadian Medical Association who are in attendance

Scientific medicine knows no national boundaries Medicine is a republic in which its disciples from every country in the world have worked shoulder to shoulder Medicine's combined might has always been directed to obtain the advancement of the science of medicine Medicine is slowly but steadily ascending to the throne of her rightful dominion and, enthroned, will launch her saving edict to the peoples of all nations

Recognizing the universality of medicine, our greeting to our Canadian brothers is warmed in the glow of our cordial fraternal associations We bid them thrice welcome

IN MEMORIAM

Conforming to precedent it now becomes my duty to pay tribute to those of our number who have answered the last call during the past year

A King once said of a prince struck down
Taller he seems in death
And this speech holds truth for now as then
Tis after death we measure men

Our Heroic Dead—James Barrow Hope

Since our last annual session the following Fellows' names are added to the roll of our departed associates (the dates following the names indicate the years of service in the House)

H D Arnold Boston 1908 1913
John Montgomery Baldy, Philadelphia and Devon Pa 1914 (fourth vice president, 1918 1919)
B H Blair Lebanon, Ohio 1910-1911
John A Campbell Williamsport Pa 1924 1927 1929 1931
William F Drewry, Petersburg Va 1907
R U Drinkard Wheeling W Va 1931
Gaston H Edwards Orlando Fla 1925 1931
H L Fancher Chattanooga Tenn 1926
Edward D Fisher New York 1911
Henry N Fitzhugh Westminster, Md 1933 1934
J W Hamilton Mount Vernon Ill 1914 1915
Jabez North Jackson Kansas City Mo 1903 1904 1906 1919 1930
1931 1933 (President Elect 1926-1927 President 1927 1928)
Millard F Jarrett Fort Scott Kan 1915
August F Jonas Omaha 1906 1911 (third vice president 1901 1902)
William Kuykendall Eugene Ore 1926-1931
Ralph W McDowell U S Navy 1934

Gilman Osgood, Rockland Mass 1915 1916 1918 1920
Wendell C Phillips New York 1912 1917 (Trustee 1917 1924 Presi
dent Elect 1925 1926 President 1926 1927)
Clarence Pierson Jackson La 1919 1920
Creswell T Pigot Roundup Mont 1922 1934
Curran Pope Louisville Ky 1912
A. B. Small, Dallas Texas 1915 1916
E. Otis Smith, Cincinnati 1910-1911, 1913 1918 1921
P. W. Tomlinson, Wilmington Del 1907 1908 1919 1926 1931
E. C. Taylor Jackson Mich 1923
Mathew N Voldeng Woodward Iowa 1912 1920 1924
Otho Boyd Will Peoria, Ill, 1902 1906

The world has lost these master workmen For a time we shall grieve that they are dead For a longer time we shall rejoice that they lived

At the request of the Vice Speaker, the members of the House rose and stood for one minute in silent tribute to the memory of departed delegates

Messages of Condolence

Dr A T McCormack, Kentucky, moved that the Vice Speaker and the Secretary send a telegram of condolence in behalf of the House to Dr F C Warnshuis The motion was seconded by Dr J D Brook, Michigan, and carried by a rising vote

Dr Holman Taylor Texas, moved that a telegram of appreciation and sincere good wishes for an early and complete recovery be sent to Dr H M Johnson Minnesota The motion was seconded by Dr J Newton Hunsberger, Pennsylvania, and carried.

Reference Committees

The Vice Speaker presented the following names of members of Reference Committees appointed by the Speaker

SECTIONS AND SECTION WORK

T B Throckmorton Chairman Section on Nervous and Mental Diseases
John W Amessee Colorado
G Henry Mundi Illinois
Isaac A Abt Section on Pediatrics
Holman Taylor Texas

RULES AND ORDER OF BUSINESS

C W Waggoner Chairman Ohio
James R Bloss West Virginia
Buddy Allen Florida
Thomas F Thornton Iowa
Ralph A. Fenton Oregon

MEDICAL EDUCATION

Iryn Abell, Chairman Kentucky
Walter F Donaldson Pennsylvania
George Blumer Connecticut
W H Seemann Louisiana
W D Chapman Illinois

LEGISLATION AND PUBLIC RELATIONS

C E Mongan Chairman Massachusetts
E. M. Pallette California
S P Mengel Pennsylvania
E G Wood Tennessee
John Z Brown Sr Utah

HYGIENE AND PUBLIC HEALTH

J N Baker Chairman Alabama
W F Bowen Kansas
J D Hamer Arizona
V E Simpson Kentucky
O S Wightman New York

AMENDMENTS TO CONSTITUTION AND BY LAWS

J Richard Kevin Chairman New York
A R McComas Missouri
Roy W Fouts Nebraska
McLain Rogers Oklahoma
J Newton Hunsberger Pennsylvania

Address of President Walter L Bierring

The Vice Speaker presented the President, Dr Walter L Bierring, Des Moines, Iowa, who delivered the following address, which was referred to the Reference Committee on Reports of Officers

Mr Speaker and Members of the House of Delegates

It is difficult to find the words adequate to convey to you my appreciation for the honor extended at the Milwaukee session two years ago I can only hope that my efforts in the service of the Association may have merited in some measure this expression of your confidence

It has been a privilege and a rare opportunity, as well as a liberal education, to learn more of the many sided activities of our great association to meet the individual member in his or her home surroundings in some thirty-nine or forty states, and to sense the problems that concern the doctor of today in the various sections of our country

In a trek of some 67,000 miles, many new acquaintances were formed and old friendships renewed, but it was the fine spirit of fellowship and scientific interest manifest everywhere that engendered a feeling of pride and fervent faith that all still goes well in American medicine.

I am not quite clear as to the purpose of this annual address, but I venture to assume that it may be of interest to present some of the impressions gained by these closer contacts, their meaning as I see it, and something of the problems ahead of our association.

Meeting again in this beautiful City by the Sea, I feel inclined to draw a parallel with a former session of this House of Delegates held in Atlantic City thirty-one years ago

On that Monday of June 6, 1904, your predecessors were concerned with questions of great portent to the future practice of medicine which in the sequence of subsequent events has had a definite bearing on the medical, economic and professional problems that concern us in this later day

With the turn of the century a new era began to dawn in American medicine, which was largely the heritage of the remarkable discoveries of Pasteur and the practical methods devised by Koch in bacteriology with the new conception of the causation of infectious diseases, likewise in wound infection with the resulting triumphs of antiseptic and aseptic surgery through the masters Lister and Billroth, as well as those of the brilliant exponents of the art in the New World Furthermore, the introduction of laboratory and clinical instruction, the correlation of physiologic and pathologic changes with study at the bedside, and consequent changes in therapeutic procedure were all dominant influences necessitating a complete transformation of medical education in this country and the character of the educational institutions responsible for such training

For a number of years, various educational forces had given the matter careful study and consideration, but it was the forceful presidential address of Dr Frank Billings at the New Orleans session in 1903 that directed the attention of the Association to the urgent need of improving medical education in America It was particularly emphasized that efforts to elevate the standards of medical training through concert of action among the existing medical schools, state licensing boards and other governmental bodies had not been attainable, and that the only possible way to obtain uniform standards and best influence medical education of the future was through the agency of the organized profession of the entire country The House of Delegates at the session in 1904 here in Atlantic City met the educational challenge of the period by establishing the Council on Medical Education, and the record of its accomplishments in the succeeding years, acting solely as a voluntary agency, is reflected in the comprehensive scheme of uniform medical education operating today in seventy-six approved medical schools, all of which are now established on a university basis

This evolution in medical training has brought in its train many changes affecting the economic and professional status

of the practicing physician, besides distinctly extending the functions and activities of the American Medical Association in many new directions

The impact of the laboratory in diagnostic procedure, the expansion of hospital facilities, the unusual growth of specialism and the development of industrial and preventive medicine have been further factors influencing the changing order of medical practice and the cost of medical care

The delivery of medical service under the new order has gradually engaged an army of nonmedical personnel, such as hospital administrators, laboratory technicians and social service workers, and this, with a constantly increasing nursing profession, has not only added to the burden of illness but, what was possibly more significant, had the tendency to inject influences from without the medical profession affecting the control and character of the medical service to be rendered

It followed as a natural sequence that various philanthropic agencies and foundations assumed the obligation of determining by means of extensive surveys and statistical studies the increasing cost of medical care as compared with that of a generation ago, and likewise venturing a remedy, culminating in the proposals during the past year of the plans for compulsory health and sickness insurance to be established by federal and state legislative action

History has again repeated itself, and the House of Delegates as the governing body of our Association has met the new challenge to the medical practitioner of today, first, by recording itself at the Cleveland session last year in favor of a definite set of principles to guide the medical profession in meeting the problems of the delivery of medical service to all income groups, secondly, by reaffirming these basic principles at the special session of the House of Delegates, February 15 and 16, and registering in strongest terms its firm opposition to all pending and proposed legislation concerned with compulsory health or sickness insurance. Finally it delegated that the service of all administrative and other officers, and particularly the Bureau of Medical Economics, be made fully available for cooperative effort with state and local constituent societies, to unify as far as possible by proper guidance and counsel all local efforts to solve existing problems with all the facilities at the command of the Association. Under direction of this House and through wise provision of the Board of Trustees, the Bureau of Medical Economics has been provided with larger space and clerical assistance to carry on properly the increasing volume of work allotted to the director and his staff

The General Secretary with his alert and comprehensive grasp of changing developments everywhere, and the facile pen and clarion voice of the brilliant editor through the various avenues of publicity in conjunction with inspiring medical leaders throughout the land, have endeavored to sense the thought and existing emergencies in different communities and then to furnish that information and counsel adaptable for the occasion

It has meant a reeducation of our membership as well as of the public regarding the dangers and disappointments attending the operation of systems of compulsory health insurance in the older countries, more accurate information of existing medical economic conditions in the United States, and definite basic principles that must govern the solution of our particular problems

By making this information available as widely as possible, the various ventures proposed by a new school of economic philosophy have been for the time being averted and, perhaps more important, a sounder and more logical thought on the subject has been developed, evidenced particularly by the greater harmony of discussions on medical economic problems at medical society gatherings, as compared with those of but a short time ago

Thoughtful men and women are becoming convinced that private practice will continue to promise the best service for all concerned and insure its high quality. Perhaps the greatest accomplishment of this campaign of education has been the effect on legislation favoring compulsory health insurance and the government control of the practice of medicine

In certain social and economic security measures introduced in Congress, all reference to health or sickness insurance was eliminated, and bills proposing plans for compulsory health insurance presented in one or two state legislatures were

unsuccessful and did not even come up for passage. We must also by no means underestimate the significance of the fact that national legislation favoring compulsory health insurance was not only prevented but even incorporated in any measure presented to Congress

Probably but few outside the states concerned realized the menace of the initiative and referendum measures placed before the people of Oregon, California and Arizona at the elections last fall. A vote of approval would have meant a constitutional amendment becoming a law without executive signature and extending to the various limited practitioners all the rights and privileges of the practice of medicine and surgery and equal rights with physicians in institutions supported by public funds. The defeat of these measures was a distinct accomplishment and was largely due to the valiant efforts of the organized profession in each state to awaken the public conscience to the dangers to public health and the interest of humanity. This was greatly aided by the personal visits and counsel of Dr. Woodward, the director of the Bureau of Legal Medicine and Legislation. Now that certain dangers to the further advancement of scientific medicine are not so much in the foreground as they were a year ago, it is well again to take measure of our opportunities and responsibilities as an organized medical profession to meet the demands of a changing order in modern society

Change has ever been a criterion of progress, and it becomes our obligation to adapt the high purpose of medicine to the needs of the period in which we live.

One of the gratifying impressions gained in contacts with the membership of our association in all parts of the country has been the sustained interest and manifest devotion to scientific medicine

In spite of trying economic conditions, the eagerness, the hunger for new knowledge is indicated by the increasing number of physicians attending medical society meetings, clinical conferences and refresher courses, often requiring considerable sacrifice of time and distance of travel

The American Medical Association exercises one of its particular educational functions by making available for the general practitioner as well as the specialist through its various publications every phase of medical progress, so essential for the continuous development of the experienced physician

The Association recognizes that modern society is showing an increasing interest in matters medical, and through the medium of the efficient Bureau of Health and Public Instruction it maintains an equally important function of educating the public on the importance of well being, the prevention of disease, the principles governing the care of the sick and the achievements of modern scientific medicine. This has tended to fix in the public mind the essential qualifications for the delivery of adequate medical care as well as the ideals and high purposes of the modern physician

The ethical conduct of the physician in all relations to colleague and patient has always been governed by precept and example, and to keep the professional shield untarnished is one of our sacred obligations to our guild and to society. A slip here and there may give cause for criticism from a not too indulgent public and easily reflect on the medical profession as a whole.

Change in methods of medical education has always gone hand in hand with the changing order of the practice of the art. The Association through the work of the Council on Medical Education and Hospitals can point with pride to being the motive force in advancing medical education in this country to its present high plane.

Various studies and surveys within recent years indicate that the needs and demands for medical service are not entirely fulfilled by the prevailing scheme of medical training. The increasing number of medical graduates each year beyond the ability of society to reward adequately is attended by definite social dangers

The House of Delegates at the last annual session authorized a resurvey of existing medical schools under the supervision of the Council on Medical Education and Hospitals, with special reference to faculty personnel and to facilities for clinical teaching with due regard to the number of students admitted in order to determine whether the institution concerned is able to

meet the educational demands of this period and the future practice of medicine. This action is most timely but it is a difficult task and is being most conscientiously carried out though entailing more responsibility even than the inspections and classifications of medical schools made twenty and twenty-five years ago.

This entire movement merits your generous support and encouragement. It was a wise provision to delegate to the Council on Medical Education and Hospitals the supervision of the qualification of the different medical specialties which ensures the highest quality of specialized practice for the future.

The efficiency of organization and close integration of the different services available have made it possible for the Association to maintain a comprehensive grasp of problems and change in medical practice existing in all sections of the country.

It seems particularly fortunate that the Bureau of Medical Economics has been established under such able direction with the ample facilities to meet particularly the emergency demands of the past year. When the report of the director is submitted it will be recognized that no such comprehensive and complete study and analysis of the many existing plans for the delivery of medical service has been attempted by any other organization. The report is further distinctive in that it does not indicate that certain plans must be carried out but rather how they can best be developed for all concerned, which in itself is a real contribution.

It is proper to indicate certain inherent dangers connected with two movements in the interest of the public welfare incident to the present emergency period. The administration of federal emergency medical relief is closely integrated with governmental supervision. The organized medical profession is sympathetic with the humanitarian purpose of this movement but cannot entertain the same feeling toward the extension of the administrative features beyond the present emergency period.

There is probably no wider appreciation of the magnitude and comprehensive nature of the public health program contemplated in the social security act soon to be enacted into law. Fully recognizing the need for the extension and strengthening of public health services in rural and other areas which are without adequate services of this kind one must yet realize that the large sums of money to be allotted to each state annually are far beyond any previous state budgets for public health purposes and that no definite plans have been developed for their proper expenditure.

While the responsibility for carrying out this extensive program is properly placed with the health officer of each state, it becomes the duty of the organized medical profession to assume its share in determining between preventive and curative medicine and to see that the interests of the public health and the medical profession will be equally protected.

If the medical profession is to maintain its nobility of purpose and obligation to society it can only be by the quality of its service and the qualifications of those rendering this service. Therein lies the great opportunity of our association—by unity of effort in conjunction with constituent state and component county medical societies to keep in the pathway of progress and meet the challenge of a changing world.

As a parting word I beg to express my tribute of homage and honor to all of you for your faithful and continuous labors in the House of Delegates for the good of the Association and the glory of American medicine.

Address of President-Elect James S. McLester

The Vice Speaker presented the President-Elect, Dr. James S. McLester, Birmingham, Ala., who presented the following address, which was referred to the Reference Committee on Reports of Officers.

Mr. Speaker and Members of the House of Delegates:

My message today can appropriately be one of congratulation. When you the members of the House of Delegates of the American Medical Association, reaffirmed a few months ago your insistence on the complete professional independence of the American physician you presented in a world of unrest and uncertainty, an inspiring example of clearness of vision and stability of purpose. In opposing all outside control of medical practice, governmental or otherwise you took an important step

toward the maintenance of the present high standards of American medicine. Your action was not only in the interest of the medical profession but also for the good of the American people.

There are additional reasons for congratulation. The efficiency with which this great organization works and its continued progress toward the attainment of its ideals are things which you and I can contemplate with pride. Of great influence in this regard are the officers who labor at its headquarters. I know of no general manager in any corporation who is more responsive to the wishes of his directors than is the Secretary and General Manager in reflecting the views of the House of Delegates. The earnestness and efficiency of his efforts and the wisdom displayed in his management of its affairs contribute enormously to the success of the American Medical Association. I should like to say a word, too, in praise of the high plane on which your brilliant editor conducts the publications entrusted to his care. *THE JOURNAL* beyond comparison is the best periodical of its scope published in any language. Its literary merit is highly pleasing to those who have a conscience for good English while the soundness of its well written editorials and the scientific acumen used in the choice of contributions give it a degree of excellence that is unequalled among medical publications. *Hygieia* likewise fills a genuine need and does this in a most acceptable manner. The House appropriates large sums of money for the activities of the Association. I hope you realize that it is due in large part to the business acumen and untiring efforts of your business manager that you have this money to appropriate. Any organization is fortunate in having such an officer.

You are thoroughly familiar with the scientific activities of the American Medical Association, but I wonder whether even you realize the far-reaching importance of the work done by its several councils and bureaus. I would remind you of the great value at this time of the Bureau of Legal Medicine and Legislation and of the Bureau of Medical Economics and of Health and Public Instruction. In an unobtrusive but highly efficient way the executive officers of these bureaus serve as liaison officers between your headquarters in Chicago and the government in Washington. Few members of the profession realize the intentness with which the American Medical Association watches every movement that would tend to jeopardize medical standards, and the jealousy with which, acting through these bureaus the Association guards the economic welfare and the professional interests of the American physician. The Council on Pharmacy and Chemistry and that on Physical Therapy have given the American physician a saner better balanced view of therapeutics than is possessed by any other physician in the world. These councils have provided him with dependable facts, singularly free of the bias that in other countries usually surrounds the introduction of newer therapeutic measures. Of like influence is the Committee on Foods. The American people is acutely health conscious and will eat anything that it is told is for its good. The astute advertiser knows this and often takes advantage of it, but the Committee on Foods has given to the public in its seal of approval a sign by which foods that are correctly labeled and truthfully advertized can easily be recognized. The influence of this committee is far reaching.

At the risk of being charged with partisanship toward a council on which I have long served I want to say that few forces in the United States are working so consistently and so effectively for the good of the people as is the Council on Medical Education and Hospitals. Thirty-five years ago, just after the Boer War a medical officer of the British army told me this. He said that his government had issued orders to the army in South Africa that graduates of any European medical school be accepted without question for the service, but not the graduates of American schools, these last must be examined. This humiliated me greatly largely because I knew that that order had been issued with good reason. While at that time we had many of the best medical schools in the world we also had the poorest. In fact, it can almost be said that we were distinguished by having all of the poorest. Now, thanks to the Council on Medical Education and Hospitals that is all changed and if I were today to meet that European medical officer I could truthfully say that of the schools that are recognized in this country none can be classed as poor, that our average is

the equal of their best, and that our best is unequalled in the world. But this is only the beginning. Much important work in this field lies ahead and I bespeak for this council your sympathetic help and your continued liberal support.

As the Association continues to grow in strength and usefulness there is the danger that it will take on a separate identity that will lead physicians to look on it as distinct and as far removed from their more intimate state organizations. If such a feeling should develop there would be lost that closeness of contact which is so necessary for the good of our undertakings. The officers and trustees are doing everything possible to forestall such a development, but the greatest responsibility in this regard lies with the members of the House. If you gentlemen will continue to recognize your responsibility, if you will take it on yourselves to keep your constituents advised of the activities of the Association and above all will let them feel that the American Medical Association is quickly responsive to their wishes, that cordiality of feeling between this association and its constituent state associations so necessary for the good of organized medicine will be maintained unimpaired. The several state associations must understand, too, that in the choice of delegates they should continue to select men who have vision and courage, and particularly those who through familiarity with the everyday practice of medicine will be able faithfully to reflect the views of the great body of practitioners for whom it is the privilege of the Association to speak. I think it not inappropriate, too, to remind the fifteen sections that comprise the Scientific Assembly that in the selection of their delegates their choice should rest on men who not only are keenly alert to the needs of that particular division of medicine which they have the honor to represent but also are willing at all times to take a broad interest in all of the deliberations of this House and to make their influence felt.

We have been sailing on rough seas. No doubt there is still some bad weather ahead, but I believe that the worst of the storm has passed and that through the exercise of the same courage, patience, good judgment and steadfastness of purpose which you have exhibited in the past you will be able soon to steer this ship into calmer waters. After that, it will be smooth sailing under bright skies.

REPORTS OF OFFICERS

Report of the Secretary

Dr. Olin West presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary.

Report of the Board of Trustees

Dr. J. H. J. Upham, Chairman, presented the report of the Board of Trustees, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary. He submitted the following supplementary statement: At the last session in Cleveland, the House of Delegates instructed the Board of Trustees to carry on correspondence, or to ask for details in regard to the attempt made by the American College of Surgeons at that time to dominate and control medical practice. Through the Secretary, the Board of Trustees has carried on correspondence, but owing to the recent changes that have occurred the Board of Trustees suggests that this matter be continued for the time being.

Address of Vice President George G. Reinle

The Vice Speaker introduced the Vice President, Dr. George G. Reinle, Oakland, Calif., who addressed the House as follows:

We fully appreciate, Mr. Speaker, and members of the House of Delegates, the honor which you conferred on the California Medical Association and me. I have no address, being conscious of the important business that is to come before the House but I should like to bring this message to you. You realize what we have to contend with in California. You have heard of Upton Sinclair and of many others, but I assure you that, through the efforts of the California Medical Association in guiding legislation, the medical service rendered to the people of California will be in the future, as it has been in the past, not disturbed.

Report of the Judicial Council

Dr. George E. Follansbee, Chairman, presented the following report of the Judicial Council, which was referred to the Reference Committee on Reports of Officers:

To the Members of the House of Delegates of the American Medical Association

Contrary to what might be expected, the amount of work coming before the Judicial Council during the past year has not increased over former years. This might be due to the clarification of the Principles of Medical Ethics accomplished by the House of Delegates at the 1933-1934 sessions, giving a better understanding of the principles and a more active application of them. But one meeting since the last annual session has been necessary to care for the routine activities, which consisted almost entirely of questionable applications for Fellowship and complaints of unethical situations in hospitals.

MEMBERSHIP IN STATE ASSOCIATIONS

It is a practice in a few constituent associations to admit to membership in the state association (1) physicians who are nonresidents of the state and therefore not members in any component society of the state, or (2) physicians resident in the state who for some reason are not members of the county society where they live or practice. Such a procedure is reprehensible in a democratic organization such as the American Medical Association. Membership in the state association and Fellowship in the American Medical Association without membership in a component county medical society extends special privileges not open to other members in the state or the general Fellows in the American Medical Association. The theory on which the American Medical Association is built arises from the broad basis of the county medical society, all of whose members are members of the state association and the national body, and all of whom have definite responsibilities for maintenance of the entire organization. There should be no privileged group to enjoy the advantages presented by the higher bodies without supporting the lower body, which makes the higher bodies possible. The constitution of the Association states that "members in good standing of the constituent association are the members of the American Medical Association, subject, however to the provisions of the by-laws regarding members." Nowhere does the constitution or the by-laws state that membership in a component society is essential to membership in the state society, though the intent is clear in the by-law covering membership and Fellowship in the American Medical Association on transfer of residence from one state jurisdiction to another. Membership in two state associations is as inconsistent as being a voter in two states or two congressional districts. Furthermore, representation in the House of Delegates is based not on the number of members in the county societies of the states but on the number of members in the state association. A state association that carries on its membership roll nonmembers of the component societies may very possibly have an unjustified representation in the House. In the opinion of the Judicial Council, membership in a component society should absolutely be essential to membership in a state association.

IMPROVED METHODS OF ADMINISTERING THE PRINCIPLES OF MEDICAL ETHICS

The Judicial Council in the past has made recommendations to the House of Delegates which, by their recognition and adoption throughout the constituent associations, have resulted in improved conditions under which medical service is made available to the public. Reference especially is made to discussions and pronouncements regarding all forms of contract practice, whether by individual or grouped physicians, hospitals, dispensaries, teaching institutions, or insurance or industrial companies. Much remains to be accomplished, but the course has been clarified and more complete progress awaits only the appropriate action of the chosen representatives of our county, state and national medical organizations.

As the direct result of medical society endeavors to cultivate public understanding of the declared purposes of such societies in relation to sickness prevention and sickness service, public interest in them has been enormously increased in the past five

years. Discussions formerly confined to medical society programs and publications have become public property, and in the public press economic, social and legislative problems having health features, whether such problems are of local or of national interest, are generally acknowledged as the responsibility of the medical profession. With this widening recognition, however, has come a growing convergence of public attention on the motives and the professional activities of the members of our profession, and it is to the disciplinary responsibility of component societies for the ethical conduct of their members that the Judicial Council wishes to call attention at this time.

Public confidence in our avowed declarations for medical control over things medical cannot be successfully cultivated or maintained unless we exclude or remove from the ranks of our organized profession those who ignore our ethical code, especially as it applies to the true professional spirit in our relations with each and every patient. It is apparent that the very democracy of our existing set up may become involved unless our county and state societies rapidly develop to meet adequately local situations arising from the professional activities of a small but thoughtless or indifferent proportion of members. If the societies will not exercise their prerogative or discharge their duties in this connection, will it become advisable to extend the disciplinary functions now resting in the county society to the state association and possibly to the national administration? History, tradition and our constitution stand for local control, but the public policy of our Association has become such that we cannot turn back from it and ethical problems of major importance are pressing for solution.

In general, the Principles of Medical Ethics are accepted as a guide in professional relations and are intelligently and faithfully followed by a large majority of the profession. There are, however, more or less isolated instances in which this is not true. The delinquents comprise individuals, groups and institutions. Solicitation of patients, particularly in industrial practice, unfair competition by clinics and groups and unethical and unlawful practice of medicine by hospitals, dispensaries, insurance companies and universities are examples.

Ordinarily under present by-laws of county, state and national associations procedure to correct an unethical practice must be instituted in the county medical society by the preferring of charges, which in practice is left to some individual who feels aggrieved. Few individuals feel it their personal responsibility to prosecute a breach of ethics that affects them personally but little but which may affect the profession of medicine in a major degree. The institution of charges by an individual in such cases of general concern might very probably in many instances amount to professional suicide, and seldom does any individual desire to place himself on his own initiative in the position of prosecutor for the benefit of the profession as a whole and bring on himself the unfriendliness and antagonism of colleagues often in influential positions. Numerous are the complaints against the situation cited and many are the demands that medical organization correct for its members that which medical organization has pronounced unethical and harmful and which the members cannot correct for themselves. Last year the House of Delegates amended its Principles of Medical Ethics so clearly that there can be no misunderstanding of the conditions mentioned, but the present method of procedure of preferring charges makes the pronouncement ineffective.

The problem is similar to law enforcement in local communities, states and the nation. If in enforcement of the law the institution of proceedings were left to the voluntary action of an individual, personal animus would be the controlling motive and only minor infractions would be handled. Society has found that it needs a system representing society as a whole, of grand jury investigation and indictment, a public prosecutor, and an impartial court with the right of appeal to higher courts. Medicine in this age needs a similar system for enforcement of its ethical and economic principles. Such a system of medical jurisprudence is needed most and would be applicable in the larger county medical societies. The body bringing the indictment and the prosecutor would lose their personal identity in their representation of the medical profession as a whole and no stigma, but rather honor, would attach to them.

It might be advisable to extend the origination of charges in some situations manifestly too great for the county society to handle to the state association and possibly, in rare instances, to the national organization. There rarely would be infractions of such magnitude that the national association and seldom that the state associations should be the originator of any action toward discipline. If and when the House of Delegates sees fit to extend original jurisdiction in matters of discipline to the national organization, the Judicial Council suggests that it should have the duties and powers now conferred on it but it should not at any time be placed in an *ex parte* position. In those instances of abuse of such nature or such magnitude as to warrant national rather than state or county institution of proceedings, there should be some other body, either now in existence or created, to act as grand jury to investigate and, if deemed proper, prepare an indictment against the accused. In case of indictment, the Board of Trustees should assign the prosecution to some one of their choice and the case should be tried before the Judicial Council, which under such procedure would not be under suspicion of prejudice.

The Council wishes to be distinctly understood that it is suggesting no infringement on or release from responsibilities now residing in the component county medical societies. On the contrary, its idea is to assist and complement those societies in performance of the duties now imposed on them and to supplement their activities by methods applicable to conditions and situations too general or too large to be handled within their limited jurisdiction. We commend to the House of Delegates the urgency of prompt and firm action by all component societies in enforcement of the provisions of the Principles of Medical Ethics that will support the growth of public confidence in the sincerity of our avowed ethical principles.

COOPERATION BETWEEN COUNCILS

Some of the common causes of complaints could probably be controlled by a closer coordination between the various councils, particularly the Council on Medical Education and Hospitals and the Judicial Council. The Judicial Council, by the constitution, is the final authority on ethics. Medical ethics follows every member of the American Medical Association, whether in a hospital, a university, a clinic, or not. While the member in such institution is subject to the ethics of the profession, the institution itself as an entity is not, but through the Council on Medical Education and Hospitals sufficient oversight, persuasion and, if needed, pressure can be brought to accomplish what the doctors in such institutions, as individuals, cannot. With such cooperation between the two councils and such enforcing organization as has been suggested, many harmful and obnoxious practices now existing would cease and others not now presenting any large problem would be prevented. The Principles of Medical Ethics, while followed by the large majority of the profession and considered—if considered at all—by many not in the profession as simply a uniform to be worn while “on parade.” When people, laymen as well as members of our profession, realize that the Principles of Medical Ethics are the basic principles of honest, fair dealing and that their observance is necessary to the best interests of the whole people, laymen as well as the members of the profession, medical practice will have taken a long step upward, medicine will have more dignity and authority, and people will be better served.

EMMETT P. NORTH
OLIN WEST, Secretary *ex officio*

Report of the Council on Medical Education and Hospitals

General Merritte W. Ireland, Washington, D. C., presented the report of the Council on Medical Education and Hospitals, which was referred to the Reference Committee on Medical Education.

RESOLUTION ON TRAINING OF INTERNS

General Ireland, in behalf of the Council on Medical Education and Hospitals, then presented the following resolution, which was referred to the Reference Committee on Medical Education

WHEREAS The training of interns is one of the most important phases of medical education for which the responsibility must rest with hospitals rather than with medical schools and

WHEREAS The most advantageous training of interns can be completed only through the intelligent and painstaking efforts of the physicians who compose the staff therefore be it

Resolved That the officers and members of state and county societies be urged to give due consideration to the problems of intern training in the approved hospitals with which they may be connected

Report of the Council on Scientific Assembly

Dr Irvin Abell, Kentucky, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work

NEW BUSINESS

Resolution on Broadcasting Misinformation Pertaining to Medicaments, Foods and Cancer

Dr Holman Taylor Texas, introduced the following resolution, which was referred to the Reference Committee on Hygiene and Public Health

The State Medical Association of Texas, on May 15 1935 unanimously adopted resolutions condemning the broadcasting of misinformation pertaining to medicaments, foods and cosmetics, with particular reference to the curability of cancer As secretary of the State Medical Association of Texas, I was directed to submit this resolution to the House of Delegates of the American Medical Association at its immediately forthcoming annual session in Atlantic City, which, as a delegate to the American Medical Association, I take pleasure in doing The resolution is, for obvious reasons submitted as adopted by the State Medical Association of Texas, as follows

WHEREAS The State Medical Association of Texas and the American Medical Association have repeatedly protested exploitation over the radio of exaggerated claims for medicaments foods and cosmetics without merit and

WHEREAS Attempts have been made in the past and are now being made to evade the restrictions which the United States government has placed on such broadcasting by the establishment of broadcasting stations in Mexico and

WHEREAS There are being broadcast at this time from a station in Mexico false and exaggerated statements concerning the curability of cancer and

WHEREAS Such statements lead not only American citizens but also those of Mexico into the expenditure of money for what is essentially a false and unestablished method of treatment of this disease therefore be it

Resolved That the State Medical Association of Texas present to the Federal Communications Commission of the United States a petition requesting the Federal Communications Commission to inform the government of Mexico concerning the hazards to health concerned in such broadcasting and also that the secretary of the State Medical Association of Texas be authorized to present to the established authorities of Mexico concerned with the control of broadcasting from that nation the facts in relationship to this fraudulent broadcasting of a cure for cancer and request such authorities to exercise their power in discontinuing this menace to the citizens of both republics

Resolution on Appointment of Committee to Investigate and Formulate Standards Governing the Manufacture of Catgut for Surgical Use

Dr Grant C Madill New York, presented the following resolution, adopted by the house of delegates of the Medical Society of the State of New York, which was referred to the Reference Committee on Miscellaneous Business

WHEREAS The qualities desired in catgut for human use are absolute sterility and absorbability and

WHEREAS Most catgut supplied for service on human bodies is manufactured for profit and

WHEREAS Recent reports indicate that infected catgut or incompletely sterilized catgut is being sold and

WHEREAS This constitutes a menace to the public be it

Resolved That the house of delegates of the Medical Society of the State of New York, through its delegates to the American Medical Association memorialize the House of Delegates of the American Medical

Association to set up a committee or such agencies as will investigate and elaborate standards and in general formulate a policy in regard to catgut as will safeguard the community

Resolution Seeking the Enactment of National Legislation to Obviate the Evil of Radio Broadcasting of Medical Misinformation

Dr James F Rooney, New York, presented the following resolution, adopted by the house of delegates of the Medical Society of the State of New York which was referred to the Reference Committee on Legislation and Public Relations

WHEREAS The public health is undermined by radio broadcasts purporting to impart medical information to the public either as sustaining programs or as part of advertising campaigns and

WHEREAS This information is usually broadcast by nonmedical persons who can hardly realize the fallacies of the things they broadcast and

WHEREAS This leads to misinformation which conceivably also might cause health damage to those of the listening audience who followed it therefore be it

Resolved That the house of delegates of the Medical Society of the State of New York instruct their delegates to the American Medical Association to bring this to the attention of the House of Delegates of the American Medical Association to the end that suitable national legislation be enacted to obviate this evil and threat to the public health

Resolutions on Contraception

Dr George W Kosmak New York presented the following resolution adopted by the house of delegates of the Medical Society of the State of New York

WHEREAS State and federal legislation governing control of reproduction is conflicting and renders certain phases of medical practice illegal it is important that the medical profession as a whole should undertake to clarify and lead in the solution of these questions which involve medical practice and procedures The importance of such control in medical practice where such control constitutes a therapeutic measure is obvious to all medical men

Resolved That the house of delegates of the Medical Society of the State of New York recommends to the House of Delegates of the American Medical Association that it officially sanction the appointment by the Board of Trustees of a committee to study carefully all these related problems and formulate at least a preliminary report to be presented to the 1936 session of the House of Delegates of the American Medical Association

It was moved by Dr William H Mayer, Pennsylvania seconded by Dr E G Wood Tennessee, and carried, that a Special Reference Committee be appointed to consider this subject and the Vice Speaker announced that such committee would be appointed and the matter brought before the House in Executive Session

The Vice Speaker also referred to the Special Reference Committee, without reading, similar resolutions received from the following societies Arkansas Medical Society, Berks County (Pa.) Medical Society, Chicago Orthopedic Society, Clinico-Pathological Society of Washington, D C Medical Society of the District of Columbia, Gage County (Neb.) Medical Society, Maine Medical Association, New Mexico Medical Society, and Portage County (Ohio) Medical Society

Resolution on Solicitation of Votes

Dr Isaac A Abt, Section on Pediatrics presented the following resolution, which was referred to the Judicial Council

Under the Standing Rules of the House of Delegates page 53 of the Constitution and By Laws a section entitled Solicitation of Votes, adopted by the House of Delegates at Saratoga Springs N Y June 13 1902 reads as follows Resolved That it is the sense of the House of Delegates of the American Medical Association that the solicitation of votes for office is not in keeping with the dignity of the medical profession nor in harmony with the spirit of this Association and that such solicitation shall be considered a disqualification for election to any office in the gift of the Association.

Resolved That the Judicial Council be requested to inform this House of Delegates whether said section of the Standing Rules is still in force and whether any person who is elected or nominated in violation of said rule is legally eligible for nomination or election to an office in the American Medical Association

Resolutions on Contraception

Dr Leonce J Kosminsky, Arkansas, presented the following resolutions adopted by the Arkansas Medical Society, which were referred to the Special Reference Committee

WHEREAS The provisions of section 211 245 311 and 312 of the United States Penal Code dealing with contraception

(1) Seriously reflect on the integrity and propriety of the medical profession

(2) By hampering physicians in private and clinical practice in obtaining supplies tend to prevent them from giving adequate contraceptive advice even in cases where it is necessary to conserve health or life itself

(3) Prevent the publication of all contraceptive information in medical textbooks and medical journals resulting in widespread ignorance on the part of the medical profession on this important subject and interfering with the instruction of medical students and practitioners concerning it and

(4) Constitute an unwarranted interference of the United States with the right of each state to control the practice of medicine within its jurisdiction as it may see fit and

WHEREAS Legislation is now pending in the Congress that if enacted into law would make the provisions of the federal penal statutes concerning contraception even more rigorous and

WHEREAS, The whole subject is seriously in need of scientific study and investigation in order that standards of effectiveness and safety may be set up and

WHEREAS The medical profession and the public have the right to look to the American Medical Association to assume the role of leadership in both the scientific and the legal phases of contraception therefore be it

Resolved That the house of delegates of the Arkansas Medical Society requests the House of Delegates of the American Medical Association to initiate a comprehensive program with respect to contraception instructing its appropriate agencies to undertake the necessary scientific study and to make every legitimate effort to have federal and state laws so amended as to remove restrictions now affecting physicians and that the secretary be instructed to forward a copy of this resolution to the Secretary of the American Medical Association and he it further

Resolved That the delegates of the Arkansas Medical Society to the American Medical Association be instructed to urge and vote for such a program

Dr Henry C Macatee, District of Columbia, introduced the following resolutions, adopted by the Medical Society of the District of Columbia, which were referred to the Special Reference Committee

WHEREAS The medical profession and the public have the right to look to the American Medical Association to assume a role of leadership in both the scientific and the legal phases of all branches of medical practice, and

WHEREAS The whole subject of birth control is seriously in need of scientific study and investigation be it

Resolved That the Medical Society of the District of Columbia request the House of Delegates of the American Medical Association to initiate a comprehensive program with respect to the study of birth control instructing its appropriate agencies to undertake the necessary scientific study and he it further

Resolved That our delegate to the House of Delegates be instructed to urge and vote for the adoption of such a program of investigation and that the secretary be hereby instructed to forward a copy of these resolutions to the Secretary of the American Medical Association

Resolution on Care of the Indigent

Dr Henry C Macatee, District of Columbia, presented the following resolution adopted by the Medical Society of the District of Columbia which was referred to the Reference Committee on Medical Economics

WHEREAS The American Medical Association at its session in Milwaukee in 1933 endorsed the Minority Report of the Committee on the Costs of Medical Care which recommends that Government care of the indigent be expanded with the ultimate object of relieving the medical profession of this burden, and

WHEREAS Physicians bear and under any conditions will continue to bear an enormous part of this burden as their private philanthropy growing out of their habitual acceptance of personal and individual obligations to the poor and since therefore the recommendation quoted refers to the burden of medical care for that large class of indigent which is a direct charge on society as a whole and

WHEREAS, Since this particular burden is preponderantly undertaken by the medical profession because of the very real but intangible advantages of increased experience skill and prestige that are to be derived from appointments to hospital and dispensary staffs a situation is created that results in (1) a tendency to promote and facilitate the practice of medicine by hospitals (2) a demonstrable failure to provide adequate care for other than the more serious medical hazards of the indigent group and (3) lack of protection to society as a whole against the spread of infectious diseases of all types from the foci thus maintained and

WHEREAS The desire to provide adequate medical care for this group should not be based on a lofty altruism alone but equally as has been indicated on sound considerations affecting the public health and on the very necessary realization on the part of the medical profession that it cannot expect and should not attempt to attain economic security for itself except as a by-product of a social readjustment that assures the availability of the curative preventive and rehabilitating facilities of modern medicine to all classes of the people including the entirely indigent and

WHEREAS All current plans whether sponsored by medical or socio-economic groups, for effecting a wider and more uniform availability of medical facilities for all fail adequately to provide curative, to say nothing of preventive medical care for the indigent and

WHEREAS Any plan keeping within the confines of a capitalistic rather than a socialist concept of society must, from the point of view of equity as well as from that of practical accomplishment recognize the profit motive (using this term in its strict economic sense) on the part of physicians if their services are to be secured for this group therefore be it

Resolved That the Medical Society of the District of Columbia urge the House of Delegates of the American Medical Association to request the Board of Trustees to instruct the Bureau of Medical Economics in evaluating any plans for securing medical economic security to give due weight to the facts set forth in this preamble and to study, investigate, and at the next session report as to the advisability of securing adequate funds to be derived from public taxation to remunerate physicians for services that while rendered to the indigent are in the interest of and hence properly chargeable to society as a whole and as to methods for assuring that such funds shall be so administered and disbursed as to avoid a bureaucratic control subject to political exploitation

Resolution on Medical Service Organizations

Dr Henry C Macatee District of Columbia, introduced the following resolution adopted by the Medical Society of the District of Columbia, which was referred to the Reference Committee on Medical Economics

WHEREAS At the meeting of the American Medical Association at Milwaukee in 1933 the House of Delegates endorsed "the Minority Report of the Committee on Costs of Medical Care as expressive in principle of the collective opinion of the medical profession" commended the plan of the Medical Society of the District of Columbia to educate and inform its constituency regarding the socio-economic aspects of medical practice, and recommended similar activities to the favorable consideration of other constituent associations and

WHEREAS Among the recommendations of the said Minority Report the following may be found That steps be taken to bring about better coordination of the medical resources of the communities of the Nation, and that careful trial be given to methods which can rightly be fitted into our present institutions and agencies without interfering with the fundamentals of medical practice, and

WHEREAS Under the impetus of the said report bearing the endorsement of the American Medical Association many constituent county and state societies have set up experimental medical service organizations for the accomplishment of the two recommendations quoted with the result of creating widespread interest in the movement and a desire on the part of other communities to profit by the experience of existing projects before setting up similar experiments of their own and

WHEREAS It has been the experience of those conducting the management of such medical service bureaus that the details of organization and administration cannot successfully be conveyed by written description and

WHEREAS It has been the experience of the Medical Economic Security Administration for the District of Columbia probably duplicated by the experience of similar projects elsewhere that the demand for information and assistance cannot be met by local resources of time and money and personnel therefore be it

Resolved That the House of Delegates recommend to the Board of Trustees that the more promising of the medical service organizations operating under the auspices of constituent societies of the American Medical Association be, by invitation taken under the sponsorship of the American Medical Association as its collective experimental endeavor to bring about an acceptable adjustment of medical resources to popular needs and that funds be appropriated to be expended through the Bureau of Medical Economics (a) in the form of grants to meritorious projects when necessary or advisable to carry them from their inception until self supporting or for undertaking necessary or desirable additions to the base experiment for statistical or other purposes and (b) to provide for the free exchange of methods of organization and operation and experience in administration by defraying the necessary travel and other expenses of executive personnel of such projects in operation or in process of formation or in such other ways as may be found necessary or desirable

Resolution on Preparation of a Statement Regarding Medical Service Experiments

Dr Henry C Macatee, District of Columbia, presented the following resolution, adopted by the Medical Society of the District of Columbia, which was referred to the Reference Committee on Medical Economics

WHEREAS The American Medical Association has repeatedly expressed its opposition to any form of state administered health insurance and has presented cogent reasons for its opposition and

WHEREAS, One of the controlling reasons for opposition is that no experimental approach to the application of the principle of state health insurance in America has been proposed and no such experimental

approach can be made without setting up politically controlled machinery expensive to maintain and difficult to destroy and

WHEREAS In view of the universally recognized need of better adjustment of medical resources to the requirements of the people in the low income class the medical profession has undertaken in many parts of the country to effect the needed readjustment by the use of social devices suited to the problems and facilities of the respective localities and

WHEREAS The American Medical Association has undertaken the sponsorship of these projects for the purposes of study coordination and extension therefore he it

Resolved That the Board of Trustees cause to be prepared a statement setting forth the number and location of the medical service experiments under the supervision and sponsorship of the American Medical Association their purposes and accomplishments and transmit the same to the President of the United States as an evidence that the medical profession itself is endeavoring in a truly scientific experimental way to solve the problems of medicosocial maladjustment by utilizing methods and agencies familiar to the American people and integral with American life

Resolution on Establishment of Courses in Medical Economics in All Medical Colleges in This Country

Dr Walter F Donaldson, Pennsylvania, introduced the following resolution, sponsored by the board of trustees of the Medical Society of the State of Pennsylvania which was referred to the Reference Committee on Medical Education

WHEREAS The Committee on Medical School Curricula of the Commission on Medical Economics of the Philadelphia County Medical Society has collected data as indicated by the accompanying table indicating a receptive attitude on the part of the faculties of the medical colleges of the United States toward the establishment of courses in medical economics in these schools in that sixty of the seventy-one class A medical schools of the country have established or are willing to establish such courses

Therefore the Board of Trustees of the Medical Society of the State of Pennsylvania has instructed its delegates to the House of Delegates of the American Medical Association to introduce this resolution at the Atlantic City session urging the Council on Medical Education and Hospitals and the Bureau of Medical Economics of the Association to continue their endeavors until courses in medical economics have been established in all the medical colleges in this country

THE PHILADELPHIA COUNTY MEDICAL SOCIETY COMMISSION ON MEDICAL ECONOMICS

Section for Investigation of Certain Phases of Teaching in Medical Schools Joseph W Post MD Chairman

ANNUAL REPORT

The Section for Investigation of Certain Phases of Teaching in Medical Schools has conducted a survey covering seventy-one recognized medical colleges throughout the United States to ascertain those colleges which are at present teaching medical economics as well as the attitude of the deans as to the value of such teaching

With this end in view the following questionnaire was prepared and mailed to the dean of each of the seventy-one institutions

- 1 University of Oklahoma School of Medicine Oklahoma City
- 2 State University of Iowa College of Medicine Iowa City
- 3 University of Colorado School of Medicine Denver
- 4 Yale University School of Medicine New Haven Conn
- 5 University of Pennsylvania School of Medicine Philadelphia
- 6 Hahnemann Medical College Philadelphia
- 7 New York Homeopathic Medical College and Flower Hospital, New York
- 8 University of North Dakota School of Medicine Grand Forks N D
- 9 University of Minnesota Medical School Minneapolis
- 10 Tulane University of Louisiana School of Medicine New Orleans
- 11 Albany Medical College Albany N Y
- 12 University of Michigan School of Medicine Ann Arbor
- 13 University of Louisville School of Medicine Louisville, Ky
- 14 University of Cincinnati College of Medicine Cincinnati
- 15 Temple University School of Medicine Philadelphia
- 16 Georgetown University School of Medicine Washington D C
- 17 University of Vermont College of Medicine Burlington Vt.
- 18 University of Missouri School of Medicine Columbia Mo
- 19 University of Alabama School of Medicine Mobile
- 20 Loyola University School of Medicine Chicago
- 21 Baylor University College of Medicine Dallas Texas
- 22 Boston University School of Medicine Boston
- 23 University of Oregon Medical School Portland
- 24 Columbia University College of Physicians and Surgeons New York
- 25 University of Pittsburgh Pittsburgh
- 26 Creighton University School of Medicine Omaha
- 27 College of Medical Evangelists Loma Linda Los Angeles
- 28 Women's Medical College of Pennsylvania Philadelphia
- 29 University of Kansas School of Medicine Lawrence and Kansas City Kan
- 30 Emory University School of Medicine Atlanta Ga
- 31 Rush Medical College University of Chicago
- 32 University of Illinois College of Medicine Chicago
- 33 Washington University School of Medicine St Louis
- 34 Indiana University School of Medicine Bloomington and Indianapolis
- 35 Medical College of the State of South Carolina Charleston
- 36 University of Georgia School of Medicine Augusta
- 37 University of Texas School of Medicine Galveston

- 38 Harvard University Medical School Boston
- 39 Western Reserve University School of Medicine Cleveland
- 40 University of Nebraska College of Medicine Omaha
- 41 University of Arkansas School of Medicine, Little Rock
- 42 Tufts College Medical School Boston
- 43 Stanford University School of Medicine San Francisco
- 44 University of California Medical School, Berkeley and San Francisco
- 45 Duke University School of Medicine Durham N C
- 46 Cornell University Medical College Ithaca N Y
- 47 Johns Hopkins University School of Medicine Baltimore
- 48 School of Medicine of Division of Biological Sciences University of Chicago
- 49 Dartmouth Medical School Hanover N H
- 50 Ohio State University College of Medicine Columbus
- 51 St Louis University School of Medicine St. Louis
- 52 Louisiana State University Medical Center New Orleans
- 53 University of Rochester School of Medicine, Rochester N Y
- 54 University of Maryland School of Medicine and College of Physicians and Surgeons Baltimore
- 55 University of North Carolina School of Medicine Chapel Hill
- 56 University of Mississippi School of Medicine University
- 57 Wayne University School of Medicine Detroit
- 58 New York University University and Bellevue Hospital Medical College New York
- 59 Long Island College of Medicine Brooklyn
- 60 University of Southern California School of Medicine Los Angeles

The colleges which did not respond to the questionnaire were

- 1 Jefferson Medical College Philadelphia
- 2 George Washington University School of Medicine Washington D C
- 3 Howard University College of Medicine, Washington D C
- 4 Northwestern University Medical School, Chicago
- 5 Syracuse University College of Medicine, Syracuse N Y
- 6 University of Buffalo School of Medicine Buffalo
- 7 University of South Dakota School of Medicine Vermillion
- 8 University of Tennessee College of Medicine, Memphis
- 9 Vanderbilt University School of Medicine Nashville Tenn
- 10 University of Virginia Department of Medicine Charlottesville Va
- 11 University of Wisconsin Medical School Madison

Following is a copy of the questionnaire sent to all the medical schools above referred to

Feb 21, 1935

Dear Sir —

As chairman of the Section for Investigation of Certain Phases of Teaching in Medical Schools of the Philadelphia County Medical Society I am endeavoring to get a general survey of the same and am requesting your hearty cooperation

With this end in view would you kindly answer the following questions and make any additional comments which you might deem helpful to this study

- 1 (a) Is the subject of medical economics given any consideration in your college curriculum? (b) If so will you forward outline and particulars of same?
- 2 What is your attitude toward the teaching of medical economics to the undergraduate medical student?
- 3 Do you believe that a comprehensive survey of the subject as well as training in actual business methods in practice would make the graduate a more valuable asset to his profession and community?
- 4 When do you consider the most propitious time for teaching this subject and how could it best be accomplished?
- 5 Would you be willing to cooperate with your local county medical societies in an effort to instruct students along these lines?
- 6 Is any stress laid on the teaching of periodic health examinations other than the regular routine subject of physical diagnosis?

Our Commission on Medical Economics of the Philadelphia County Medical Society feels that a great benefit can be derived from a careful consideration of the foregoing and therefore trust that you will add your valuable counsel

Respectfully yours

JOSEPH W Post MD Chairman
1930 Chestnut St Philadelphia

To date we have received replies from sixty (83 per cent) of those to whom questionnaires were sent and our analysis of each of the five questions is as follows

QUESTION 1—(a) Is the subject of medical economics given any consideration in your curriculum? (b) If so will you forward outline of same?

Thirty-three or 55 per cent are teaching this subject either by a set course or by lectures in some form

Twenty-seven or 45 per cent give the subject no consideration

The thirty-three colleges registering in the affirmative are as follows
Nos 1 3 4 9 10 11 14 15 18 24 26 27 28 29 30 31 32 33
34 35 40, 44 45 46 47 48 50 51, 52 57 58 59 60

Those colleges giving no consideration to the subject are Nos 2, 5
6, 7 8 12 13 16 17 19 20 21 22 23 25, 36, 37 38 39 41
42 43 53, 54 55 56 49

QUESTION 2—What is your attitude toward the teaching of medical economics to the undergraduate medical student?

This question was answered favorably by forty-eight (80 per cent) of the colleges as follows Nos 1 2 3 8 9 10 11 12 13 14 15 16
18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35
36 37 43 45 46 47 48 50 52 53 54 55 56 57 58 59 60

Unfavorable replies were registered from ten (17 per cent) of the colleges as follows Nos 4 5 6 7 38 39 40 42 44 51

Institutions 41 and 49 did not answer this question

QUESTION 3—Do you believe a comprehensive survey of the subject as well as training in actual business methods in practice would make the graduate a more valuable asset to his profession and community?

Forty-one, or 69 per cent of those replying answered in the affirmative and comprised the following Nos 1 2 3 5 9 10 11 12 13 14 15 16 17, 18 19, 21 22 23, 24 25, 26 27 28 30 31 32 33 34 35 36 40, 45 46 50 52 53 54, 55 57 59, 60

The unfavorable replies were from Nos 4 6 7 8 29 17 38 39 42, 43 44 47, 48 51, 56 58 a total of sixteen or 26 per cent

Nos 20 41 49 did not answer the question This represents 5 per cent.

QUESTION 4—When do you consider the most propitious time for teaching this subject and how could it best be accomplished?

1st year	1
2d year	1
3d year	2
3d and 4th years	6
4th year	43
Intern's year	3
Intern's year	1
Societies	1

One college felt that it should be incidental as the occasion arose
Ten colleges did not answer the question

QUESTION 5—Would you be willing to cooperate with your local society in an effort to instruct students along this line?

Forty-one (68 per cent) answered affirmatively

Eight (13 per cent) answered negatively

Eleven (18 per cent) gave no answer

Supplementing the replies to the questionnaire we have obtained some valuable data from those institutions which are already teaching medical economics

The individual comments from the authors of these replies constitute we feel, a favorable attitude toward the necessity for enlarging on the teaching of this important subject

Our committee therefore recommends that the résumé of this survey be referred through proper channels to the Bureau of Medical Economics of the American Medical Association with resolutions that a course in medical economics be added to medical college curricula

The committee would also suggest that the data of those courses and lectures obtained from this survey be used as a basis for such a training

We would furthermore recommend that a copy of this report be mailed to each of the deans of the colleges contacted along with a letter of thanks to those responding for their whole hearted cooperation

The committee desire to acknowledge their sincere appreciation to Mr Franklin M Crispin and the Secretarial staff of the Philadelphia County Medical Society for their valuable assistance in making this survey

Respectfully submitted

JOSEPH W POSE, M.D. Chairman

Resolution Making Membership a Prerequisite for Qualification as Specialist on List of Council on Medical Education and Hospitals

Dr William R Brooksher, Arkansas, presented the following resolution, adopted by the Arkansas Medical Society, which was referred to the Reference Committee on Medical Education

WHEREAS The Council on Medical Education and Hospitals of the American Medical Association has published a list of qualified specialists in pathology and radiology these physicians having been found to qualify according to essentials proposed by the Council on Medical Education and Hospitals and approved by the House of Delegates of the American Medical Association and

WHEREAS Such a listing is felt to be a definite contribution toward the elevation of the standards of these specialties and

WHEREAS These essential qualifications do not include the requirement that a physician so designated shall be a member of his county and state medical society therefore be it

Resolved That the House of Delegates of the American Medical Association request the Council on Medical Education and Hospitals of the American Medical Association to make membership in respective county and state medical societies a prerequisite for qualification as a specialist on the Council's list.

Special Reference Committee

The Vice Speaker appointed the following as members of the Special Reference Committee

E R Cuniff, Chairman	New York
A A Walker	Alabama
J Allen Jackson	Pennsylvania
E H Cary	Texas
T Henshaw Kelly	California

The meeting recessed at 12 25 p m to reconvene on Tuesday morning, June 11, at 9 30

(To be continued)

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45 Chicago daylight saving time (3 30 central standard time) The next broadcast will be as follows

June 27 Blood and Fire, W W Bower M D

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION, PUBLIC HEALTH ETC)

ARIZONA

State Medical Election.—Dr Jesse D Hamer, Phoenix, was chosen president-elect of the Arizona State Medical Association at its annual meeting in Phoenix, April 24-27, and Dr Charles R. K. Swetnam, Prescott, was inducted into the presidency The next annual session of the society will be held at Nogales in May 1936 Guest speakers included Drs Frederick C Warnshuis, San Francisco, secretary, California Medical Association, Rexwald Brown, Santa Barbara, Calif., Frank S Dolley, Los Angeles, "Present Status of Pulmonary Lobectomy for Bronchiectasis and Carcinoma", Frederick A. Willius, Rochester, Minn., "The Physiologic Approach to the Treatment of Heart Failure", Erwin W Johns, Albuquerque, N M, "Juvenile Osteochondrodystrophies," and Howard Fleming, San Francisco, "Diagnosis and Treatment of Head Injuries"

CALIFORNIA

Personal.—Dr Mary Bennett Ritter, Berkeley, was awarded the honorary degree of doctor of laws at the commencement of the University of California, May 18 —Dr Walter E Coppedge, Alturas has been appointed health officer of Modoc County to succeed Dr John Stile.—Dr and Mrs Frank J Gobar Fullerton, celebrated their golden wedding anniversary, June 10

Outbreak of Infantile Paralysis.—An outbreak of infantile paralysis has occurred among the attendants at the Los Angeles County General Hospital, Los Angeles, according to the Chicago Tribune June 17 Thirty-eight positive cases were reported, June 16, among nurses and patients, and sixty-seven cases were under observation. In the week previous to this report, twenty-four cases of the disease were detected at the hospital, four were patients and twenty student nurses

Bills Passed.—The following bills have passed the senate and the assembly S 155, proposing to amend the medical practice act so as to authorize the board of medical examiners to issue a physician's and surgeon's certificate to an applicant who, although failing to furnish documentary evidence satisfactory to the board that he has completed a resident course of instruction fulfilling the requirements of the act, presents a diploma issued to him by a medical school approved by the board and in addition files satisfactory documentary evidence of having either completed the fourth year in an approved medical school in the United States or served at least one year's residence in a hospital in the United States approved by the board for internship, S 468 proposing to amend the medical practice act so as to authorize courts on the application of the state board of medical examiners to enjoin the unlicensed practice of medicine, and S 534, proposing to prohibit the admittance of any person to a private psychopathic institution, or any institution for the care

and treatment of persons mentally ill or deranged, without a written statement from at least two licensed physicians that they have examined the patient and that he should be admitted for care and treatment and proposing further that any person in an institution for the care and treatment of the mentally ill must be permitted to communicate at any time with whomsoever he desires. A 1037 has passed the assembly, proposing to make it unlawful for any person to own, possess, or operate any x-ray device or x-ray laboratory unless such device or such laboratory is operated under the direct supervision of a person licensed by the state board of health. S 392 has passed the senate, proposing to make it unlawful to conduct a clinical laboratory unless it is under the immediate direction of a licensed clinical laboratory technologist licensed by the state board of health. The provisions of the bill however, are not to apply to any licensed physician maintaining a laboratory in his own office for use in his own practice.

COLORADO

Society News—At a joint meeting of the Delta, Montrose and Mesa county medical societies in Delta, May 24, a symposium on cancer of the digestive tract was presented by Drs. John B. Crouch, John B. Hartwell and William F. Drea, Colorado Springs—Dr. Roy P. Forbes, Denver, addressed the Fremont County Medical Society, April 23, in Canon City, on "Commonly Missed Diagnoses in Pediatrics"—The Northeast Colorado Medical Society was addressed in Sterling, May 9, by Dr. Casper F. Hegner, Denver, on pulmonary surgery.

Dr. Freeman Honored—The completion of fifty years in the practice of medicine by Dr. Leonard Freeman, professor of surgery, University of Colorado School of Medicine, was observed at a dinner in his honor, June 3, given by the Medical Society of the City and County of Denver. Dr. Casper F. Hegner was toastmaster and Dr. Edward F. Dean, president of the society, presided. Speakers included Drs. George P. Johnston, Cheyenne, Wyo., on "Dr. Freeman, the Teacher," Thomas A. Stoddard, Pueblo, "Freeman, the Man," and George H. Curfman, Salida, "Dr. Freeman's Influence on Surgery in the West." Dr. Emmet Rutherford, professor of surgery emeritus, Stanford University School of Medicine, San Francisco, spoke on "Fifty Years a Surgeon." The presentation of a portrait was made by Dr. Glen E. Cheley and Dr. Frank W. Kenney gave the speech of acceptance. Dr. Freeman was president of the Colorado State Medical Society from 1909 to 1910.

CONNECTICUT

Society News—Dr. Charles J. Bartlett, New Haven, was chosen president of the Connecticut Association of Public Health and Clinical Laboratories at its meeting in Torrington, May 17, and Dr. Louis P. Hastings, Hartford, vice president—Dr. George T. Pack, New York, addressed the New Haven Medical Association, May 15, on "Indications for Radium and X-Ray Therapy of Cancer."

Mental Hygiene Meeting—Charles-Edward A. Winslow, Dr. P. H., New Haven, was reelected president of the Connecticut Society for Mental Hygiene at its twenty-seventh annual meeting in Bridgeport, May 20. Dr. C. Charles Burlingame, Hartford, was made vice president. This was a joint session with the Bridgeport Society of Mental Hygiene which was holding its eleventh annual meeting.

Bills Enacted—The following bills have become laws: H 852, repealing the laws regulating the possession, sale or distribution of narcotic drugs and enacting what apparently is the uniform narcotic drug act, S 101, authorizing the state department of health to investigate the cause and the prevention and treatment of cancer and to take such steps as may be necessary to reduce the mortality due to cancer, and S 222, amending the law requiring the licensing of institutions for the treatment and care of insane persons or persons suffering from other abnormal mental or nervous conditions, by authorizing the state department of health rather than the governor, to license such institutions annually, to prescribe a sanitary code for the government of such institutions and to revoke licenses for stated causes.

ILLINOIS

Stream Pollution—A study of the Fox River from Aurora to its mouth at Ottawa has been begun as a part of the state campaign against stream pollution now under way by the Illinois Department of Health. According to plans the improved sanitation of the Fox River will be completed within the next two years.

Tuberculosis Declines in Young Persons—Evidence that death from tuberculosis is decreasing in persons under 20 years of age is revealed in a survey recently completed by the state department of health. For this age group only fifteen deaths per hundred thousand population were charged against tuberculosis in 1934 as compared with a rate of 50 in 1920. The rate was 71 in 1934 for persons over 20 years of age. The recent study shows a marked reduction in mortality from tuberculosis among persons under 20 since 1920.

Commission for Crippled Children—The Illinois Commission for Physically Handicapped Children was recently created under a legislative act to obtain and keep a register of physically handicapped children, coordinate all state activities that aim to benefit such children and promote voluntary work in this field. All persons under 21 years of age are regarded as children in the law that created the commission. Mr. Bruce Campbell, East St. Louis, is chairman of the commission, and other members, appointed by the governor include Dr. Edward L. Compere, Dr. Henry Bascom Thomas, Miss Edna Foley and Mr. Jacob Kepects, Chicago, and Mr. Harry Warner, Dixon. Mr. A. L. Bowen, state director of public welfare, Mr. John A. Wieland, state superintendent of public instruction, and Dr. Frank J. Jirka, state health director, are ex officio members of the commission.

CHICAGO

Death of Boy from Rabies—The death from rabies of a boy, 17 years of age, occurred June 15. According to the *Chicago Tribune*, the boy had been bitten by the family dog, May 18.

Personal—Surg. Gen. Robert U. Patterson, U. S. Army, Washington, D. C., was the guest of honor and principal speaker at the annual dinner of the Medical Chapter of Cook County, Reserve Officers Association, May 24.

Maximum Penalty Imposed on Quack—Municipal Judge Erwin J. Hasten imposed, May 16, the maximum penalty of one year in the county jail and a \$500 fine on Raphael Lee, who had been charged with practicing medicine without a license. Witnesses stated that he sold pills which he declared would cure all illnesses, the *Chicago Tribune* reported. This action is part of a campaign against quacks and fake healers now being conducted by the Illinois State Department of Registration.

Foundation Renews Grant for Biologic Research—The Rockefeller Foundation will continue for three more years its grant of \$50,000 to the Division of Biological Sciences, University of Chicago, for research in biology. The foundation has been aiding this project since 1929 with annual grants of \$30,000. Last year, however, the fund was increased to \$50,000, the additional money to be used to cover the expenses of the sex research program which had been financed by the committee on research in problems of sex of the National Research Council (*THE JOURNAL*, Nov. 10, 1934, p. 1458).

IOWA

Tuberculosis Survey—The Iowa Tuberculosis Association will conduct a survey in Des Moines as a public health professional project of the Federal Emergency Relief Administration. The work will include the investigation of the physical condition of the families and contacts of the 287 persons who have died of tuberculosis in the city during the past five years. This will cover tuberculin testing, physical examinations and x-ray films of all the contacts who give a positive reaction to tuberculin. Modest fees will be paid for this work to members of the society who cooperate.

Twin Lakes District Meeting—The thirteenth annual assembly of the Twin Lakes District Medical Society will be a diagnostic clinic at Burns' Alhambra Pavilion, Twin Lakes, Rockwell City, June 25. Dr. William M. Shipley, Ottosen, will open the program, and an address by Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, will precede the clinics. His subject will be "Our Changing Times." Physicians presenting clinics will be:

Frederick A. Williams, head of section on cardiology, Mayo Clinic, Rochester, Minn.
Herman L. Kretschmer, Chicago, clinical professor of genito-urinary surgery, Rush Medical College.
LeRoy A. Calkins, professor of obstetrics and gynecology, University of Kansas School of Medicine, Kansas City.
Solon Marx White, professor of medicine, University of Minnesota Medical School, Minneapolis.
Karl A. Meyer, associate professor of surgery, Northwestern University Medical School, Chicago.

The county medical societies of Calhoun, Carroll, Greene, Hamilton, Humboldt, Ida Sac, Kossuth, Pocahontas, Webster and Wright, forming the Twin Lakes District Medical Society, are affiliated for graduate clinical instruction.

KANSAS

Honorary Membership—The Sedgwick County Medical Society held a special meeting, April 19 in Wichita, to honor several of its members who had completed fifty years in the practice of medicine. With the inscription, "In recognition of a half century of faithful service to humanity" the specially engraved certificates of honorary membership were presented to the following physicians:

David W. Basham, Wichita
Henry W. West, Yates Center
Horace G. Welsh, Hutchinson
Casius Clay Surber, Independence
Alexander C. Flack, Fredonia
Frank M. Wiley, Fredonia
Frank G. Emerson, Wellington
Theophilus E. Hinshaw, Winfield
John T. Axtell, Newton
R. C. Hutchinson, Elk Falls
Gideon P. Marner, Marion
Solomon T. Shelly, Mulvane

Thomas J. Hollingsworth, South Haven
Powhatan P. Trueheart, Sterling
Eugene Pile, Ashton
John H. Fuller, Wichita
Leighton P. Ravenscroft, Winfield
William F. Walker, Colwich
Robert C. Splawn, Kincaid
Williston H. Addington, Altoona
Wilburn H. Graves, Wichita
L. L. Ames, Wichita

The speaker of the evening was Dr. Andrew B. Rivers, Rochester, Minn., on diagnosis and treatment of peptic ulcer.

MAINE

Society News—Dr. Seth M. Miliken, New York, discussed "Traction in the Treatment of Fractures" before the Cumberland County Medical Society, April 26.—At a meeting of the Hancock County Medical Society in Ellsworth April 8, Clarence Cook Little, D.Sc., Bar Harbor, spoke on "Cancer Research".—Dr. Francis M. Rackemann, Boston, among others, addressed the Kennebec County Medical Association at Waterville, April 18, on "Progress in Allergy, Asthma and Eczema".—The York County Medical Society at a meeting in Kittery, April 3, heard a discussion on birth control by Dr. Edwin W. Gehring, Portland.

MARYLAND

Bequest for Research Laboratory—Dr. Frank C. Bressler bequeathed \$1,000,000 to the Medical School of the University of Maryland to erect and equip a research laboratory. He also provided for a gift of \$2,500 to the Medical and Surgical Faculty of Maryland, to be known as "The Bressler Fund". Dr. Bressler died May 18.

Personal—Herbert Spencer Jennings, S.D., professor of zoology, Johns Hopkins University, Baltimore, has been named Eastman professor at Oxford, England, for the academic year 1935-1936.—St. Johns College, Annapolis, conferred the honorary degree of doctor of letters on Raymond Pearl, Ph.D., professor of biology, Johns Hopkins University School of Hygiene and Public Health at its commencement June 5.—Dr. John M. T. Finney, professor emeritus of surgery, Johns Hopkins University School of Medicine, Baltimore, has been awarded the honorary degree of doctor of laws by Tulane University, New Orleans.

Dr. Eastman Appointed Professor of Obstetrics—Dr. Nicholson J. Eastman, professor of gynecology and obstetrics at Peiping Union Medical College, has been appointed professor of obstetrics at Johns Hopkins University School of Medicine and obstetrician-in-chief at Johns Hopkins Hospital. He succeeds Dr. J. Whitridge Williams, who, until his death in 1931, had held the position since 1899. Dr. John M. Berglund has been acting professor of obstetrics and acting director of the department. Dr. Eastman graduated from the Indiana University School of Medicine in 1921. In 1924 he was named associate in obstetrics and gynecology at Peiping Union Medical College, returning in 1927 to become instructor in obstetrics at Johns Hopkins. In 1929 he was appointed associate, returning to the Peiping staff in 1933.

MASSACHUSETTS

Dr. Mallory Awarded Medal—The Association of American Physicians conferred the Kober Medal for 1935 on Dr. Frank B. Mallory, eminent professor of pathology, Harvard Medical School, Boston, at its recent annual meeting in Atlantic City. The medal is provided by the George M. Kober Foundation of Georgetown University School of Medicine, Washington, D. C., which was created in 1923 by the late Dr. George M. Kober, former dean of the school.

Dr. Bock Made Professor of Hygiene—Dr. Arlie V. Bock, associate professor of medicine, Harvard University Medical School, Boston, has been appointed Oliver professor of hygiene at the school, succeeding Dr. Alfred Worcester, resigned. Dr. Worcester, who has held the professorship since 1925, was entertained by friends at the Harvard Club April 17. Dr. Roger I. Lee was toastmaster; the speakers included

Dr. Doughty O'Hara, Dr. Reginald Fitz and Mr. W. J. Bingham, director of athletics at Harvard. Dr. Bock is an alumnus of Harvard, class of 1915.

Drs. Minot and Murphy Awarded Medals—The gold medal of the Humane Society of the Commonwealth of Massachusetts has been awarded to Drs. George R. Minot and William P. Murphy, Boston, in recognition of their well known discoveries in the treatment of pernicious anemia. Dr. Charles P. Curtis, president of the society, made the presentation at the Peter Bent Brigham Hospital, May 23. The bestowal of the medal to the physicians marks a change in the policy of the society, which for 150 years has awarded the medal for heroic rescues in which the life of the rescuer was at stake. Dr. Minot is professor of medicine at Harvard Medical School, and Dr. Murphy, instructor in medicine. In 1930 they shared the Cameron Prize of the University of Edinburgh, and in 1934 they with Dr. George H. Whipple, Rochester, N. Y., were awarded the Nobel Prize in Medicine.

MICHIGAN

Hospital News—A new state tuberculosis sanatorium is to be erected at Gaylord with \$250,000 from malt tax funds, in accordance with a law passed by the 1933 legislature. The law provided that the money should be set aside by the state treasurer on March 31, 1935, and construction started immediately. The state department of health has already approved the site.

Veteran Physicians Honored—The three oldest living alumni of the Detroit College of Medicine were presented with gold badges at a dinner in Detroit, May 11, under the auspices of the Wayne University Alumni Association. Drs. Arthur M. Hume, Owosso, class of 1881, Charles G. Jennings, Detroit, class of 1879, and John A. Wessinger, Ann Arbor, 1882, were the guests of honor. The dinner was held to organize the new alumni association, which sponsored it.

Society News—Dr. Harry L. Huber, Chicago, discussed "Allergy in Everyday Practice" before the Calhoun County Medical Society, April 1, in Battle Creek.—The annual clinic of the Medical Society of Ingham County was addressed in Lansing May 16 by Drs. Hugo A. Freund, Detroit, on "Cardiac Irregularities", Gershom J. Thompson, Rochester, Minn., "Management of Ureteral Calculus", John Alexander, Ann Arbor, "The Widening Scope of Thoracic Surgery", Frank E. Whitacre, Chicago, "Forceps", and George W. Crile, Cleveland, "Tumors of the Breast".

MISSISSIPPI

State Medical Election—Dr. Harvey F. Garrison, Jackson, was named president-elect of the Mississippi State Medical Association at its annual meeting in Biloxi, May 16, and Dr. James R. Hill, Corinth, was installed as president. Greenville was selected as the place for the next annual meeting May 12-14, 1936.

Society News—Speakers before the Delta Medical Society in Greenwood April 10, included Dr. James R. Garber, Birmingham, Ala., on "Infection in Abortion".—At a meeting of the Issaquena-Sharkey-Warren Counties Medical Society in Vicksburg, April 9, Dr. Hugh H. Johnston, Vicksburg, among others spoke on "Use of Heat in the Treatment of Sinusitis".—The North Mississippi Medical Society was addressed at New Albany, April 17, by Drs. William T. Black, Memphis, Tenn., on "Endocrinology and Its Relation to the Female", Charles M. Murry, Ripley, "Carbuncles of the Lips and Face", and Conley H. Sanford, Memphis, "Treatment of Pneumonia".—At a meeting of the Pontotoc County Medical Society April 2, Dr. James M. Hood, Houlka, discussed bacillary dysentery.

NEW YORK

Dr. W. M. Allen Honored—The Rochester section of the American Chemical Society sponsored a dinner in honor of Dr. Willard M. Allen, assistant in obstetrics and gynecology, University of Rochester School of Medicine and Dentistry, Rochester, at the University Club, May 16, in recognition of his work on the corpus luteum which resulted in the isolation of "Progesterin". Among the speakers were Prof. John Ernest Lansing, head of the chemistry department at Hobart College, Geneva; Walter R. Bloor, Ph.D., professor of biochemistry and pharmacology and associate dean of the University of Rochester School of Medicine and Dentistry; Murray Bartlett, D.D., president, Hobart College, Geneva; and Dr. George W. Corner, professor of anatomy at the medical school, with whom Dr. Allen collaborated in his research work. Dr. Allen's discovery recently won for him the award of \$1,000 by Eli Lilly and Company for outstanding work in biochemistry.

New York City

Drs Globus and Silverstone Awarded Medal—Dr Joseph H Globus, associate neurologist, Mount Sinai Hospital, and his associate, Dr Sidney M Silverstone, a member of the house staff, have been awarded the Lucian Howe Medal in Ophthalmology for their work on the diagnostic value of visual field defects and other ocular disturbances in supratentorial brain tumors. Dr Globus is also associate professor of neuro-anatomy and neuropathology at New York University, University and Bellevue Hospital Medical College. The prize is awarded by the Medical Society of the State of New York.

Society News—Dr Paul K. Sauer addressed the New York Surgical Society, April 24, on "Carcinoma Following Gastric and Duodenal Ulcer."—Drs Joseph W Larimore, St Louis, and Moses Paulson, Baltimore, addressed the National Society for the Advancement of Gastro-Enterology, April 24 on "The Significance of Gastritis" and "So-Called Nonspecific Ulcerative Colitis," respectively.—Dr James C Healy, Boston discussed "Allergy and Endocrinopathy. Their Medico-Dental Relationships" before the American Stomatological Association, May 27.—The East New York Medical Society celebrated its twenty-fifth anniversary, recently, with a dinner at which all twenty-five past presidents were present. Dr Samuel L Siegler was toastmaster. Speakers included Drs Harry Apfel, first president, who reviewed the society's history and John Sturdivant Read.—Dr Lionel S Auster presented a paper on "Tumors of the Male Breast," with analysis of fifty cases, before the surgical section of the New York Academy of Medicine, May 3.

Dr Flexner to Retire from Rockefeller Institute—Dr Simon Flexner, director of the laboratories of the Rockefeller Institute for Medical Research since the opening of the institute in 1903, has presented his resignation to take effect on the appointment of his successor. Dr Flexner is 72 years of age. He graduated from the University of Louisville (Ky.) School of Medicine. From 1895 to 1898 he was associate professor of pathology at Johns Hopkins University School of Medicine, where for the year ended 1899 he was professor of pathologic anatomy. Following four years as professor of pathology at the University of Pennsylvania School of Medicine, he was named director of laboratories of the Rockefeller Institute for Medical Research. Dr Flexner has contributed extensively to the literature on bacteriology and pathology, especially on epidemic cerebrospinal meningitis and its serum treatment, poliomyelitis, its cause and mode of transmission, and epidemic encephalitis. He, with his collaborators, was the first to use the meningococcus antitoxin. He was chairman of the U S Plague Commission in 1900, a lieutenant colonel in the medical corps of the U S Army from 1917, and in 1919 became a colonel and assistant surgeon general of the U S Public Health Service. In 1923 he was chairman of the Public Health Council of New York.

OHIO

Personal—Dr Edgar R. Hiatt, Troy, was chosen president of the Ohio Public Health Association at its annual meeting in Columbus.

Student Prizes—The senior prize in surgery at Western Reserve University School of Medicine, Cleveland, was presented to Carl Bernard Lechner, Erie, Pa. It consists of books and surgical papers of the late Dr William Stewart Halsted, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, and is the annual gift of Dr Elliott C Cutler, Boston, formerly professor of surgery at Western Reserve. The senior prize in obstetrics was awarded to Edwin Alonzo Lawrence, Norwalk. The prize is the income from a fund given by Dr Edwin C Garvin, a graduate of Western Reserve, class of 1894.

PENNSYLVANIA

Personal—Charles Nelson Fry, Harrisburg, an investigator for the state board of medical licensure since 1926, died April 16.—Dr John L Mansuy, Ralston, has been appointed health officer of Lycoming County.

Physicians Stage Show to Help Hospital—Members of the McKeesport Academy of Medicine presented 'Ye Doctors Minstrels' at the Memorial Theater, McKeesport, May 29. The proceeds of \$2,000 have been turned over to the McKeesport Hospital, to be used for repairs.

Bill Passed—S 1528 has passed the senate, proposing to amend the laws regulating the practice of osteopathy by prohibiting an osteopath from using the title 'Doctor' or the

abbreviation "Dr" before his name without the word 'Osteopath' or "Osteopathist" or the words "Osteopathic Physician" immediately following his name.

Request for New Hospital—A fund of about \$600,000 was recently made available to the University of Pennsylvania from the estate of the late Baroness Margaret Dulles Fontana of Philadelphia. It will be used to build a maternity hospital, which will be named the William Crothers Dulles Hospital in memory of the donor's brother, who lost his life on the *Titanic*.

Philadelphia

Society News—Papers were presented before the Philadelphia Urological Society, May 27, among others, by Drs Walter E Daniel on "Stricture of Urethra in Female" and Collier F Martin, "Lymphopathia Venerea vs Rectal Stricture."—Dr Francis Asliley Taught was chosen president elect of the Philadelphia County Medical Society at its semiannual business meeting May 15.

Memorial to Dr Jarecki—Funds are being solicited to create the Edwin A Jarecki Memorial Research Fund, in honor of the late chief resident physician at the Jewish Hospital, Dr Edwin A Jarecki. The care and disposition of the fund will be in the hands of a board of trustees, consisting of two members each from the board of directors, the medical staff and the ex-residents' association. From time to time the interest will be used as grants to qualified members of the medical staff and ex-resident physicians, to investigate approved scientific research problems. Checks made payable to "The Edwin A Jarecki Memorial Fund" should be sent to Mr Alfred Mayer, administrator, Jewish Hospital.

VIRGINIA

Portrait Unveiled—A portrait of the late Dr G Paul La Roque, professor and head of the department of clinical surgery, Medical College of Virginia, was unveiled at the school May 28, by Laura May Wood, grandniece of Mrs La Roque. Dr La Roque died in 1934.

Child Conservation Committee—A number of child hygiene and child welfare committees of state organizations met in Richmond April 3, to form the State Child Conservation Committee. The agencies represented in the new group and their chairmen follow:

Medical Society of Virginia Dr Waddie P Jackson, Roanoke
Virginia Tuberculosis Association Dr Dean B Cole, Richmond
Virginia Pediatric Society Dr James B Stone, Richmond
Cooperative Education Association Virginia Parents and Teachers, Miss Ellen H Smith
Virginia Education Association Mr J M Shue
State Superintendents' Association Mr W A Scarborough

Changes in Health Officers—Dr Jack B Porterfield has been appointed health officer of Montgomery County with headquarters at Christiansburg. Dr Linwood Farley, Courtland, has been named assistant to Dr Edgar C Harper, Richmond, deputy director of rural health in the Southwest Health District, with headquarters at Abingdon. Dr George E. Waters, formerly of Blackstone, has been appointed acting director of the Peninsula Health District, effective May 6. He succeeds Dr Charles H Dawson, Suffolk, resigned. The district includes the counties of James City, Elizabeth City, Warwick and York, with headquarters at Williamsburg.

Society News—At a meeting of the Postgraduate Medical Society of Southern Virginia and the department of clinical education of the Medical Society of Virginia at Surry, May 7, speakers included Drs Hyman Cantor, Petersburg, on "Acute Perforation of Gastric Ulcer", Rufus L Raiford, Franklin, "Use of Plaster Splints in Treating Fractures," and Andrew Stephens, Graham, Richmond, 'The Colon'.—Dr W Ambrose McGee, Richmond, discussed feeding problems of children before the Southampton County Medical Association recently.—The Roanoke Academy of Medicine was addressed, April 29, among others by Drs William L Powell and Linwood D Keyser on "Polyorchidism with Malignancy in the Supernumerary Testicle".

WYOMING

Personal—Dr Harold E Haymond has been appointed superintendent of the Midwest Hospital, Midwest, succeeding Dr Wilber Hart.

Dr Anderson Named State Health Officer—*Colorado Medicine* announces that Dr George M Anderson, Cheyenne, has taken over the duties of state health officer, secretary of the state board of health and acting secretary of the state board of medical examiners, succeeding Dr Walter H Hassel, Cheyenne. Dr Anderson held the position prior to Dr Hassel's appointment in 1928.

GENERAL

Grants of National Research Council—The Division of Medical Sciences of the National Research Council will hold a special meeting next November to consider applications for grants in this field. Applications to be considered at this meeting must be on file with the secretary of the committee, Dr. Clarence J. West, 2101 Constitution Avenue, Washington, D. C., not later than Oct. 1, 1935. Applications received after October 1 and prior to Feb. 15, 1936, will be acted on at the next regular meeting of the committee on grants-in-aid in March 1936.

Association for the Advancement of Science—The ninety-sixth meeting of the American Association for the Advancement of Science will be held in Minneapolis, June 24-29. At this meeting, special joint sessions have been arranged with the Minnesota State Medical Association, the first of which will be held Monday evening, June 24, with Dr. William P. Murphy, Boston, as the speaker. Joint sessions of the Section on Medical Sciences and the medical society have been arranged for Monday and Tuesday mornings. According to a preliminary program, speakers will include

Dr. Adolph M. Hanson, Faribault, Minn., Biological Effect of Thymus and Pineal Extracts
Dr. Max Cutler, Chicago, Recent Advances in the Treatment of Cancer
Dr. Elmer L. Sevringhaus, Madison, Wis., Endocrine Therapy
Dr. Everett D. Plass, Iowa City, Simplification of Obstetrical Care

In addition, there will be various exhibits concerning cancer, prevention of deafness, mental health, physical therapy, tuberculosis and the endocrines, including one on diabetes mellitus.

Twenty-One Broadcasting Stations Cited to Appear—Because they carried the advertising of a medical preparation which other agencies of the federal government consider improper for use, twenty-one broadcasting stations must appear at a hearing of the federal communications commission, October 3, and show cause why their licenses should not be revoked for failure to operate in the public interest. This action is part of the campaign against radio advertising which has just been launched by the federal communications commission, newspapers announced, May 23. In response to questions by broadcasters and advertisers, most of which concerned medical products, the commission stated

This question is one which essentially does not concern the commission as the sole responsibility of operating its station in the public interest and according to law is upon the station licensee. If a station licensee is not prudent and intelligent enough to find its sources of information to properly guide it then it is not properly qualified to operate a station in the public interest and according to law.

Station licenses are granted for only six months, and on every application for renewal the commission determines whether or not the station is operating in the public interest. While the commission is concentrating now on drug preparations which it considers improper, it probably will extend the drive to other types of programs which it believes "not in the public interest." The twenty-one stations cited are all charged with advertising a reducing preparation which the food and drug administration, federal trade commission and post office department have condemned and tried to put out of business but which, in one way or another, has evaded other federal laws.

Government Services

Federal Narcotic Farm Dedicated

The first United States Narcotic Farm, near Lexington, Ky., was dedicated, May 25. Surg. Gen. Hugh S. Cumming, U. S. Public Health Service, gave the address. Accommodating a maximum of 1,000 persons, the narcotic farm is designed for males only. Its objects and purposes are to rehabilitate, restore to health and train to be self-supporting and self-reliant those who are admitted. In addition, experiments will be carried on to determine the best methods of research and treatment in this field with the ultimate view that states may adopt some similar means to help solve the problem of drug addiction. According to the *New York Times*, four classes of narcotic addicts are to be received. Those convicted of violating federal laws, convicted persons who have completed their prison sentences, offenders on probation and voluntary patients. The plant which required three years to build at a cost of \$4,000,000, occupies eleven acres in the middle of a rich farm area. Staffed by 350 employees, upkeep of the farm is estimated at \$750,000 a year. A similar institution is now being erected at Fort Worth, Texas. (THE JOURNAL, February 16, p. 574)

The Centenary of Hugh Owen Thomas

The centenary of the birth of Hugh Owen Thomas has been celebrated by the publication of a study by Mr. Frederick Watson, son-in-law of Sir Robert Jones. The *Liverpool Medico-Chirurgical Journal* has now produced a centenary number containing a brilliant centenary lecture by Mr. T. P. McMurray, director of orthopedics, Liverpool University. This journal is the organ of the Liverpool Medical Institution, of which Thomas was a member. With the exception of Keith's chapter, "Menders of the Maimed," McMurray's lecture is the first adequate recognition in this country of the genius of the man who laid the foundation of the modern treatment of bone and joint lesions and on whose work is based the structure of orthopedic surgery. Descended from a line of Welsh bone setters, he saw in his father's house many cases of joint disease treated with apparent success. When a medical student at Edinburgh and London, he was convinced that the wholesale amputations then in vogue were unnecessary. He began practice in Liverpool in 1859, and became medical officer to many workmen's clubs—shipwrights, iron workers, boiler makers—which gave him great experience in bone and joint injuries. By his sagacity and mechanical genius he was able to cope with problems which then seemed insoluble. He had his own workshop, where he made with his own hands the splints which have immortalized his name. For thirty years he practiced at high pressure, mainly among the working classes, treating by his own methods all sorts of bone and joint injuries and diseases. His epoch-making advances were ignored by the orthopedic surgeons of the day, and when he died in 1891 the obituaries in the medical journals showed no recognition of the greatness of the man.

It was toward the end of his life, in 1887, that Dr. John Ridlon arrived. Their dramatic meeting and the ignoring of Thomas's teaching that Ridlon found in England have been described (THE JOURNAL, March 23, p. 1018). Although Ridlon was not the first to discover Thomas, he was the first American to do so, and he is now the only living orthopedic surgeon who knew him. There is no more eloquent tribute than Ridlon's, which Mr. McMurray quotes. "Thomas did more good new things for orthopedic surgery than all the rest from Hippocrates down to this day. Today he is known for his leg splint and not for the principles which he laid down, but he was the greatest man in orthopedic surgery for all time." Yet now, more than 40 years after his death, his greatness is far from generally appreciated in England, and outside Liverpool the centenary is almost unnoticed!

When Dr. Ridlon visited the clinics of the orthopedic surgeons he found that not one of them had a good word to say of Thomas, though comparison of their work with his showed that "one could gain more useful knowledge following Thomas around for an hour than elsewhere in Great Britain for months." This neglect can be explained. His bone-setting ancestry aroused prejudice, and he had no hospital appointment, a thing generally regarded as essential for surgical status. Moreover, he reveled in polemics, was no respecter of persons and treated the errors of those in high places with the scorn that was deserved.

Years before Dr. Ridlon came on the scene another meeting of great importance for Thomas's reputation occurred. In 1875 he had under his care a police inspector for compound fracture of the tibia. The limb was fixed in his splint and the whole

apparatus slung on a crane, so as to allow movement of the patient without interfering with the fracture. Dr E Parker, the police surgeon of Liverpool, was instructed to examine the man and brought with him his son Rushton Parker, who had lately come to Liverpool from University College, London, where he was a favorite pupil of Erichsen. He later became professor of surgery in the University of Liverpool. Thomas showed them all the details of his treatment and they at once realized that here indeed was a master. He then took Rushton Parker to his private hospital and showed him several cases of diseased joints that he was treating by his new method of prolonged rest. The meeting led to a life-long friendship. Parker immediately became an enthusiastic disciple, introducing Thomas's methods to the various hospitals to which he was attached and never lost an opportunity of stimulating the interest of the profession in Thomas's work. He also urged Thomas to publish his methods, as otherwise they would soon be claimed by others. Hence in the same year appeared "Diseases of the Hip, Knee and Ankle Joints" which twelve years later brought Dr Ridlon to Thomas. Thus the credit of discovering Thomas belongs to the later Prof Rushton Parker. In the 1885 edition of Erichsen's "Surgery" the leading text book of the day, Thomas's methods receive due recognition. This exception to the general neglect can be explained by Parker's connection with Erichsen. Another leading surgical author, Thomas Bryant of Guy's Hospital also recognized his work. But otherwise up to his death in 1891 his teaching was largely ignored. Then his nephew and pupil Sir Robert Jones, who had the advantage of hospital appointments built on the foundations laid by Thomas and convinced the surgeons of the world of the value of his principles.

What was the kernel of Thomas's doctrine which revolutionized orthopedic surgery? He wrote "Most of our surgery is too mechanical, our medical practice too chemical, and there is a hankering to interfere, which thwarts the inherent tendency to recovery." He held that the surgeon could give aid by giving rest. But the surgeons of his day did not understand how to give rest. Their methods of immobilization were inferior to his and produced injurious compression of the diseased parts. He secured complete immobilization and at the same time avoided all pressure on the diseased parts. His splints are equally serviceable in the treatment of fractures. In his book on fractures, Major Maurice Sinclair described Thomas's splints as "the greatest advance in the treatment of fractures in modern times" and as "instruments so perfect that all modifications do but reduce their efficacy." Their use on the battlefield for the immobilization of gunshot fractures of the femur were taught again by Jones and Sinclair and greatly reduced the high mortality.

The British Postgraduate Medical School

London has no fewer than twelve undergraduate medical schools, each with its own large general hospital, other general voluntary hospitals, several hospitals devoted to specialties, and finally the municipal hospitals, now controlled by the county council, which contain 30,000 beds. The hospitals that are medical schools are preoccupied with undergraduate teaching. This is unfortunate, because it is in them that the most famous teachers work. Two general hospitals are devoted to postgraduate teaching, which otherwise is organized by the Postgraduate Medical Association in a few general hospitals and a large number of special hospitals scattered over London. The want of a central school for postgraduate teaching has long been felt, and its formation has been described in previous letters. It was a great undertaking accomplished by the financial cooperation of the University of London, the government and the London County Council. The last has adapted for the purpose one of its municipal hospitals, the Hammersmith

Hospital. The school has been normally opened by the king. Addressing him, Sir Austen Chamberlain, chairman of the governing body, said that the school had three great tasks: (1) to enable physicians in general practice to learn the latest development in diagnosis and treatment, (2) to provide instruction for graduates desiring to pursue special studies, and (3) to advance medical knowledge. Their ambition was to make the school a great imperial center of British medical science, drawing teachers and students from all parts of the dominions.

Child Guidance

The Child Guidance Council was established to encourage skilled treatment for children showing behavior disturbances and early symptoms of nervous disorder. The council maintains contact between the various clinics throughout the country and arranges the interchange of information and discussion so that the greatest values may be gained from variety of experience. The work has been made possible by the Commonwealth Fund of America, which has financed the undertaking since its inception and which has for many years been financing similar clinics in the United States. At the annual general meeting of the council Dr William Moodie, general secretary, said that the demands of the clinics were increasing in consequence of the increasing realization that mental disorder of all kinds manifested itself in childhood as a primitive thing, and a thing which grew and developed until the adult was afflicted. In thirteen clinics in England and Scotland last year 3,800 cases were treated and about one half did well. Mr Barry C. Smith, general director of the Commonwealth Fund, said that it was a great satisfaction to say that they had received an adequate return for their investment. If an amalgamation between the Child Guidance Clinic and the National Council for Mental Hygiene were effected he would recommend a grant of \$25,000 a year for five years.

Maternal Mortality

The failure to diminish the maternal mortality has led some authorities to suggest that the practice of obstetrics should be under the direction of specialists and not of general practitioners. In the *Lancet* Mr Fardley Holland, obstetric and gynecologic surgeon at London Hospital, states that a striking change in the last fifteen or twenty years is the widening of the indications for intervention during labor. This has occurred in spite of the efforts to prevent it by teachers and textbooks. He considers that the factors which have led to this are (1) the increasing use of analgesics and anesthetics and the building of hundreds of small hospitals where local practitioners, who may have neither the requisite judgment nor skill, have the opportunity to perform cesarean sections and other obstetric operations. The former have increased in an astonishing manner. He quotes a government report on maternal mortality in which it is suggested "that in some cases there may be a tendency to resort to cesarean section without due consideration of other methods." The manufacturing town of Rochdale in Lancashire has a maternal mortality of 10 per thousand. An investigation by the health officer suggested that a large proportion of the deaths was due to too frequent intervention. A movement of reform was set on foot in which the physicians willingly joined. The women were taught to make the fullest use of antepartum clinics. The result was remarkable: the mortality at once fell to 3.9, which is about the average for the country generally. Mr Holland advocates postgraduate training in obstetrics for those who intend to practice this branch.

At the National Conference of Labor Women a resolution was passed urging the Ministry of Health to continue inquiry into maternal deaths and to institute inquiry into maternal morbidity, the adequacy of obstetric training and the relation of nutrition to healthy pregnancy and healthy motherhood.

The Epidemic of Malaria in Ceylon

The malaria epidemic in Ceylon has been described in previous letters. The total deaths in the four months November-February amounted to 54,000. Lieut-Col C. A. Gill, who has made a special study of epidemics as director of public health in the Punjab, was selected to direct the campaign against malaria in Ceylon, for which the state council has set aside \$1,000,000. He has now arrived and states that with the exception of the malaria epidemic in Mauritius in 1867 he has never heard of an epidemic of the magnitude of that in Ceylon.

Professional Secrecy and Police Investigation

Some discussion has arisen as to the information a physician should give when questioned by the police in the investigation of crime. On the one hand it is argued that the physician as a citizen has obligations to prevent the commission of crime or to help in the discovery of criminals, while on the other hand his obligation of professional secrecy is urged. Because of inquiries recently made in connection with a crime by the chief constable of Hove, the local division of the British Medical Association applied for advice. The chairman of the Central Ethical Committee sent the following considered statement which has received the approval of the council of the association: "A request by the police to a member of the medical profession to give the names and addresses of any patients who had consulted him for symptoms particularized by the police ought to be declined, on the ground that to accede to such a request would be a gross breach of professional confidence and might involve him in an action for damages by the patient or patients concerned."

Making Roads Safe for Children

A committee on road safety for school children has been appointed by the government. In the evidence submitted was a memorandum of the Pedestrians' Association, which pointed out that the problem of the reduction of accidents to children could not be considered apart from the general one of road danger. In rural districts the dangers to children occurred mostly when they were walking along roads unprovided with footpaths. These should be provided on the roads used by rural children in going to school. In urban districts most children were killed in going to or coming from school, parks and recreation grounds, and in playing in the streets where no parks or playing grounds were available. No mechanical means of safeguarding pedestrians across roads inspired the same confidence or provided the same safety for children as was afforded by policemen. Therefore traffic duty men should be furnished during the hours of school going and leaving at points where children had to cross main roads. Parents must recognize their direct responsibility for the safety of children up to the age of 3. But the prime responsibility for their safety lay with the motorist, who should drive with a sufficient reserve of control to avoid most of the accidents due to the actions of children.

Two headmasters also gave evidence. They emphasized the need for work in the cultivation of road sense, for the use of street plans marked out in hall or playground, and for practice in road crossing with toy vehicles to represent traffic. Elder children could be instructed in the highway code by simple dramatization of the work of drivers, whose point of view they should be made to see. Drivers might assume that adults possessed road sense, but they had no right to assume that children did.

THE SAFETY OF CYCLISTS

The Cyclist Touring Club presented a memorandum stating that the problem of the safety of cyclists as a whole might be approached from the standpoints of the provision of separate tracks for the voluntary or compulsory use of cyclists the

exclusion of cyclists from certain roads, and stringent precautions to ensure the safety of all road users. The club maintained that the provision of cycle tracks would not be an effective remedy. The exclusion of cyclists from busy streets would probably prevent school children from riding to school except in country districts. Whatever the circumstances in which child cyclists met their deaths, the remedy was training in the wise use of roads and stringent measures against drivers who endangered the lives of others.

The Prevalence of Dental Disease

Civilization and a healthy set of teeth seem to have become incompatible. New headquarters of the British Dental Association have been opened by Mr. Geoffrey Hithersay, Shakespeare parliamentary secretary to the ministry of health. He said that in the last twenty or thirty years science had recognized the vital connection between dentistry and the health of the nation. An effort was being made to see that the care of the teeth and mouth played its proper part in the life of the individual from the earliest stages. Examinations started in the maternity and child welfare centers and went on to the school medical service. Out of some 3,000,000 children examined last year 60 per cent were defective in teeth and needed treatment. There was then a bad gap for the adolescent received no treatment from the state and often failed to obtain any. Then came national health insurance. Since 1921, when dental treatment became an additional benefit, \$100,000,000 had been spent by the lodges in dental treatment. As the financial resources of the country improved he had no doubt that the dental service would be enlarged. He then opened the Robert Lindsay Library, which is claimed to be as good as any dental library in the world.

Why Tuberculosis Prophylaxis Is Sometimes Unsuccessful

Lesne and Dreyfus-See, in a paper read at the April 9 meeting of the Academy of Medicine, state that not infrequently tuberculosis is found in school children in whose families one fails to find any source of infection. A survey of possible loopholes through which children may be infected in the school itself reveals the fact that an inspection must be thorough enough to include the teachers and other personnel of every educational institution. In Paris, teachers are subjected to examination only when they are applicants. In the suburban territory around Paris, such an examination is seldom carried out. To protect school children from possible sources of infection in the form of tuberculous teachers and other personnel, the suggestion is made that the examination of the latter should be obligatory at regular intervals. Furthermore, a systematic search for tuberculosis must be extended to crèches, which has not been the case in the past. Both infants and nursing personnel must be subjected to routine examinations in such crèches.

Lymphatism in Infancy

In the July 1934 issue of *Le nourrisson* Professor Marfan of Paris defines lymphatism as a clinical entity occurring during infancy and characterized by a more or less generalized persistent hyperplasia of the lymph nodes and lymphoid tissues. It is due to the nonspecific reactions in organs and tissues following the majority of prolonged infections and intoxications. It manifests itself by a polyadenitis involving most commonly the cervical axillary and inguinal, less frequently those of the occipital thoracic subaxillary and epitrochlear lymph nodes. This polyadenitis is often accompanied by a slight anemia. In

some cases there is, in addition, a hypertrophy of the tonsils and pharyngeal lymphoid tissue, less often an enlargement of the spleen and thymus in children below the age of 3 years. In 85 per cent the polyadenitis is associated with rachitic (bony) deformities, which has led some pediatricians to term the condition an "osteolymphatism." At necropsy it is not uncommon to find enlarged mediastinal and mesenteric lymph nodes, as well as a hyperplasia of the intestinal lymphoid tissue. Microscopically, one finds in the lymph nodes a cellular and fibrous hyperplasia in variable proportions.

The appearance of these infants is inconstant, some being poorly and others well nourished.

One can divide the cases from the etiologic standpoint into three groups: those in which there has been a mild or severe infection of long standing, those in which there is a dystrophy of alimentary origin and those in which there are persistent digestive disturbances. The result is a generalized reaction of the lymphatic system. Lymphatism is neither the primary manifestation of "scrofulotuberculosis" or of tuberculosis but is a symptom complex seen only in infancy, which in itself is of no consequence but, when present, should lead to a search for the cause. When the polyadenitis is accompanied by bilateral epitrochlear adenitis, one should look for syphilis, tuberculosis or kala-azar. Chronic splenomegaly associated with polyadenitis should lead one to think especially of syphilis, in northern climates, if such a combination occurs during the first four or five months of life.

The treatment of lymphatism depends on the cause. In addition, one should study the diet of the infant, prescribe an open air life and prescribe heliotherapy or ultraviolet treatments.

Rôle of Vasomotor Nerves in Embolic Pulmonary Infarcts

At the April 6 meeting of the Société de biologie, the results of a series of experiments were reported by Delarue, Justin-Besançon and Bardin. The histologic evolution of experimental lesions, from the period of onset of the embolism up to that of cicatrization of the resultant hemorrhagic infarction of the lung, were studied. Their observations prove that the hemorrhagic infiltration of the pulmonary parenchyma is the result of a sudden well localized dilatation of the capillaries with subsequent thickening of the interalveolar septums and a sero-hemorrhagic exudate into the alveoli themselves. This is the typical finding in animals killed immediately after experimental embolism. A quarter of an hour later, one already finds foci of infarction. At the end of from twenty-four to forty-eight hours the picture is that of a typical infarct, which becomes more and more marked in animals killed from seven to fifteen days after the embolism. One finds the same early changes in animals following unilateral section of the vagus in the carotid region or after unilateral chemical stimulation of the trunk of the cervical sympathetic as after experimental embolic occlusion of the pulmonary vessels.

Pleuropulmonary Embolic Form of Myocardial Infarct

An unusual primary clinical manifestation in a case of infarct of the myocardium was reported at the March 29 meeting of the Société médicale des hôpitaux. A man, aged 57, was admitted complaining of dyspnea and a bloody expectoration. The blood pressure two years previously had been found to be 250 mm of mercury. On two occasions during the interval, marked but transitory dyspnea was noted. Three days before admission, bloody expectoration and severe nonradiating pain over the front of the chest began suddenly. The examination on admission revealed the presence of a pulmonary infarct. The cardiac examination revealed only a regular tachycardia, a gallop rhythm and an accentuation of the second sound at

the base. No friction sound or murmur could be found. About fourteen days later, after a temporary improvement, a marked tachycardia appeared, accompanied by a recurrence of pulmonary infarct symptoms. Death occurred suddenly about four weeks after admission.

The necropsy revealed a bilateral pleural effusion, numerous areas of pulmonary infarcts, absence of any lesions in the pulmonary vessels, an adhesive pericarditis and an extensive relatively recent infarct of the myocardium involving the wall of the right ventricle close to the apex. The latter localization of an infarct can be considered as comparatively rare. None of the characteristic signs of an occlusion of the coronary arteries, such as severe angina and a drop in blood pressure, had been present. The main features of the clinical picture had been those of pleuropulmonary infarcts not due to any embolic process.

Paroxysmal Hypertension

The Nov. 16 and 23, 1934, meetings of the Société médicale des hôpitaux de Paris were devoted to a symposium on paroxysmal hypertension. Abstracts of some of the papers was given in a previous letter. The remainder were of equal interest and are taken up here.

Villaret and associates stated that such a paroxysmal rise of blood pressure is simply a sudden alteration of the physiologic mechanism which regulates, under normal conditions, the equilibrium of arterial tension. This sudden rise is the result of the nervous regulatory apparatus that controls vasoconstriction and epinephrine secretion, being subjected to abnormal stimulation.

Monier-Vinard reported a case in which the blood pressure rose to 270 mm of mercury after the drinking of large quantities of wine and would drop to normal as soon as the patient was abstinent.

De Gennes observed a sudden rise to 300 mm of mercury during a hemorrhage into the bulbar region of the brain.

Laubry and Bernal have noted that during the attacks of paroxysmal hypertension there are usually accompanying renal symptoms (albuminuria, polyuria, casts and, at times, hematuria). They disappear unless the hypertension becomes a permanent one. Necropsy in these cases of paroxysmal hypertension reveals only minimal changes in the renal parenchyma.

Rathery believes that in hypertension the renal changes are secondary, yet the existence of a primary hypertension is not cleared up. There are certain cases of permanent as well as paroxysmal hypertension that are not of renal origin, but on the other hand, there are others with such an origin.

Tzanck divides the cases of paroxysmal hypertension into three groups, so far as their etiology is concerned. Those due to epinephrine, those due to an adrenal neoplasm and those in which various substances such as are used for chemotherapy or proteins give rise to paroxysmal hypertension. One sees reactions similar to paroxysmal hypertension, such as pain, dyspnea, collapse and paroxysmal tachycardia, in anaphylaxis, shock, allergy, intolerance and idiosyncrasy.

Opening of the Gilbert Dispensary for Physical Therapy

The department of physical therapy at the Hotel Dieu, one of the oldest and largest hospitals of Paris, had grown to such an extent since the World War that larger quarters became necessary. A new building has been constructed on the grounds of the hospital. It has been named the Gilbert Dispensary in commemoration of the services rendered by the late Professor Gilbert in developing the application of physical therapy to medical and surgical ailments. The new quarters were opened February 25, in the presence of the minister of public health and other officials. The service is equipped with every known

apparatus for physical therapy In 1934 more than 300 treatments were given in the old quarters, and this number will be greatly augmented when the more adequate facilities offered by the new building come to be utilized. The services include those for radiotherapy, electrotherapy, kinesiotherapy, hydrotherapy and mechanotherapy. The new building is well worth a visit by those interested in physical therapy.

Three Cases of Gangrenous Erysipelas

Lemierre, Brocard and Pham reported three cases of gangrenous erysipelas at the February 22 meeting of the Société médicale des hôpitaux. In two patients the erysipelas involved the lower portion of the thigh, the skin presenting also large phlyctenules. Gangrene occurred on the fifteenth and sixth days respectively of the disease. One of these terminated fatally but, in the other, recovery occurred after extensive involvement of the skin and subcutaneous tissues. In the third case the foot was the seat of the infection, which was accompanied by an extensive gangrene. In the first two cases, cultures revealed the presence of an anaerobic bacillus associated in large numbers with the streptococcus. In the third case there was a large number of streptococci and *Staphylococcus aureus*. The authors believe that this association of organisms is responsible for the gangrene. Examination of the blood failed to reveal a hyperglycemia. Hemocultures were constantly negative. In the fatal case an erysipelas of the face and an alcoholic cirrhosis were undoubtedly the complications that determined the outcome. The only treatment consisted in applications of potassium permanganate solution. The prognosis is, as a rule, not an unfavorable one and should be borne in mind before an amputation is considered.

BERLIN

(From Our Regular Correspondent)

April 15, 1935

Congress of Internal Medicine

The Deutsche Gesellschaft für Innere Medizin convened this year in Wiesbaden March 25-28 under the chairmanship of Professor Schottmüller of Hamburg, who, in his address concerning the medical training of the next generation, demanded that a large portion of the practical training of physicians should be in the field of internal medicine. Dr. Wagner, the federal *führer* of the physicians, emphasized that the new German medicine must be built up on the basis of the national-socialist world views. A bridge must be erected between the knowledge of the old school of medicine and the nature cure methods. The extreme views of both camps must be suppressed.

The first day was devoted to the questions of aeronautic medicine. Schubert of Prague considered the problems of flying at high altitudes on the basis of his own observations. Flying, at heights of from 10,000 to 11,000 meters, is exceedingly trying on the mind and nerves. In addition, respiration and circulation are overburdened by the atmospheric conditions, radiations, lowered oxygen tension and other factors. It should be adopted as a principle that from 4,000 meters on, artificial oxygen should be administered. Modern airplanes especially adapted for flying at high altitudes require great elasticity of the circulation. Only aviators from 20 to 30 years of age should be selected for high flying. In record flights to altitudes up to 14,000 meters, the capacity for action and reaction, even with the use of artificial oxygen, is so limited that the aviator is unable at such heights to make quick decisions, which is essential. An altitude of 10,000 meters must be regarded, therefore, as the upper limit of safety. The addition of carbon dioxide to oxygen, as proposed for example, by the French (2 per cent) and by the Italians (8 per cent) rests, according to Schubert on an erroneous theory and, from a practical point of view, is unnecessary.

Diringshofen of Berlin spoke, with especial consideration of the effects of acceleration, on the basis of his own observations in flying at high altitudes. In addition to the effects mentioned by Schubert, attention should be given to the expansion of the intestinal gases, which, under certain circumstances, may lead to upward displacement of the diaphragm. At an altitude of only 1,000 meters, the increase of the volume is 12 per cent, at 5,000 meters 100 per cent, and at 10,000 meters 400 per cent. Since the total amount of intestinal gas may be assumed to be normally no more than 1 liter, the increased volume in ordinary flights offers no danger. Air sickness is of labyrinthine origin and is identical with seasickness. Other injuries, caused by breathing oil vapors and exhaust gases, may be overcome by technical refinements. Great importance attaches to the effects of rapid accelerations. In precipitate descents and in the rounding of curves, forces act on the body that may be equal to five times the body weight, and serious disturbances can be avoided only if the pressure is applied but a few seconds—ten at the most, otherwise disturbances, particularly of vision, together with loss of consciousness, are likely to occur. The pressure on the circulation from without must be compensated for by a timely increase of the blood pressure, if disturbances are to be avoided. Thus, voluntary increases in the blood pressure can be effected by increasing the abdominal muscular pressure, or by bending the body forward, whereby the difference between the height of the heart and the height of the head is lessened, also by the intensive application of will power and keeping up uniform breathing. In this manner it is possible to endure strong accelerations for several seconds without any disturbance. In flying on one's back the conditions are reversed, in this position injuries to health are caused by venous stasis (retinal hemorrhages, also cerebral hemorrhages).

In the aptitude for flying, as Lottig of Hamburg pointed out, the whole personality plays an important part. A mechanistic estimation should be avoided. A slight acceleration of pulse or the like does not constitute a detraction from the fitness of an aviator. The flight surgeon who decides on the fitness of candidates should be a good aviator himself. For flying at high altitudes, candidates, as Hartmann of Berlin pointed out on the basis of the observations of the Himalaya Expedition, in 1931, should be trained gradually in subpressure chambers.

In sport devotees there occurs, as Kirch of Erlangen found, a genuine cardiac hypertrophy, which does not, however, affect ordinarily the whole heart. A disproportionate enlargement is characteristic, the type of enlargement varying with the kind of sport. For example, the right ventricle was hypertrophied in a boxer and the left ventricle in a swimmer, while in a mountain climber the right chamber was more developed than the left. The enlargement was usually in the direction of the longitudinal rather than the horizontal axis. According to Rautmann of Braunschweig, a portion of these changes are doubtless due to the fact that, at least in many sports, inspiration predominates over expiration, so that an increased volume of blood passes through the right side of the heart. It was found that the pulse beat diminished inversely with the length of the distance for which a runner is trained. For instance, long distance runners present when at rest a pulse beat of 60 and below, whereas the pulse beat of sprinters at rest is higher. Hence, the adjustment of the organism to outstanding achievements is accomplished through an increase of the stroke volume and not through an increase of the pulse beat. In the discussion it was emphasized that heart enlargement in sport devotees must not be judged wrongly or in a one-sided manner.

The second main topic, the 'Significance of Gastrosocopy,' was discussed by Gutzeit of Breslau, who demonstrated its practical importance by an analysis of 3,500 cases. Henning

of Leipzig reported that he had examined 2,200 cases, 1,200 with an inflexible and 1,000 with a flexible gastroscope. With the former type gastric hemorrhage resulted in one instance, but with the flexible type no failures occurred. It is not possible in all cases to make the pylorus visible, the principal task of gastroscopy is to supply a clear view of the gastric mucosa. Roentgenology of the stomach does not furnish clear views, gastroscopy is much superior, and with the modern apparatus injuries are no longer possible.

The third topic was "The Acute Blood Disorders of the Myeloid System." Werner Schultz of Berlin discussed in detail agranulocytosis. Owing to inflammatory and necrotic processes occurring in the gastro-intestinal tract, agranulocytosis may be confused with typhoid. The etiology is uncertain, although there is no doubt that the constitution plays a part. The angina is doubtless not the primary thing. The organisms found by the bacteriologist have no etiologic importance. The morbid picture of agranulocytosis should be studied primarily from the standpoint of the symptoms. The most widely different processes, such as pregnancy, tuberculosis of the bone marrow, typhoid, other infections, drugs and toxins may lead to an outbreak of the disorder. On the basis of these facts, arsphenamine should be avoided in Plaut-Vincent's angina, since this benign disorder may be cured without the use of arsphenamine. With reference to the appearance of angina agranulocytica in various countries, neither experimental trials nor clinical observations in Germany have furnished proof of the alleged harmful effects of amidopyrine. The aplastic anemias also play an important role. Degeneration of the bone marrow may sometimes be the primary cause. As for treatment, liver, arsenic and particularly blood transfusions are to be considered rather than roentgen therapy.

On the basis of more than 500 sternal punctures, Naegeli of Zurich expressed the conviction that the bone marrow is of especial importance as the point of origin of these disorders. Neither cadaver blood nor circulating blood will give a clear insight into the situation, since the blood picture of the circulating blood is always under the influence not only of pathologic processes but also of regenerative processes occurring in the body. At the request of the federal bureau of health, V. Schilling of Münster investigated, in connection with agranulocytosis, alleged harmful effects of amidopyrine and barbituric acid preparations. Eighty clinical experiments and ten experiments on rabbits proved entirely negative. An injury of the hematopoietic organs, in the nature of agranulocytosis, could not be brought about by these substances. Schilling's point of view, that it is a question primarily of an exceptional individual reaction, was recognized also in the discussion. The outcome of the discussion was to the effect that, in cases apparently brought on by medicines, it is a question of individual "allergic" reactions. The practitioner, however, should not allow himself to be influenced in the use of approved remedies, since ordinarily no injuries result.

Professor Alfred Goldscheider

Prof. Alfred Goldscheider, who for many years occupied a chair in internal medicine at the University of Berlin, died April 10, at the age of 77. He laid the foundations of his scientific activity as the assistant of Ernst von Leyden, at first devoting himself to the physiology of the nerves. We are indebted to him for our knowledge of atypical gout. In collaboration with his teacher (Leyden), he established the fundamental principles of modern physical therapy. As a university instructor and as a member of learned societies Goldscheider served as a trustworthy champion of the rights, duties and privileges of the medical profession. He was held in high esteem and for many years was president of the Berlin Medical Society, resigning only at the behest of the new regime.

BUCHAREST

Increased Mortality in Bucharest

Public health statistics show that mortality, as well as morbidity, has increased in recent years under the influence of the prevailing economic conditions. When the figures of 1923, 1924 and 1925 are compared with those of 1930, 1931 and 1932, an increase in mortality of 206, 164 and 193, respectively, is found to have occurred in diseases of the nervous system, of 1,680, 976 and 1,094 in pneumonia, of more than 1,000 in diabetes, of more than 1,600 in heart diseases, and of 2,000 in neoplasms. The increase is much more marked in provincial towns, where the increase in pneumonia is ascribed to the reduced resistance of the population, owing to defective nutrition. The increase in circulatory diseases, especially in the rural parts of the kingdom, is put down to defective nutrition and to the psychic factor induced by manifold worries and exhaustion as a sequel to strenuous agricultural work. The price of agricultural products being extremely low, they endeavor to make up for the shortage of income by exertion in working.

Blood Transfusion in Anemia and Infections

At a recent meeting of the Bucharest Medical Society Dr. Antonescu discussed the practice of blood transfusion in sepsis. Blood transfusion is valuable in various forms of anemia and in infectious diseases. To the former, belong anemia resulting from hemorrhage due to injury, child birth, ulcers, shock, hemorrhoids, hemophilia, hemorrhagic diathesis, and the secondary anemias associated with disturbed nutrition and intoxication, pernicious anemia and hemolytic icterus. This list has been compiled by Professor Falta of Vienna. The effects of transfusion in these various diseases are not the same. In severe hemorrhage, transfusion constitutes a substitution therapy, the new blood taking over the function of that which was lost, and in addition it stimulates the hematopoietic areas. Only a few hours afterward reticulocytes appear in the blood. In infections and sepsis, transfusion promotes the production of blood corpuscles and the formation of immune bodies in the reticulo-endothelial system, which in severe sepsis is especially important because the whole system is flooded with bacteria and may be seriously damaged by the endotoxins, whereby its phagocytic and immunizing activity is impaired. The intake of healthy bacteria-free blood cleanses the system and restores its function. In most of the Bucharest clinics the direct method of blood transfusion is most commonly employed, the citrate method is less and less used.

A Disastrous Error in Prescribing Thallium Acetate

A regrettable example of an error in writing prescriptions occurred in Budapest. A professor of the agricultural high school in Czegeld consulted Dr. Dezso Steiger Kazal, a lecturer on dermatology at the University of Budapest, for a fungous scalp disease from which his twin sons of 9 years suffered. Dr. Kazal, having had experience with thallium preparations in similar cases, prescribed this drug, but in error he wrote 50 Gm. instead of 0.5 Gm. The pharmacist, having seen that the prescribed dose was far above the maximal dose, hesitated to dispense it, but seeing the physician's signature thought that he intended to dispense the quantity among several patients, so he gave out the drug, as prescribed by the Hungarian pharmaceutical law in a hexagonal bottle, meaning that the drug is for external use only. Dr. Kazal himself administered the drug with the result that both children died in five days. The police demanded a necropsy which revealed that the cause of death was an overdose of thallium. As the children weighed 30 Kg. each should have been given 24 centigrams, that is 48 centigrams 0.5 Gm. for the two.

Scoliosis Among School Children

Addressing recently the Société belge d'orthopédie, Dr Ledent presented some reflections on scoliosis occurring in pupils of the primary schools. The schools were accused of being the producers of scoliosis, just as their role in the genesis of myopia has been definitely shown. One may incriminate particularly the school furniture, which is often unadapted to the sitting height of the children. But parents who blame the school may fail to check up on the home furniture, especially the chairs. They may fail to note the discordant height of the table, at which a younger child sits uncomfortably suspended, while a tall youth bends over, thus accentuating a tendency to kyphosis or scoliosis.

Deviations of the vertebrae (anomalies, deformations and awkward attitudes) are frequent. The most recent researches are those of Strugurescu, who examined 2,640 children of all ages, and the inquiry of Szczygiat in Poznan. The speaker compared the results of their researches with data derived from his annual inspection of 1,000 children aged from 12 to 16 years (boys and girls), and he obtained about the same percentages as they

School Year	Boys	Girls
1932-1933	5%	30%
1933-1934	7%	20%

To be sure, it is not the duty of the school to treat the children. Nevertheless, the law states that the school owes the child a suitable physical, intellectual and moral education. As regards physical education and orthopedics, it is well known that if a school is properly organized the number of scolioses may be reduced from 20 per cent to 7 per cent. The modern school will no longer be the main source of the orthopedist's patients when physical education receives the same attention as the other subjects of the curriculum.

International Conference on Physical Education

The Société médicale belge d'éducation physique et de sports has organized, for the period from June 30 to July 3, after the plan of the Journées médicales de Bruxelles, an international conference at which the following topics will be discussed: (1) the early detection of cardiac disorders, presented by Laubry of Paris, Samain of Paris, the physician-commandant of Chaise Martin, Joinville, and Van Dooren of Brussels; (2) motor tests in physical education, presented by Professor Laugier of Paris, Covaciu Ulmeanu of Bucharest and Rene Ledent of Liege, and (3) le cyclisme, presented by Professor Hedon of Montpellier, Włodzimierz Missiuro of Warsaw, Brandt of Geneva, and Prof C Heymans of Ghent. The conference will be opened Sunday, June 30, at a formal gathering, at which Prof J Demoor of Brussels will speak on the subject of "The Role of the Physician in Physical Education."

Illegal Practice of Physical Therapy

There are no legal provisions that reserve to doctors the application of physical therapy, which presents sometimes grave dangers when applied by inexperienced persons. There is an urgent need of devising some means of preventing incompetent persons with a limited education or of rudimentary intelligence from exposing the public to the menace resulting from the absence of diagnosis and ignorance of the effects to be produced and the doses to be employed. It would be well if the use of physical therapy in its various forms might be restricted to masseurs and nurses who have received special training and who operate only under the direction of a physician and the terms of a prescription indicating the procedures and the dosage to be employed.

Physical therapeutic procedures present without doubt hidden dangers when sick and weakened organisms are involved, which is especially evident under the conditions that characterize a simple or pernicious anemia, for example, disorders of blood pressure, febrile disorders, or chronic disorders of the kidney, the heart, and of the nervous and the glandular systems. In addition to these cases, which are countless and in which a blind therapy may be harmful, one must emphasize also the danger of incorrect handling of apparatus. In view of these considerations, the Cercle Liegeois de médecine physique et de radiologie contends that a better supervision of masseurs and nurses giving physical therapeutic treatment should be devised.

Antihormones

Dr Thirls Martins, in a lecture before the Sociedade de Biologia of São Paulo, said that the administration of certain hormones for as long as four or five weeks results in a condition of apparent insensibility of the reacting organs. Growth, gonad-stimulative and thyrotropic hormones of the hypophysis when repeatedly injected in animals lose in a short time the stimulative capacity. Hisaw, Collip and some others verified these facts. Collip proved that the serum of horses injected with thyrotropic hormones has protective properties against those hormones. However, hormones can be given for a long time in some cases without any manifestation of the production of antihormones. In the experiments of parabiosis with normal and castrated rats it was verified that in the latter the secretion of prehypophyseal hormones is excessive and the stimulation of the genital organs intense. Even in experiments carried on for more than six months the ovary does not lose its reactive capacity. Since parabiosis is a method more physiologic than the injection of extracts for the administration of hormones, it is advisable to determine whether the antihormones that are observed in experiments are manufactured in their course because of the presence of certain substances that are not secreted by normal glands.

Surgical Treatment of Megacolon

Dr Alípio Correa Netto, in a lecture before the Sociedade de Medicina e Cirurgia of São Paulo, said that the theory of achalasia of the so-called functional sphincters of the colon clarifies the pathogenesis of megacolon. The condition is caused by a dysfunction of the sphincters that fail to open when a wave of peristalsis reaches them. Because of the failure of the sphincters there is fecal stasis, which results in hypertrophy of the walls and dilatation of the colon. The achalasia theory was advanced for the first time as the cause of megacolon by Horste and verified later by Cameron, Amorim, Correa Netto and Etzel. The histologic examination of the colon in this condition shows that the abnormality originates in an inflammatory process, with destruction of the Auerbach and Meissner's plexuses. The condition is cured by the resection of the involved sphincters, which results in the prevention of the presence of fecal stasis and the correction of the abnormality. The speaker presented five patients, in whom the resection of the pelvic rectal sphincter resulted in recovery. The correction of the abnormalities of the colon was evident, as seen by the roentgenograms taken before and after the operation.

Etiology of Trachoma

Dr A. Busacca recently reported, before the Sociedade de Biologia of São Paulo, the results of his work on trachoma. He found rickettsia first in the epithelial cells and in the granular tissues that constitute the trachoma pannus in human beings, by using the method that Jahnke uses for identification of spirochetes in nervous tissues, and then in smears and sec-

tions of trachoma tissues by the method commonly used for identification of rickettsia. The inoculation of trachomatous material in several structures of mice, rabbits and guinea-pigs gave the following results. In the vitreous body of rabbits and guinea-pigs it caused choroidal and retinal lesions in some cases and the appearance of a corneal pannus, similar to human trachomatous pannus, in some other cases, in the testicle of guinea-pigs it caused an inflammation of the polyblastic type transmissible in a series, in the mesothelial cells of the tunica vaginalis of the testicle, micro-organisms similar to those found in human tissues were evidenced, in the brain and spleen of mice, in the brain and testicle of rabbits and in the lymph nodes of guinea-pigs it gave negative results, in the brain of guinea-pigs it caused a slight reaction of the polyblastic type, after some serial passages. Some guinea-pigs developed a general disease following the inoculation of trachomatous material by intracerebral or intratesticular routes. The data obtained by the speaker were not enough to study the appearance of phenomena of immunity.

Avitaminosis in the Etiology of Mega-Esophagus and Megacolon

Dr Eduardo Etzel, in a preliminary report recently read before the Sociedade de Medicina e Cirurgia of São Paulo, stated that mega-esophagus ("mal de engasgo") and megacolon are two abnormalities that frequently coexist with polynuritis, disturbances of the gastric chemism (anachlorhydria and hypochlorhydria) and changes in the electrocardiogram. The latter exist in 70.8 per cent of the cases and are of various types. The speaker said that dysphagia, constipation, polynuritis and disturbances of the gastric chemism and of the heart are also seen in beriberi, both in man and in animals. He presented a case of beriberi associated with "mal de engasgo" and made a reference to other similar cases, as well as to experiments in which he succeeded in producing megacolon in animals with avitaminosis B. The speaker concluded that mega-esophagus and megacolon are the result of a diet deficient in vitamin B. His conclusion is supported by the geographic distribution of "mal de engasgo" and also by the clinical and anatomicopathologic picture of the disease. Further conclusions will be presented by the speaker as soon as his experiments on avitaminosis in pigeons, guinea-pigs and dogs are finished.

Denervation of Adrenal Glands in Hyperthyroidism and Gastroduodenal Ulcer

Dr A. Bernardes de Oliveira, in a preliminary report to the Sociedade de Medicina e Cirurgia of São Paulo, reviewed Crile's theories on the development and management of certain diseases peculiar to civilized men, with especial reference to the genesis of gastroduodenal ulcer and hyperthyroidism. The speaker discussed first the theories on the kinetic system, the law of orthogenesis and the phylogenetic pathology and then the indications, contraindications, technic, risks, complications and immediate and late results of the denervation of the adrenal gland (Crile's operation). He illustrated the technic of the operation and explained the conceptions on which it is based. In two cases of hyperthyroidism, two cases of gastroduodenal ulcer and a case of grave trophic edema of the face the operation, performed by the speaker, gave satisfactory immediate results that confirm those reported by Crile, the originator of the operation.

First Brazilian Congress Against Cancer

The first Brazilian Congress Against Cancer, organized by the Sociedade de Medicina e Cirurgia of Rio de Janeiro, will be held in October at Rio de Janeiro. The members of all the medical societies and medical institutions of Brazil will meet at the congress, which aims to organize a well directed intensified and systematic crusade against cancer.

Marriages

THOMAS S. WHITE, Millbrook, N. Y., to Elizabeth Juanita Greer, Ph.D., of Atlanta, Ga., June 6.

LEWIS H. ODEN JR., Blackshear, Ga., to Miss Agnes Elizabeth Shealy of Clinton, S. C., June 4.

JOHN BRECKENRIDGE OVERALL to Miss Mary Walker, both of Springfield, Ky., May 25.

STEPHEN WEBB DAVIS, Charlotte, N. C., to Miss Kate Jones of Atlanta, Ga., June 8.

JACOB C. ROSEN to Mrs. Iras Marina Schorsch, both of Philadelphia, May 28.

Deaths

William Brodnax Bamister ♂ Colonel, U. S. Army retired Petersburg, Va., Hospital College of Medicine, Louisville, Ky. 1883, entered the army as an assistant surgeon in 1886, promoted to captain and assistant surgeon in 1891, veteran of the Spanish-American War, was promoted to grade of major in 1901 and in 1922 retired, with rank of colonel, at his own request, after thirty years' service, fellow of the American College of Surgeons, aged 73, died, May 1, of coronary thrombosis.

Charles Harper Richardson, Pittsfield, Mass., Albany (N. Y.) Medical College, 1897, member of the Massachusetts Medical Society, fellow of the American College of Surgeons at various times on the staffs of the Hillcrest Hospital and St. Luke's Hospital, Pittsfield, the W. B. Plunkett Memorial Hospital, Adams, the Fairview Hospital, Great Barrington, and the Robert C. Geer Memorial Hospital, Canaan, Conn., aged 65, died, May 21, of carcinoma of the pancreas.

Newton Albert Powell, Toronto, Ont., Canada, M.B., Trinity Medical College, Toronto, in 1875 and M.D. in 1888, Bellevue Hospital Medical College, New York, 1875, professor emeritus of medical jurisprudence, University of Toronto Faculty of Medicine, fellow of the American College of Surgeons, consulting surgeon to the Grace and Toronto General Hospitals and the Toronto Hospital for Incurables, aged 85, died, April 7.

Arthur Ferdinand Fischer ♂ Hancock, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor 1890, fellow of the American College of Surgeons, formerly secretary of the Houghton-Baraga-Keweenaw Counties Medical Society, on the staff of St. Joseph's Hospital, chief surgeon to the Quincy Mining Company, aged 67, died, May 17.

Henry Stanislaus Rowen ♂ Boston, Harvard University Medical School, Boston, 1892, police surgeon, trustee of the Metropolitan State Hospital, Waltham, Mass., for many years on the staff of the Boston Lyng-In Hospital and trustee of the Boston City Hospital, aged 66, on the staff of St. Elizabeth's Hospital, where he died, April 29.

Walter Ford Henderson ♂ Jackson, Miss., Vanderbilt University School of Medicine, Nashville, Tenn., 1916, served during the World War, fellow of the American College of Physicians and member of the Radiological Society of North America, director of the x-ray department of the Baptist Hospital, aged 43, died, April 18.

Clarence Robert Hutchins, Saranac, N. Y., New York University, University and Bellevue Hospital Medical College, 1911, member of the Medical Society of the State of New York since 1917, health officer of the village of Dannemora and since 1916 health officer of Saranac, aged 50, died, March 5, of coronary thrombosis.

Mary Sherwood, Baltimore, Universität Zürich Medizinischen Fakultät, Zürich, Switzerland, 1891, medical director of the Bryn Mawr School, at one time director of the Municipal Bureau of Child Welfare, formerly trustee of the Goucher College, aged 79, died, May 24, at her home in Homeland, of heart disease.

Wallace Joseph Durel ♂ New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1897, professor of clinical medicine, Tulane University Graduate School of Medicine, for many years on the staff of the Charity Hospital, aged 57, died, April 8, of hypertensive heart disease and coronary thrombosis.

Samuel Clarence Dean, Anderson, S. C., Tulane University of Louisiana Medical Department, New Orleans, 1910, member of the South Carolina Medical Association, fellow of the Amer-

ican College of Surgeons, served during the World War on the staff of the Anderson County Hospital aged 51, died May 17

Benjamin Rush Field, Easton, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1883 member of the Medical Society of the State of Pennsylvania, veteran of the Spanish-American War, at one time mayor of Easton, formerly superintendent of the Easton Hospital, aged 73, died, May 1

Clinton Willoughby D'Alemberte, Pensacola Fla Tulane University of Louisiana Medical Department New Orleans 1903, member of the Florida Medical Association, served during the World War for many years connected with the U S Public Health Service, aged 55, died, May 5

Daniel Malloy Prince, Mount Vernon Wash., University of Virginia Department of Medicine, Charlottesville 1924 member of the Washington State Medical Association and the Medical Society of Virginia, on the staff of the Mount Vernon General Hospital, aged 37, died suddenly, April 10

Anthony Curt Freeman, New York Columbia University College of Physicians and Surgeons New York 1910 at various times on the staffs of St Mary's Hospital and the Floating Hospital of St John's Guild, aged 51, died May 23 in Claremont, N H, of carcinoma of the right lung

Lester William Bellows, Waterloo, N Y., Detroit College of Medicine, 1904, past president of the Seneca County Medical Society, aged 56, on the staff of the Waterloo Memorial Hospital, where he died, in May of a skull fracture received in a fall from the porch of his home.

Charles Augustus Kinch, East Orange N J., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1873, aged 83, died April 23 in the Presbyterian Hospital, Newark, following an operation for pyloric obstruction due to duodenal ulcer

Walter Salem Weiss, Jefferson, Ohio, Western Reserve University Medical Department Cleveland, 1888, county health officer, president of the school board of Jefferson, and member and past president of the county board of education aged 71, died, April 22, in Eagle Rock, Calif

George Henry Walter, Orangeburg, S C Medical College of the State of South Carolina, Charleston, 1904, past president of the Orangeburg County Medical Society served during the World War, on the staff of the Tri-County Hospital, aged 56, died, May 12

Albert Marcellus Dawson, West Allis Wis., Kansas Medical College, Medical Department of Washburn College Topeka 1907, member of the Indiana State Medical Association aged 54, died, April 29, in the Deaconess Hospital, Milwaukee, of lobar pneumonia

Mark Henry Williams, New York, University of the City of New York Medical Department 1870 member of the Medical Society of the State of New York, aged 86, died, May 22 in the Wickersham Hospital, of chronic myocarditis and coronary sclerosis

Columbus Fuller Bucklin, Sawyer, Kan College of Physicians and Surgeons, Keokuk Iowa 1896 member of the Kansas Medical Society, aged 66, died, March 16, of diabetes mellitus, hypertrophy of the prostate and rupture of the gall-bladder

Rolfe Spaulding Russell, Greenfield, Mass., University of Vermont College of Medicine, Burlington 1930, member of the Massachusetts Medical Society, aged 28 on the staff of the Franklin County Hospital, where he died, March 17, of embolism

John Ellis Hart, Wadesboro N C University of Maryland School of Medicine, Baltimore, 1897 member of the Medical Society of the State of North Carolina, for many years member of the state legislature, aged 59, died April 7

Robert Emmett Minahan, Green Bay Wis., Rush Medical College, Chicago, 1886 member of the State Medical Society of Wisconsin, also a lawyer, at one time mayor of Green Bay, for many years bank president, aged 77 died, April 27

Eugene Oscar Pearson, Pittsburgh Jefferson Medical College of Philadelphia 1900, member of the Medical Society of the State of Pennsylvania on the staff of St Joseph's Hospital aged 59 died, April 22, of coronary occlusion

Howard J Bush, Constantine, Mich Detroit College of Medicine 1908 on the staff of the Three Rivers (Mich.) Hospital aged 51 died May 2, of pneumonia and coronary and pulmonary thrombosis following an appendectomy

William Walker Evans, Blakely Ga., Atlanta College of Physicians and Surgeons 1902, member of the Medical Association of Georgia past president and secretary of the Screven County Medical Society, aged 58, died, May 10

Reuben Hayes Irish, Troy, N Y., Albany Medical College, 1897, member of the board of managers of the Pawling Sanatorium, Wynantskill, on the staffs of the Leonard and Samaritan hospitals, aged 63, died, April 30

Mary Byington Nicola, Los Angeles, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897 aged 66 died, March 17, in the New England Sanitarium and Hospital Melrose, Mass., of biliary cirrhosis

William Jennings Erkenbeck, Grand View, Idaho, American Medical Missionary College, Chicago 1902, member of the Idaho State Medical Association, aged 55, died, April 15, in the Veterans Administration Facility, Boise

Benjamin Siegel, Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1919 on the staffs of the Israel-Zion Hospital and the Cumberland Hospital, aged 40, died May 17 of cerebral hemorrhage

William Gifford Francis, Waynesville, N C., Jefferson Medical College of Philadelphia, 1915 member of the Medical Society of the State of North Carolina, served during the World War, aged 45, died, May 18

Charles Harold Ainsworth, St Clair, Mich., Detroit College of Medicine and Surgery, 1930, member of the Michigan State Medical Society, aged 32, died, May 13, in St. Clair Community Hospital, of pneumonia

Frederick Stickney Caverly, Passaic, N J., Dartmouth Medical School, Hanover, N H., 1904, on the staffs of the Passaic General and St. Mary's hospitals, aged 52, died, May 15, at his home in Clifton, of heart disease

Grosvenor L T Hayes, Granville, Vt., University of Bishop College Faculty of Medicine, Montreal, Que., Canada 1895, aged 63, died, April 2, in the Royal Victoria Hospital, Montreal, Que., Canada

Joseph Thomas Kennedy, Cincinnati, Medical College of Ohio Cincinnati 1907 served during the World War, connected with the Veterans Administration, aged 50, died, April 30 of lobar pneumonia

Elias Goldberg, Boston, Tufts College Medical School, Boston, 1907, aged 50 died, May 25, as the result of injuries received when he jumped from a stairway window between the ninth and tenth floors

Roger L Hall, Pawhuska Okla., Missouri Medical College, St Louis, 1894, formerly councilman member of the school board and state senator, aged 65, died, April 22 of coronary thrombosis

William Henry Robbins, Martins Ferry, Ohio Jefferson Medical College of Philadelphia, 1916, aged 52, on the staff of the Martins Ferry Hospital, where he died, April 18, following a mastoid operation

Julien Arthur Riester, Buffalo, University of Buffalo school of Medicine, 1899, on the staff of the Buffalo Hospital of the Sisters of Charity, aged 64, died suddenly, April 20, of angina pectoris

Joseph D Orr, Leechburg, Pa., Jefferson Medical College of Philadelphia 1885 aged 77, died April 29, in the Allegheny Valley Hospital, Tarentum, of arteriosclerosis and hypertrophy of the prostate

Solomon E Allgood, Lucas, Kan., Memphis (Tenn.) Hospital Medical College, 1887, University of Louisville (Ky.) Medical Department, 1891, aged 84, died, April 1, of bronchopneumonia

Carl Atkins Foster, Columbia, S C., Medical College of Virginia, Richmond, 1904, member of the South Carolina Medical Association, aged 56, died, May 15, of coronary occlusion

Newton W Amos, St Louis, Washington University School of Medicine, St Louis, 1897, member of the Missouri State Medical Association, aged 67, died, May 6, of angina pectoris

Arthur Cocheran Walker, Springfield Vt., Atlanta Medical College, 1915, member of the Vermont State Medical Society served during the World War, aged 43, died, May 31

William Dibble Clark, Oakland, Calif., University of California Medical Department, 1884, aged 71, died, April 28 of hypertension, chronic myocarditis and hypostatic pneumonia

Frank C Bressler, Baltimore, College of Physicians and Surgeons, Baltimore, 1885 on the staff of the Mount Sinai Hospital aged 75, died suddenly, May 18, of coronary thrombosis

Sidney J Richardson, White Cloud, Mich., Chicago Homeopathic Medical College, 1903, member of the Michigan State Medical Society, aged 65, died, April 20, of pneumonia

Chester Chesterfield Groff, Richmond Hill, N Y., Baltimore Medical College, 1904, served during the World War, aged 53, was found dead, May 31, in a hotel at Baltimore

Judge Crayton Buckelew, Sulligent, Ala., Chattanooga (Tenn.) Medical College, 1898, member of the Medical Association of the State of Alabama, aged 63, died, April 27.

George E. Wiley, Bristol, Va. (licensed in Virginia, under the Exemption Law of 1885), member of the Medical Society of Virginia, city health officer, aged 83, died, March 25.

Joseph Godfrey ♂ Lancaster, Wis., Rush Medical College Chicago, 1880, past president of the Grant County Medical Society, aged 79, died, May 23, of coronary occlusion.

Lisle William Woodhouse, Torrington, Conn., Jefferson Medical College of Philadelphia, 1916, member of the Connecticut State Medical Society, aged 44, died, April 5.

Sidney Harris Easton ♂ Peoria Ill., Rush Medical College, Chicago, 1913, member of the Clinical Orthopedic Society, served during the World War, aged 44, died, May 8.

Leslie W. Keyes, St. Joseph, Mich., Columbus (Ohio) Medical College, 1882, aged 79, died, April 30, in Whitehall, of angina pectoris, myocarditis and arteriosclerosis.

William M. Popplewell, Vista Calif., Ensworth Medical College, St. Joseph, Mo., 1896, aged 72, died March 31 in the Oceanside (Calif.) Cottage Hospital, of carcinoma.

John Maxwell Pearson ♂ Glendale, Ariz., Georgetown University School of Medicine Washington, D. C., 1907, aged 50, died suddenly, May 12, of coronary occlusion.

John R. Abner, Hamlet, Ind., Curtis-Physio Medical Institute, Marion, 1884, on the staffs of the Holy Family and Fairview hospitals, La Porte, aged 77, died, May 24.

Grant Francis Tanner ♂ Turtle Lake Wis., Medical Department of Hamline University, Minneapolis, 1895, aged 68, died, April 22, of acute nephritis and myocarditis.

Henry Hessin Nichols, Hatch, N. M., Jefferson Medical College of Philadelphia, 1896, at one time coroner of Marshall County, Iowa, aged 66, died suddenly, April 5.

Christopher Morris Kelly, Grand Rapids Mich., Niagara University Medical Department, Buffalo, 1890, aged 71, died, April 16, in the Kent County Receiving Hospital.

William Pafford Bullard, Sopchoppy Fla., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1916, aged 42, died, April 22, in a hospital at Thomasville Ga.

Herbert A. Francisco, Rutland, Vt., Bellevue Hospital Medical College, New York, 1891, aged 67, was found dead in bed, June 1, of cardiovascular renal disease.

J. Edwin Caldwell, Perryville, Ky., University of Louisville Medical Department, 1888, member of the Kentucky State Medical Association, aged 73, died, May 9.

Wesley Grant Simmons ♂ Dover Plains, N. Y., Medico-Chirurgical College of Philadelphia, 1898, aged 65, died May 8, in the Presbyterian Hospital, New York.

Delos D. Stevens, Paralta Iowa, Western Reserve University Medical Department, Cleveland, 1882, aged 86, died, April 1, of myocarditis and mitral stenosis.

Isaac Newton Hutt, Ogden, Ark. (licensed in Arkansas in 1903), aged 61, died, March 20, in the Michael Meagher Hospital Texarkana, of acute appendicitis.

Louis Victor Leone, Hartford, Conn., Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1890, aged 74, died, May 6, of bacterial endocarditis.

John M. F. Barron, Milner, Ga. (licensed in Georgia in 1887), member of the Medical Association of Georgia, also a minister, aged 78, died, April 30.

Henry Clay Dorroh, Ashland Ky., University of Louisville School of Medicine, 1910, served during the World War, aged 65, died suddenly, April 18.

Fred Lawrence Schaffner, Ottawa, Ont., Canada, Trinity Medical College, Toronto, 1887, aged 79, died, May 22, of myocarditis and arteriosclerosis.

Josephine J. Resnik Krupp, New York, Woman's Medical College of Pennsylvania, Philadelphia, 1910, aged 45, died, May 15, of cerebral hemorrhage.

Pauline Wilson Bredow, Glenwood, Fla., University of Michigan Homeopathic Medical School, Ann Arbor, 1900, aged 59, died, May 8, of carcinoma.

Sheldon Pierce Hewins, Stockton, N. Y., Chicago Homeopathic Medical College, 1888, aged 74, died, March 18, of hemiplegia and arteriosclerosis.

John William Hopkins, Fayetteville, W. Va., Kentucky School of Medicine Louisville, 1894, aged 74, died, May 6, of a self inflicted bullet wound.

Karl Walter Allison ♂ Youngstown, Ohio, College of Physicians and Surgeons, Baltimore, 1911, aged 51, died May 22, of cerebral hemorrhage.

Thomas Henry Tracy, Los Angeles (licensed in Ontario in 1880 and Massachusetts in 1894), aged 77, died, March 16, of bronchitis and heart disease.

Henry Bernice Ford, Tompkins, Sask., Canada, Queen's University Faculty of Medicine, Kingston, Ont., 1885, died, March 31, of heart disease.

Robert Lee Grimes, Urbana, Ohio, College of Physicians and Surgeons, Baltimore, 1890, aged 70, died, April 17, of carcinoma of the prostate.

D. E. Hewitt, Carthage, Mo., Missouri Medical College, St. Louis, 1881, aged 77, died, April 19, in Aberdeen, Wash., of cerebral hemorrhage.

Charles Henry Franz, San Francisco, Jefferson Medical College of Philadelphia, 1888, served during the World War, aged 69, died, June 5.

Aime Trudel, Ottawa, Ont., Canada, M.B., Laval University Faculty of Medicine Quebec, Que., Canada, 1879 and M.D., in 1881, died April 19.

Louis Theophile Pare, Nicolet, Que., Canada, Laval University Faculty of Medicine, Quebec, 1883, aged 75, died, in April, in New York.

Edward Charles Dreher, Wilkes-Barre, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1893, aged 63, died, March 4.

Franklin William Boeck, Rochester, N. Y., University of Pennsylvania Department of Medicine, Philadelphia, 1899, aged 64, died, May 3.

Francis Marion Murray, Delaware, Ohio, Jefferson Medical College of Philadelphia, 1877, also a pharmacist, aged 80, died, April 25.

James Burnett Ford, Asbury Park, N. J., Howard University College of Medicine, Washington, D. C., 1918, aged 44, died, April 26.

Edwin Davis, Tulsa Okla., University of Arkansas School of Medicine, Little Rock, 1913, aged 56, died, March 27, in a local hospital.

Ellsworth Gamble, Waverly, N. Y., Eclectic Medical Institute, Cincinnati, 1889, aged 71, died, May 21, of cerebral hemorrhage.

Ira William Daly, New York, Long Island College Hospital Brooklyn, 1918, aged 42, died, May 12, in the Fitch Sanitarium.

William N. Haynes ♂ Victor W. Va., Kentucky School of Medicine Louisville, 1894, aged 64, died, May 10, in a hospital at Ranelle.

William R. Beck, Huntington, Ind., Kentucky School of Medicine Louisville, 1892, aged 70, died, May 21, of coronary thrombosis.

Eugene Clayton Mowry ♂ New York, University of Vermont College of Medicine, Burlington, 1889, aged 74, died, April 27.

George W. Post, Milton, Wis., Chicago Medical College, 1883, bank president, aged 75, died, May 10, of cerebral hemorrhage.

James E. Duncanson, Wray, Colo., Lincoln (Neb.) Medical College of Cotner University, 1898, aged 77, died, April 23.

Lorenzo Waldemar Bolan, Ridgewood, N. J., New York Homeopathic Medical College, 1885, aged 81, died, April 21.

William Joseph Halbeisen, Camden, N. J., Jefferson Medical College of Philadelphia, 1897, aged 64, died, May 1.

James D. Hamrick, Carrollton, Ga., University of Georgia Medical Department, Augusta, 1885, aged 77, died, May 7.

Harry George De Pew, Kansas City, Mo., Louisville (Ky.) Medical College, 1891, aged 70, was found dead in May.

Oscar Dunham, Creelsboro, Ky., University of Louisville Medical Department, 1897, aged 69, died, May 4, of carcinoma.

Gardner Wells Hall ♂ Boston, Johns Hopkins University School of Medicine, Baltimore, 1901, aged 59, died, April 21.

Horace Greeley Padget, Tully, N. Y., Syracuse University College of Medicine, 1908, aged 62, died, April 29.

William Daniel Potter, Clinton, Miss., Memphis (Tenn.) Hospital Medical College, 1892, aged 65, died, May 11.

J. C. Merle Drake, Erie, Pa., Hahnemann Medical College and Hospital, Chicago, 1880, aged 79, died, April 14.

Annie M. Hoppins, Los Angeles, Chicago Homeopathic Medical College, 1880, aged 95, died, April 28.

James Henry Duggan, Irwinton Ga., Southern Medical College, Atlanta, 1884, aged 70, died, May 11.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product (2) the name of the manufacturer, shipper or consigner (3) the composition, (4) the type of nostrum (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

No Septo—No-Septo Laboratories Tacoma Wash Composition Essentially a volatile oil such as turpentine in petrolatum For chronic sores soft corns piles boils dandruff scalp diseases etc Fraudulent therapeutic claims—[N J 21544 August 1934]

Mentholyptus—Crilego Pharmacal Co Los Angeles Composition Essentially volatile oils including those of camphor eucalyptus and menthol in a petrolatum base colored green For pneumonia bronchitis asthma rheumatism eczema etc Fraudulent therapeutic claims—[N J 21545 August 1934]

Bevill's Lotion—Bevill Co Birmingham Ala Composition Essentially salicylic acid carbolic acid alcohol and water perfumed with winter green For skin troubles piles etc Fraudulent therapeutic claims—[N J 21547 August, 1934]

Ercolin—Peoples Drug Stores, Inc Woshington D C Composition Gallic acid and glycerin dissolved in water For hay fever catarrh sinus trouble etc Fraudulent therapeutic claims—[N J 21548 August 1934]

Moroline—Red Line Products Co Brooklyn Composition Petrolatum For sores wounds sore throat coughs etc Fraudulent therapeutic claims—[N J 21551 August 1934]

Asma Tea—Asma Tea Co New York Composition Essentially ephedra licorice perilla seed and a nut For asthma bronchitis hay fever etc Fraudulent therapeutic claims—[N J 21553 August 1934]

Liberty Tonic—Clyde Collins Chemical Co Memphis Tenn Composition Essentially epsom salt ferric chloride extracts of plant drugs including a laxative with a small proportion of salicylic acid and water For blood, kidney and bladder disorders indigestion etc Fraudulent therapeutic claims—[N J 21556 August 1934]

Liberty Liniment—Clyde Collins Chemical Co Memphis Tenn Composition Essentially a petroleum distillate such as kerosene and a small amount of wintergreen Fraudulent therapeutic claims—[N J 21556 August 1934]

Gly Tone Tonic—Clyde Collins Chemical Co Memphis Tenn Composition Essentially epsom salt plant drug extracts small amounts of salicylic acid and an iron compound with water For blood kidney and stomach disorders etc Fraudulent therapeutic claims—[N J 21556 August 1934]

Liberty Nerve and Gland Treatment—Clyde Collins Chemical Co Memphis Tenn Composition Essentially baking soda (92 per cent) and starch Fraudulent therapeutic claims—[N J 21556 August 1934]

Endazola—Ray Sales Co and Endazon Co Inc New York Composition Essentially zinc oxide (12 per cent) salicylic acid (4 per cent) and volatile oil such as turpentine oil (5 per cent) incorporated in wool fat For eczema psoriasis chronic sores etc Fraudulent therapeutic claims—[N J 21557 August 1934]

Tee Tone Aspirin Tablets—Red Line Products Co Brooklyn Composition Aspirin 5 grains per tablet For relief of Rheumatism Lumbago Sore Throat Toothache Earache Influenza Sleeplessness Fraudulent therapeutic claims—[N J 21558 August 1934]

Texas Mineral Crystals—Dollar Crystal Co Omaha and Walgreen Co Chicago Composition Essentially crystallized Glauber's salt with small amounts of epsom and common salt For rheumatism stomach trouble skin diseases neuritis high blood pressure etc Fraudulent therapeutic claims—[N J 21559 August 1934]

Licoin Cough Mixture—MacAndrews & Forbes Co Camden N J Composition Essentially plant drug extracts including speac and licorice with ammonium chloride alcohol (73 per cent by volume) sugar and water Fraudulent therapeutic claims—[N J 21561 August 1934]

Baume Analgesique—American Pharmaceutical Co. Inc New York Composition Essentially menthol (23.4 per cent) and wintergreen (0.5 per cent), in an ointment base For rheumatism bronchitis bunions coughs croup earache etc Fraudulent therapeutic claims—[N J 21575 August 1934]

Velvetol—Bunny Drug Co and Biddle Purchasing Co New York Composition White petrolatum For wounds, sore throat etc Fraudulent therapeutic claims—[N J 21570 August 1934]

Vermiflax—Biddle Purchasing Co, New York Composition Essentially ground kamala and a small amount of starch in a mixture of alcohol and water For common worms tapeworms, etc Fraudulent therapeutic claims—[N J 21573 August 1934]

Geuda Springs Crystals—Geuda Crystals Co Geuda Springs, Kan Composition Essentially common salt (92.6 per cent) with small amounts of Glauber's and epsom salts and calcium sulphate and a trace of phosphate For constipation liver and kidney disorders rheumatism eczema obesity etc Fraudulent therapeutic claims—[N J 21569 August 1934]

Hunt's Solve—A B Richards Med Co, Sherman Texas and Allied Drug Products Co Chattanooga Tenn Composition Essentially chrysarolin carbolic acid sulphur volatile oils including sassafras and small amounts of a mercury compound and iodine in a base of petrolatum and rosin For all skin disorders Fraudulent therapeutic claims—[N J 21584 August 1934]

Premo Ergot Apiole Capsules—Blackman & Blackman New York Composition Essentially plant material including aloe volatile oils such as apiole and savin and traces of ergot alkaloids For female disorders Fraudulent therapeutic claims—[N J 21585 August 1934]

Alkalex Powder—Standard Chemical Co Des Moines Iowa Composition Essentially large amounts of calcium carbonate and baking soda with small amounts of magnesium carbonate and bismuth subcarbonate For stomach disorders including ulcers. Fraudulent therapeutic claims—[N J 21586 August 1934]

Nu Pine—Ray Sales Co New York Composition Essentially alcohol (80.8 per cent) volatile oils such as camphor and eucalyptol and water For hay fever sinus congestion, bronchial asthma etc Fraudulent therapeutic claims—[N J 21589 August 1934]

Minwater Crystals—Minwater Crystal Co Dallas Texas Composition Essentially dried Glauber's salt with small amounts of sodium carbonate and common salt For rheumatism diabetes stomach, bladder and kidney disorders etc Fraudulent therapeutic claims—[N J 21593 August 1934]

Seven A's Iron Tonic—Clyde Collins Chemical Co Inc Memphis Tenn Composition Essentially epsom salt iron chloride, a small amount of salicylic acid extracts of plant drugs and water For stomach kidney liver and blood disorders Fraudulent therapeutic claims—[N J 21594 August 1934]

Beatsol Drawing Salve—G & W Laboratories Inc, Jersey City N J Composition Essentially sulphonated bitumen incorporated in petrolatum For boils, carbuncles ulcers fells etc Fraudulent therapeutic claims—[N J 21595 August 1934]

A Vol Tablets—D P C Laboratories Holton Kan Composition 13 to 15 grains of acetphenetidin per tablet Misbranded because below professed standard or quality claimed, namely Two and one-half Grs acetphenetidin misbranded also because of fraudulent therapeutic claim tends to relieve pain—[N J 21596 August 1934]

Winsol Corlevo—Winsol, Inc Boston Composition Essentially plant drug extracts including alkaloids and valeric acid sugar alcohol and water For female disorders Fraudulent therapeutic claims—[N J 21598 August 1934]

Cascarets (Chocolate Flavor)—Sterling Products Co Inc Wheeling W Va Composition Lozenges essentially containing laxative drugs including phenolphthalein (21 grains per lozenge) incorporated in sweetened flavored chocolate Adulterated because strength and purity fell below professed standard and quality under which it was sold misbranded because of confusion with the old time Cascarets made from cascara sagrada whereas the active ingredient in the chocolate flavored Cascarets is phenolphthalein misbranded also because of fraudulent therapeutic claims as a remedy for habitual constipation etc—[N J 21777 September 1934]

Cascarets—Sterling Products Company Inc Wheeling W Va Composition Lozenges essentially containing phenolphthalein (0.62 grain each) plant drug extracts including cascara sagrada and licorice with flavoring oils including wintergreen and sassafras and sugar Misbranded because represented as being chiefly candy and having cascara sagrada as potent ingredient whereas cathartic action was due to phenolphthalein and the stuff was not candy misbranded also because fraudulently represented as a cure for habitual constipation—[N J 21793 September 1934]

Vitaliten—Vitaliten Co Los Angeles Composition A mixture of senna and maté For obesity, stomach and kidney disorders etc Fraudulent therapeutic claims—[N J 21778 September 1934]

Bron Co Capsules—Pacific Laboratories Inc, Los Angeles Composition Sodium and ammonium chlorides and sulphate a phenolic compound and acetanilid (0.042 gram per capsule) For all forms of bronchitis pulmonary catarrh cough etc. Fraudulent therapeutic claims—[N J 21780 September 1934]

Phenlin Oils—John H Wood Co Philadelphia Composition Ointment of petrolatum and paraffin with small amounts of cresylic acid and water Adulterated because strength and purity below professed standard and quality misbranded because fraudulently represented as a preventive against infection—[N J 21781 September 1934]

Tru Asplagum—Tru Lax Mfg Co Newark, N J Composition Essentially aspirin and salicylic acid in a mixture of sugar, starch and gum For sore throat rheumatism tonsillitis, influenza, etc Fraudulent therapeutic claims—[N J 21782 September 1934]

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF PNEUMONIA

To the Editor—Will you please enlighten me as to the best form of treatment of lobar pneumonia in adults by answering the following: 1 Is Felton's serum (Lilly) of any value even if the pneumococcus does not fall in any of the four types? If it has been given before this is determined will it do any harm to the patient? 2 Is a cardiac stimulant other than whisky indicated when the pulse is below 130 regular and of good quality? 3 When a cardiac stimulant other than whisky, is indicated which is most efficacious: caffeine sodiobenzoate or digitalin? 4 Is diathermy to the chest an accepted treatment in lobar pneumonia and if so is it of any advantage over such a counterirritant as mustard plasters? Please omit name and address.

M D Iowa

ANSWER.—Obviously the answer to this question depends largely on the personal opinions and individual experience of the authority consulted. Even a symposium seldom yields a unanimous expression.

1 This query, as worded, indicates a misunderstanding in the mind of the inquirer concerning the number of types of pneumococci. In the original classification of Avery and his co-workers (Avery, O T, Chickering, H T, Cole, Rufus and Dodge, A R. Acute Lobar Pneumonia Monograph VII Rockefeller Institute for Medical Research, October 1917) there were three specific types of pneumococci and a fourth group, which contained all other strains. At the present time, workers in this field recognize thirty-two types of pneumococci and a small group of unclassified, or \times , organisms which may prove to be a number of specific types. The additional types were segregated by Cooper (Cooper, Georgia, Edwards, Marguerite and Rosenstein, Carolyn. The Separation of Types Among the Pneumococci Hitherto Called Group IV and the Development of Therapeutic Antisera for These Types, *J Exper Med* 19 461 (March) 1929).

The preparation referred to is made by injecting into horses, pneumococci types I, II, III and type IV (Cooper). There is no attempt to produce in the horses, antiserum for the other twenty-seven types of pneumococci, though most of these were formerly in group IV (Avery). It is not possible to make serums valent for all types of pneumococci by injecting a single horse. Some of these types of pneumococci are very toxic, yielding high mortality. For some of them, effective antisera have been produced (Bullowa J G M. The Therapeutic Value of Pneumococcus Type VII [Cooper] Serum, *Proc Soc Exper Biol & Med* 29 343 [Dec] 1931, Therapeutic Pneumococcus Type VIII [Cooper] Serum *THE JOURNAL*, May 12, 1934, p 1560).

The manufacturers evidently consider seriously the unitage in the serum against type I and type II only as these are the only units mentioned on the package. The claim that the addition of heterophile antibody is of clinical advantage is as yet unsubstantiated.

In accordance with present knowledge, the action of antiserum in pneumococcal pneumonia is entirely type specific. The amount of antiserum required depends chiefly on the day of the disease serum treatment is commenced and the possible presence of bacteremia. Evaluation of specific serum in small or large series of pneumonia patients without an attempt to type the pneumococci responsible is an unscientific procedure. It is misleading to practitioners to cite mortality rates in such heterogeneous series. No intelligent clinician would expect to benefit, by antipneumococcus serum, pneumonias of other than pneumococcus origin.

In view of the fact that there may be delay or difficulty in determining the correct type of pneumococcus, some consider it good practice to give to adult patients with pneumonia antipneumococcus serum for pneumococcus types I and II before the type is determined as pneumonias due to these types are the most frequent. The administration of the serum, however, does not release the clinician from the obligation to determine the type of pneumococcus involved by at least several attempts to obtain the type from sputum or by blood cultures. He should give enough serum to have a therapeutic effect or to determine whether some other type is involved. The administration of pneumococcus antiserum of a type different from that causing the pneumonia does not harm a patient. It may produce serum

sickness and it may sensitize the patient to serums of animals from which it is made. These are annoying but are not adequate objections in view of the serious character of lobar pneumonia and the advantage of earlier administration of serum.

2 and 3 The frequency of the pulse should not be considered an indication for cardiac stimulation in pneumonia. A pulse rate of 120 is frequently considered an indication for oxygen therapy. The indications for cardiac stimulants are the same as in the absence of pneumonia, namely signs of congestive failure. When bacteremia and toxemia are overcome by the administration of specific antiserum in types for which it is available, the pulse rate will fall without stimulants. Fall in pulse rate is more important than fall in temperature as a guide to adequate serum dosage. When the pulse rate does not fall after adequate serum dosage there may be (1) a suppurative complication, (2) invasion with another organism or (3) serum sickness. In some large pneumonia services, whisky is not given as a routine to patients with pneumonia.

Cardiac stimulation with drugs such as digitalin and caffeine sodiobenzoate have little place in the newer management of the lobar pneumonias. Early termination of the illness with specific antiserum and relief of anoxemia with oxygen obviate the need for cardiac stimulation by terminating the disease. Patients with the lobar pneumonias usually require sedatives. Caffeine sodiobenzoate may in some patients increase irritability and prevent sleep.

Patients with the lobar pneumonias most frequently die of (a) A bacteremia for which there is no treatment other than specific antiserum. (b) Pulmonary edema, the mechanism of which in lobar pneumonia is as yet ill understood but for which 50 per cent dextrose with insulin may be helpful (Bullowa J G M. Pulmonary Edema Occurring in the Course of Lobar Pneumonia Treated with Intravenous, Hypertonic, Fifty per Cent Glucose Solution and Insulin. Report of a Case, *M Clin North America* 15 1115 [March] 1932). (c) Dehydration, for which large intravenous infusions of saline solution with dextrose may be beneficial. (d) Or, rarely, congestive failure, for which digitalis may be beneficial.

The present point of view concerning digitalis therapy is well expressed by John Wyckoff, Eugene F Du Bois and I Ogden Woodruff (The Therapeutic Value of Digitalis in Pneumonia, *THE JOURNAL*, Oct. 25, 1930, p 1243). They conclude, after a thoroughly controlled study involving 742 patients that "the routine giving of digitalis to patients with lobar pneumonia is dangerous."

Clinical symptoms of digitalis toxicity are not a sufficient guide in digitalis therapy in lobar pneumonia to prevent an increase in mortality when the drug is used.

When given in doses too small to show any effect, it causes no changes in mortality. They observed an increased mortality in all types of pneumococcal pneumonia except in patients suffering from pneumonias due to pneumococcus type II.

4 Diathermy to the chest is not an accepted specific treatment in lobar pneumonia. It may be used as an adjuvant for purposes of counterirritation, but it has no specific action and has no advantage over other less involved means such as the one mentioned by the inquirer. It has the disadvantage of complicating the administration of oxygen by introducing a fire hazard and requiring the discontinuance of oxygen administration while diathermy is being given.

Carl Binger has summarized his researches on this subject in chapter 15 of volume 1 of the "Principles and Practices of Physical Therapy" by Mock, Pemberton and Coulter (Hagerstown Md., W F Prior Co, Inc., 1934). He says "There is no evidence that the temperature of the pneumococcal lung can be raised to more than a degree above the systemic temperature."

There is no reason to believe that exudates will melt as the result of diathermy. Binger, in concluding his study, infers that the benefit alleged to be due to the use of diathermy may be caused by the 'mental attitude of the patient, which can be greatly influenced by the magic of a dancing blue spark and by the feeling that he is being regularly and energetically treated.' His experiments were performed at the Rockefeller Institute Hospital and involved actual measurement of the temperature in the lungs after treating patients suffering from lobar pneumonia with diathermy.

In spite of recent praise of diathermy in pneumonia, addressed to the public in a monthly lay journal, it is not an important primary or adjuvant therapeutic measure for the lobar pneumonias. The crux of the problem of the pneumonias is the presence or absence of bacteremia. Only such therapies as terminate bacteremia, neutralize toxemia or prevent the establishment of bacteremia can be said to be primary specific treatments.

PAINFUL SCAR AFTER EXCISION OF
BARTHOLIN CYST

To the Editor—What treatment would you advise for a painful scar following excision of a cyst of the Bartholin gland? At times especially at the premenstrual and postmenstrual periods the patient complains of swelling and marked tenderness over the scar. This cyst was completely excised nearly eighteen months ago and the region was examined by an experienced surgeon who thought there was no recurrence of the cyst. I have used 10 per cent sulphurated bitumen solution and fluidextract of thuja with some relief but no permanent effect. Please omit name.

M D Wisconsin

ANSWER—Painful scar is frequently due to the development of a neuroma in the scar tissue. Such neuromas may likewise produce tenderness even though the neuroma is microscopic. Verification of the occurrence of the intermittent swelling of which this patient complains is an important diagnostic point. Its existence would indicate that there is a gland remnant sufficient to produce the symptoms. A single examination would not rule this out. Obviously the condition should be studied at the time the patient complains of swelling. If the mass is found, however small it might be a reexcision would be justified in view of the long continued complaint. In the absence of local changes the diagnosis is most probably neuroma. Mild roentgen therapy from three to six treatments of one-third erythema dosage at intervals of five to seven days, may result in cure. Injection of 0.5 per cent procaine hydrochloride at the time of discomfort sufficient to produce mild distention of the labium and repeated daily or once every other day, may serve the purpose. Finally, even in the absence of actual swelling, excision of the old scar with its neuroma may be necessary to establish a cure.

PRIMARY MYOCARDIAL FAILURE AND VASCULAR
COLLAPSE

To the Editor—Dr Bernard Fantus in his article on fever regimen (*THE JOURNAL*, Aug 18 1934 p 484) cautions one to distinguish between primary myocardial failure and vascular collapse. The differential diagnosis here, as well as the therapy for the former would be appreciated. Please omit name.

M D Georgia

ANSWER—The term "primary (acute) myocardial failure" should be limited to those circulation insufficiency crises in which loss of cardiac efficiency plays the leading part. In infectious disease it is usually the "heart failure with normal rhythm." The heart failure of diphtheria is the classic example of such a condition. It is characterized, as far as differential diagnosis is concerned, by a relatively greater fall in systolic blood pressure than in diastolic pressure, and by diminution in the volume and a muffling of the first heart sound. The most reliable index to the severity of the condition is the degree of diminution of the pulse pressure. The therapy of this condition should include absolute rest in the prone position without pillows, the patient not being permitted to sit up for any purpose whatever. He should be kept warm and quiet. He must be fed, not allowed to feed himself. The diet should be liquid and given in very small quantities, brandy may be added in small doses. If there is a tendency to emesis, the stomach should be kept empty and salt solution given by rectum or dextrose solution (from 10 to 20 cc. of 25 per cent) slowly infused into the vein. Dextrose candy might be the first food admitted by mouth as soon as the extreme emergency has passed. Cardiovascular pressor substances are the drugs that may be employed with the best hope of benefit in this condition. Pituitary (pitressin, 1 cc intramuscularly every six hours) is probably the most valuable. Epinephrine is active but fleeting and ephedrine insufficient when the patient's condition is bad though it may be of value as a prophylactic, given every six hours (ephedrine sulphate 0.1 Gm). The degenerated heart muscle does not respond to digitalis, and strychnine or atropine is of no value when the heart itself is affected. If there is a tendency to emesis a stimulant such as aromatic spirit of ammonia (1 cc in a wineglassful of hot water) may be given as frequently as required to overcome sinking spells and whip up the circulation until other remedies have had time to be absorbed. Oxygen may be of value if there is any sign of cyanosis.

In vascular collapse, the common cause of circulation failure in acute infections, it is not the heart that has failed but the musculature of the peripheral blood vessels. It is for this reason that with the clinician, vasomotor drugs play such a great part in this condition. Strychnine in heroic doses (hypodermically up to 4 mg every two hours) is the drug of first choice. If there is a tendency to stupor caffeine sodiobenzoate (a 0.5 Gm ampule every four hours excepting at bedtime) is likely to be valuable, and, in the collapse of the crisis accom-

panied by a "leaky skin," atropine (1 mg hypodermically) may be of special value. The cardiovascular pressure substances (pituitary, epinephrine) are likely to be of value here, possibly because of their vascular action and possibly also as a method of restorative therapy, for a part of the vascular failure may be due to febrile degeneration of the endocrine glands. Dextrose saline phleboclysis (drop by drop infusion) is indicated because of the decreased blood volume, the low blood chloride level, and the tendency to acidosis. Up to 3 liters of 10 per cent dextrose in saline solution may be given daily, unless a tendency to edema asserts itself. If the blood vessels are "leaky" 6 per cent acacia solution in saline solution or blood transfusion in amounts not exceeding 500 cc, might be beneficial. If fluid in quantity can be given by mouth, infusions are contraindicated. Of course absolute rest in the head-low posture must also be enforced in this condition.

USE OF DEXTROSE IN CORONARY THROMBOSIS

To the Editor—Please evaluate the use of dextrose in the treatment of coronary thrombosis particularly as to time to begin the treatment, frequency of dosage and statistical information as to the results. I am prejudiced against its use because some patients are so apprehensive of intravenous medication. Please omit name.

M D New York

ANSWER—In coronary thrombosis, the nature of the pathologic process and its normal involution preclude the proper evaluation of the results of most forms of therapy or a reliable statistical study of therapeutic results. Marvin has advocated the use of dextrose intravenously from the fifth to the twenty-first day. He has used from 10 to 50 cc of the 50 per cent solution daily and has had gratifying results. Other clinicians begin its use earlier in some cases in smaller amounts or in larger amounts of a weaker concentration.

The objection to the use of intravenous therapy in an already apprehensive patient is a valid one, especially when what are probably equally good results may be obtained more easily.

When the blood supply to an area of heart muscle is diminished, it is hoped that by increasing the blood sugar concentration the deficiency of blood supply may be in part compensated for and it is for this reason that dextrose is recommended. Dextrose given intravenously, however, is rapidly carried from the blood and stored or excreted. It may also increase the blood volume temporarily and so add to the load on the heart. If it is wished to raise the sugar intake, it may be done by a high carbohydrate diet or by adding sugar to the diet or in various forms to beverages.

Hypertonic dextrose solution is also given to relieve the passive congestion that may be a consequence of the cardiac damage, and for this it is effective. Equally good or better results may be obtained by the use of some one of the newer and less toxic mercurial diuretics, especially those combined with small doses of theophylline. These can be given intramuscularly with little or no discomfort or even intravenously, with less disturbance.

TRAUMATIC ULCER OF DUODENUM

To the Editor—I have recently observed a man—a stevedore—who while loading heavy cylinders on a car by means of wooden skids was struck on the epigastrium by a broken end of a skid. He became weak, left his work and after forty-eight hours was seen by me. He had had that morning a tarry stool. Investigation showed hemorrhage into the bowel and later a duodenal ulcer. Is it the consensus that such trauma to the abdomen may cause hemorrhage in a preexisting duodenal ulcer? Please omit name.

M.D., Washington

ANSWER—Traumatic ulcer of the duodenum is a problem that has interested internists for a good many years. Many clinicians believe that there is no such thing as chronic traumatic ulcer. Perhaps the best recent article on the subject, together with a discussion of the literature, is by Crohn and Gerendasy (*THE JOURNAL*, May 27, 1933, p 1653). There is also a comprehensive review of the literature in the 1930 edition of Richard Stern's German textbook on the influence of trauma in producing visceral conditions. The medicolegal angle is particularly important because unwarranted claims can be made on this basis. A physician who was called as an expert witness to testify against an individual who claimed that his occupation, which was that of filing, produced a duodenal ulcer, recognized the name, when the papers were put in his hands, and was able to produce films of the man taken several years previous to his employment by the company in question, showing clearly that he had a duodenal ulcer at that time. This would be the only explanation for the ulcer phenomena that suddenly appear following an injury, because all experimental data show rapid healing of the normal mucosa when exposed to trauma. The criticism of nearly all cases of traumatic ulcer is to be found

in the fact that chronic peptic ulcer is notoriously latent at times. Most of the cases in the literature have no evidence particularly from a roentgenographic angle to show that previous ulceration did not exist. The correspondent should study the article by Crohn and Gerendasy and also the foreign references. Trauma can unquestionably excite hemorrhage in a previously existing chronic ulcer. This occurred in the case mentioned. In any event the literature mentioned is that most likely to yield the information.

ENDOCRINE DISTURBANCE

To the Editor—Will you kindly suggest diagnosis and treatment of a woman, aged 21, single, who is subject to severe muscular spasms of the limbs, neck and body just twelve to twenty-four hours prior to the menstrual flow? The menses began at 14, occurred every two weeks and lasted seven days. They continued in this manner until five years ago, when the flow continued for six weeks. A dilation and curettage was done whereupon an improvement was noticed for several months. The menses then became painful at onset and the patient began to have a sense of constriction about the throat, with sudden attacks of dyspnea even during sleep. These attacks increased in frequency and severity and were not associated with the menses. Thyroidectomy was followed by some improvement but all symptoms returned and became worse. The arm, leg, back and neck muscles being involved. During these attacks the body suddenly becomes rigid and the patient tosses about the bed attempting to get her breath. The attacks last from one to two hours unless relieved by a hypodermic of morphine sulphate or anesthesia with ether. The tonsils have been removed. The fundus of the uterus is anteverted but markedly retroverted. An attempt to correct the condition with a stem pessary gave no relief. The blood calcium is normal and Wassermann and Kahn tests are negative. Bromides and phenobarbital at times seem to decrease the severity of the attacks. The patient has shown no improvement in the past two years after having tried many doctors. Please omit name. MD Pennsylvania

ANSWER—This is probably a case of endocrine disturbance. Despite the lack of information concerning the condition of the ovaries and relative to the character of the menstruation during the last five years it would appear that genital disturbance is not the primary disorder, the chief lesion more likely concerns other endocrine glands.

In further search for the etiology of the patient's trouble the following may be considered: (1) roentgen examination of the sella turcica, (2) roentgen examination of the long bones and other search for parathyroid disturbance, (3) a basal metabolic rate determination, (4) search for a tuberculous focus, perhaps including roentgen examination of the lungs for the purpose of determining the likelihood of a lesion of the adrenal glands, and (5) an estimation of the hormones in the circulating blood (the estrogenic substance and the pituitary-like hormone), according to the technique of Robert Frank.

Despite the fact that the patient probably suffers from an organic lesion, the picture is atypical. A neurologic examination should be made to rule out with certainty the possibility of a purely functional disturbance.

LIPOMA AND TRAUMA

To the Editor—Will you kindly give me any references you may have regarding the formation of a lipoma following an injury? I would also appreciate your opinion as to whether an injury of tissues would predispose toward lipoma formation.

GEORGE P. EDDY, MD, Niagara Falls, N. Y.

ANSWER—The relation of trauma to lipoma is discussed by Leila C. Knox (Trauma and Tumors, *Arch. Path.* 7:274 [Feb.] 1929). The paragraphs in this article on lipoma are as follows: "Wurz (*Beitr. z. klin. Chir.* 26:567, 1900) carefully analyzed the histories of twenty-eight patients with lipoma and concluded that only one of the tumors could be suspected of being a traumatic one. The patient, a woman, had sustained a fall in which the left side of the pelvis was seriously contused and she had suffered continuous pain in the buttock for a few weeks, then, on examination, a large lipoma, apparently actively growing, was found embedded in the fat. This tumor might be placed in the group of fat necroses described by Lee and Adair (*Ann. Surg.* 72:188 [Aug.] 1920) and may have been only an instance of active regeneration and not of neoplastic growth or a preexisting tumor may have been rendered painful by the contusion. Siegfried Wolff believed four of his cases of lipoma to be traumatic. One of them followed a single injury. The others appeared on the shoulders following repeated contusions. Since this is so common a situation for lipoma, even in those whose occupations do not cause them to sustain injuries to the shoulders, its relationship to this trauma seems to be largely imaginary. Stern (Ueber traumatische Entstehung inneren Krankheiten, Jena, 1913, p. 487) studied this type of tumor and decided that it could not be in any way connected with an injury. Bosse and Lieschke (*Therap.*

Rundschau 3:433, 1909) believed that they had watched the origin of several cases of scrotal lipoma secondary to contusion, and Lieschke (Lipom und Trauma, dissertation, Berlin, 1911, quoted by Graef, *Centralbl. f. d. Grenzgeb. d. Med. u. Chir.* 17:603, 1913) collected sixty-two cases in which he believed that there was possibly a traumatic origin. These tumors also were described before the frequency and nature of traumatic fat necrosis and regeneration were well understood." The following statement by James Ewing (Neoplastic Diseases, ed. 3, 1928, p. 197) seems to answer well the question whether injury may predispose to lipoma: "Trauma of many types has seemed to act as an exciting factor with many solitary superficial lipomas in subjects in whom a local or general predisposition must be assumed to exist."

TREATMENT OF EARLY SYPHILIS

To the Editor—A girl, aged 16 years, married, came into my office with a general alopecia and one large ulcer located on the labia majora. She was anemic and weighed 90 pounds (41 kg.). I made a clinical diagnosis of tertiary syphilis. Serologic tests were made which confirmed the clinical diagnosis with four plus Wassermann and Kahn reactions. I gave her ten doses of neoarsphenamine intravenously ranging in dosage from 0.3 to 0.45 Gm. The first three doses were 0.3 Gm. each, the remainder 0.45 Gm. When she had taken the sixth dose her hands and feet became dry, rough, scaly and cracked. The condition was confined to the palmar and plantar surfaces, which would bleed from cracks. I carried the fact in mind that I might have an arsenical dermatitis developing but did not withhold the neoarsphenamine treatment but gave her four more doses which did not seem to aggravate the condition. At the same time she was taking the neoarsphenamine I gave her potassium iodide in 20 to 40 grains (1.3 to 2.6 Gm.) doses after meals and prescribed ordinary eczema treatment containing coal tar and avoided the use of water on her hands. The ulcer has gotten well and her hair is coming back thick but her hands are about as described. I have started sodium bismuth thioglycollate intramuscularly. The patient feels much better and has gained about 15 to 20 pounds (7 to 9 kg.) with the use of neoarsphenamine and she has had two doses of sodium bismuth thioglycollate. What do you think about the continued use of the heavy metal intramuscularly and what would you suggest as to the treatment of the hands and feet? I had intended to give fifteen or twenty doses of sodium bismuth thioglycollate. Please omit name. MD Kentucky

ANSWER—It would seem that a labial ulcer with associated alopecia in a girl of 16 is more suggestive of a chancre than a tertiary lesion of syphilis. The amount of treatment given has been adequate thus far, but, as the inquirer recommends, a bismuth compound should be added to the therapeutic program at this time. The dermatitis on the hands might be an arsenical dermatitis of the so-called fixed eruption or a keratoderma palmaris et plantaris, the possibility of a fungous infection or a keratoderma blennorrhagica as a result of gonorrhea seems quite unlikely. Likewise, in view of the amount of treatment the patient has had it would be quite improbable that syphilis is the cause of the eruption on the hands and feet.

Now that it has been decided to give the patient a bismuth compound, it would be well to avoid arsphenamine for the time being. If the eruption tends to fade out during this interim, it would tend to support the diagnosis of arsenical eruption. On the other hand, if no material change is noted during the bismuth treatment the likelihood of a keratoderma must be considered. For this, hot water soaks for a half an hour each day, followed by the application of increasing strengths of salicylic acid ointment, would seem warranted, starting with a 3 to 5 per cent salicylic acid ointment and increasing according to the patient's tolerance.

LOW BLOOD SUGAR

To the Editor—I should like to know of instances of extremely low blood sugars. What is the lowest that has been reported?

BEN HICKS METCALF, MD, Ruskin, Fla.

ANSWER—Complete absence of detectable sugar in the blood has been reported by Wagner and Parnas (*Ztschr. f. d. ges. exper. Med.* 25:361, 1921).

Seale Harris (*Endocrinology* 16:29 [Jan.-Feb.] 1932) has reviewed all the cases of spontaneous hypoglycemia that have appeared in the American and Canadian literature up to June 1931. Some more recent reports are as follows:

Rabinovitch, Jacob and Barden, F. W. *Am. J. M. Sc.* 184:494 (Oct.) 1932.

Bowen, B. D., and Beck, G. M. *Ann. Int. Med.* 6:1412 (May) 1933.

Judd, E. S., Kepler, E. J., and Ryncarson, E. H. *Am. J. Surg.* 24:345 (May) 1934.

Moore, Henry, O'Farrell, W. R., and Headon, M. F. *Brit. M. J.* 1:225 (Feb. 10) 1934.

Zeckwer, Isolde, T. Hypoglycemia in Diabetes Associated with Obstruction of the Pancreatic Duct. *Arch. Int. Med.* 64:330 (Sept.) 1934.

AUTOINTOXICATION

To the Editor—The subjects of systemic infection from the colon and the absorption of fecal toxins from the colon are of great interest and dissatisfaction to me. Papers in which therapy of a wide range of disease states is discussed often include the statement that the bowels should be regulated or 'constipation combated'. Often the recommendation is made that the colon be 'cleaned out' by the use of purges or enemas. I assume that the mere fact of existence of the human race today should in itself offset the theory that fecal toxins are absorbed by the colon thus providing the soil for the development of disease states degenerative chronic or acute. I assume further that biologic selective action has resulted in producing a human race that is more or less immune to or resistant to the process of absorbing bacteria and their toxins from the colonic wall. I wish to know the mechanism whereby catharsis is thought to be of value in the therapy of infectious disease states when the specific causative organism is known and which has no connection with the colon near or remote bacteriologically or anatomically. If absorption of toxins actually occurs from the contents of the colon is there any evidence whatever that a colon cleaned out by catharsis or enemas is any the less potent as a source of systemic toxemia? Actually is there any such disease state or entity as intestinal toxemia or auto-intoxication? If so how are these states diagnosed? The conclusion is becoming rather fixed in my mind as the result of my own experiences that catharsis and enemas do not appreciably change the picture of the typical routine course of most systemic disturbances of whatever nature. It appears further to me that constipation is often the result of deficient water intake and that catharsis aggravates the deficiency. The proponents of the auto-intoxication theory have often impressed me by the vehemence of their assertions but I should like to know of some carefully controlled unprejudiced research work to back up their dogmatic theories. Please omit name. M D

ANSWER—There is no well defined disease entity of 'intestinal toxemia' or auto-intoxication. Even the concept of 'biliousness,' so definitely and eloquently described by our forefathers in medicine has been abandoned. There is no carefully controlled unprejudiced research to substantiate the auto-intoxication theory. So far as we know constipation is prone to produce mechanical and reflex disturbances rather than chemical injury. Patients with infectious diseases usually get along quite as well, if not better without the customary 'cleanout'. There is no evidence that either cathartics or enemas make the colon contents less toxic.

CAUSE OF POSTOPERATIVE SHOCK

To the Editor—R. A. a man aged 23 came to my office with a history of abdominal pain in the right lower quadrant of four days duration. Examination revealed typical symptoms of a perforated appendix. The temperature was 101 F the leukocytes numbered 26,000 and polymorphonuclears were 83 per cent. Operation showed a ruptured appendix not localized, with free pus in the pelvis. The post-operative course for five days was apparently uneventful. Distention and vomiting appeared gradually with an increase in temperature to 102. This was treated for a day by a continuous gastric tube and lavage hypodermoclysis of dextrose and saline solution as well as with ampoles of pitressin. This appeared to be of some help. Most of the distention disappeared and the patient had a good bowel movement. In two days the distention began again to appear and the same procedure that had been used intermittently for the past two days was used continuously that day. The patient appeared to be in good condition and had small bowel movements mostly liquid and distention appeared to be only moderate when a stomach tube and pitressin with adjuvant treatment was used. However it was thought best not to delay and an ileostomy was performed liberating a great deal of liquid and some gas. It was found that plastic adhesions of fibrin had formed about the intestine near the appendix causing a partial obstruction. This was not treated at the time. Operation was done quickly with the least possible trauma and disturbance of the bowel. The patient was returned to the ward apparently in good condition but a few hours later appeared to go into deep shock. The temperature gradually rose until twelve hours after operation it was 108. The pulse rate was 160 and respiration 32. The patient died at this time. The usual stimulants—pitressin epinephrine intravenous dextrose and saline solution—did not have the slightest effect. I have seen and had several similar cases. What is the cause of the profound cardiovascular collapse which apparently does not respond at all to any stimulation. What is the cause of the excessive stimulation of the heat center? Would slow emptying of the intestine prevent the profound shock? What operative or other treatment would you suggest in the treatment of this type of case beyond possible earlier performance of an ileostomy? Kindly omit name and address.

M D New York

ANSWER—As stated the condition described is observed not infrequently. No generally accepted explanation has ever been offered. It is likely that the cause of death is not the same in all instances. The anesthetic that was used during the performance of the ileostomy is not stated. There is evidence that a person who is profoundly sick withstands spinal anesthesia very poorly. Circulatory collapse is apt to follow the giving of the usual amount of the anesthetic into the spinal canal. The use of large quantities of drugs that produce vasoconstriction such as epinephrine may in itself produce acute circulatory failure. It is not likely that slow emptying

of the intestine would have prevented the profound shock. As suggested the earlier performance of an ileostomy might have been of help. The employment of repeated small transfusions of blood in place of the using of vasoconstrictor drugs and of intravenous salt solution might have been of benefit.

In summary no entirely adequate explanation for the condition described is available at the present time.

USE OF HEARING DEVICES

To the Editor—I would appreciate information as to the latest instrument to aid nerve deafness the price if possible and where I can obtain it. If there is more than one new model let me know about it. Mention only the ones that have proved a success.

L A COLEMAN M D Salisbury N C

ANSWER—Electrical hearing devices are often of considerable aid in cases of middle ear or conduction apparatus impairment but are of slight and sometimes no benefit when marked impairment of the auditory nerve or perception apparatus is present. It is difficult to say which is the latest instrument but there are several excellent ones on the market. Among them are the Audiphone, manufactured by the Western Electric Company, the Sonotone, produced by the Sonotone Corporation, the Acousticon, made by the Acousticon Corporation and the Fortphone, distributed in this country by Mager and Guggelmann. Some of them, especially when supplied with a bone conduction attachment are expensive. In many instances one type of instrument will give better results than another, so that the individual should test a number of these instruments of various makes in order to decide in his case which gives the greater amplification and is best suited for his own particular ears. One cannot say that any one instrument has proved a greater success than another, because of the personal element just mentioned.

CHRONIC ANKYLOSIS AFTER ARTHRITIS

To the Editor—A man aged 36 has ankylosis of the right knee from chronic gonorrheal arthritis. At present he is wearing a walking caliper. What do you consider the most effective of the following: bacteriophage, gonococcus vaccine (stock vaccine), milk products or intravenous products? The acute gonorrheal urethritis occurred about twenty years ago. He has had ankylosis for three years. Please omit name.

M D, Ohio

ANSWER—If the patient has had ankylosis of the right knee for three years there seems to be no indication for the products mentioned. The only curative measure now is arthroplasty which is a highly technical operation and must be done by a surgeon skilled in that type of operating.

In regard to the various products mentioned, one might parenthetically state that it is not so much the product used as the knowledge and experience in the use of each one that spells success or failure.

LACERATION OF SPLENIC ARTERY

To the Editor—Please send me information on the present authentic method of treating a lacerated splenic artery. What is the recognized method in surgery today? Please omit name.

M D New York

ANSWER—A torn or lacerated splenic artery will usually result in extensive intra-abdominal hemorrhage. An emergency operation with ligation of the splenic artery and vein with splenectomy is the procedure of choice, otherwise, even if bleeding has stopped, a delayed hemorrhage may occur.

When hemorrhage is excessive and the patient will not stand the shock of splenectomy, a large gauze pack may be introduced to control the bleeding and gradually removed after a few days. This does not so satisfactorily control the hemorrhage, and infection may result through the wound.

MANGANESE IN DIET

To the Editor—Is the element manganese now generally considered to be essential in the human diet? If so what is its function and is the daily requirement known? Has there been any work published on the subject since that of McCollum? Kindly omit name if this is printed in THE JOURNAL.

M D Wisconsin

ANSWER—There is no evidence at hand which would indicate that the element manganese is essential in the human diet. The work from the laboratory of McCollum at Johns Hopkins University and from Hart's laboratory at the University of Wisconsin would indicate that the absence of manganese in the diet of the rat leads to loss of fertility. There is no evidence, however that the average human diet is lacking in the element manganese.

Book Notices

New and Nonofficial Remedies 1935 Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1 1935. Cloth Price \$1.50 Pp 510 Chicago American Medical Association 1935

In this book the Council on Pharmacy and Chemistry lists and describes the medicinal preparations that it has found acceptable for general use by the medical profession. A glance at the list of the Council members and the long list of consultants appearing in the first part of the book gives ample warrant for the authority of the Council's selections.

Not only does the Council "accept" new preparations but from time to time it omits those which have been accepted but which have not with the lapse of time upheld their original promise of therapeutic merit. The list of omissions for 1934 shows that the Council has been mainly concerned in this respect with B acidophilus preparations and with antiseptics. Several preparations of each class have been omitted. The list of admissions does not reveal the presence of any preparation that promises to be epoch making in the sense that insulin was, for instance. However, the following newly accepted preparations are noteworthy, Carbarson, an arsenical used chiefly in the treatment of amebiasis (the Council published a special report on this drug, supplementing the preliminary report of 1932), Hippuran and Diodrast, two different types of urographic contrast mediums. Carotene, the precursor of vitamin A, Dilaudid, a substitute for morphine. Neo-Synephrin Hydrochloride, which has a number of advantages as a vaso-constrictor over synephrin tartrate, and Diothane, which represents a type of local anesthetic entirely different chemically from any heretofore accepted for N N R.

The description of products containing vitamins A and/or D have been revised to give the potencies in terms of the recently adopted pharmacopeial units, thus bringing some measure of uniformity into this heretofore chaotic field. No doubt the book will be revised next year to conform with the new Pharmacopeia in its entirety.

A valuable feature of the book is the grouping of preparations in classes. Each of these is introduced by a general discussion of the group. Thus the silver preparations, the iodine preparations, the arsenic preparations, the animal organ preparations and the biologic products are each preceded by a general discussion of the particular group. These general articles compare the value of the products included in the group with similar pharmacopeial and other established drugs which it is proposed that these proprietary preparations shall supplement or supplant.

Physicians who wish to know why a given proprietary is not described in New and Nonofficial Remedies will find the "Bibliographical Index to Proprietary and Unofficial Articles not Included in N N R" of much value. In this section (in the back of the book) are given references to published articles dealing with preparations that have not been accepted. These include references to the Reports of the Council, to Reports of the A M A Chemical Laboratory and to articles that have appeared in THE JOURNAL.

Psychology and Health. By H. Banister. M.Sc. Ph.D. Director of Psychological Studies in St. John's College, Cambridge. Cloth. Price \$2.50. Pp. 256. New York: The Macmillan Company. Cambridge, England: The University Press. 1935.

It has been a problem to find a book dealing with all of psychotherapy which could be used in classes or groups for social workers and nonspecializing physicians, but after reading the present volume the problem would seem to be at least temporarily solved. While the author is not a medical man, his grasp of the subject from all standpoints is unusually effective, particularly in view of the fact that his work is being done in England, where child guidance and mental hygiene are not stressed to the same degree to which they are in this country. One of the features that have invalidated so many of the books dealing with psychotherapy in the past has been the fact that short chapters usually fail to give a comprehensive and accurate point of view of each subject treated. For instance, the usual book on abnormal psychology might devote a chapter to the Freudian psychology but when the reader has finished with it he has only the idea that Freud has a point of view which is linked up with sex, which point of view has little to do with his own problems in life. Banister, however, has devoted chapters to the Freudian and Adlerian concepts as well as to those of Janet and Jung, which are so simply written yet so full of valuable material that they might easily be read by the layman to his benefit and not to his bewilderment. In addition, the present volume is the first one that deals in a simple manner with the problems specifically facing the medical man. Of course, each of the subjects to which a chapter has been devoted can be studied more completely in the literature, and to some, such as invalidism, mental deficiency, suggestion, hypnosis, conversion hysteria, anxiety states, compulsions and obsessions, whole monographs have been devoted. While the chapter on the problem child and that dealing with infantile sexuality concern themselves with these subjects only from the point of view of a few small cases rather than with a general attempt to cover the whole field, the presentation should nevertheless reveal to the physician who is not actively engaged in psychiatry the fact that some technical approaches to these fields exist. The book concludes with several chapters on psychologic treatment and, since three chapters in the middle of the book deal with the relationship of mental hygiene to physical ailments, it might be well for the physician who is interested in the mental sphere of medicine, even though he is not a psychiatrist, to know that this book is in existence.

The Hermannsdorfer Sauerbruch Diet. By Robert Wollheim and Walter H. Schaumsland. Ph.D. With a foreword by Joseph Alexander. M.D. Paper. Price \$1. Pp. 64. New York: Professional Scientific Service. 1935.

Considerable emphasis has been placed on the diet in the treatment of tuberculosis since the days of Hippocrates. During the centuries, numerous advocates of various diets have appeared only to disappear without leaving anything of value in the treatment of tuberculosis. There is no question that diet is essential in the treatment of any chronic disease. However, it must be kept under the control of the dietitians and the

physicians and out of the hands of the faddists. When properly used in conjunction with other forms of treatment, such as Wollheim and Schaumsland prescribe, it is capable of producing beneficial results in properly selected cases. The Gerson salt-free diet in the treatment of tuberculosis was introduced in 1923. Two years later, Sauerbruch and Hermannsdorfer employed this diet but concluded that some changes were necessary, and this volume is a discussion of their modification. The diet has been found of most value in cases of tuberculosis of the skin. However, they also believe it to be of considerable value in tuberculosis of the bones and joints, genito-urinary tract, and lymph nodes. They also observe considerable improvement in some cases of pulmonary tuberculosis. Considerable space is given to the mechanism of the diet, and attention is called to the fact that it is not definitely understood because its underlying principles involve the whole field of body chemistry. One chapter, entitled "Notes for Physicians," calls attention to the importance of the general supervision of the treatment, characteristics of the diet, food element intake, fluid intake, medication and accessory therapies. In this chapter it is obvious that the authors do not depend on the diet alone in the treatment of tuberculosis. In other chapters such subjects as application of the diet, dietary rules, prohibited foods and notes for dietitians are discussed. The appendix which outlines the daily food schedule and calls attention to the differences between the Hermannsdorfer-Sauerbruch and the Gerson diets, is very useful. Some space is given to recipes and to menus.

Personal Hygiene Applied. By Jesse Feiring Williams. A.B. M.D. Professor of Physical Education, Teachers College, Columbia University. Fifth edition. Cloth. Price \$2.25. Pp. 528 with 145 illustrations. Philadelphia & London: W. B. Saunders Company. 1934.

This book in its four earlier editions has deservedly been one of the most popular in the field of college hygiene. Interest is stimulated at the outset by a philosophical discussion of health and is sustained throughout the book by well chosen and exceptionally readable subject matter. In this as in most books there are some points to which exception might be taken. For example, there is what seems to be an undue emphasis on exercise as a health measure, and an unjustified prominence given to outdoor air and vaccines in the treatment of tuberculosis. Then, too, some of the statements concerning communicable diseases need revision. These are based on American Public Health Association standards of 1917, when the statement that there is no immunization against scarlet fever was correct. Such minor inaccuracies, however, become inconspicuous in comparison to the soundness of the general ideas and the great mass of specific information presented. The claims of thorough revision are apparently based on the omission of the sections on Christian science, chiropractic and osteopathy, the bringing down to date of several statistical tables, the revision of a few paragraphs, and the addition of a little new material. Possibly 2 or 3 per cent of the total subject matter is revised. This relatively little change from the previous edition, however, is no reflection on the quality of the book, which should continue to be useful for the instruction of college students on the subject of personal hygiene.

Clinical Laboratory Methods and Diagnosis. A Textbook on Laboratory Procedures with Their Interpretation. By R. B. H. Gradwohl. M.D. Director of the Gradowohl Laboratories, St. Louis. Cloth. Price \$8.50. Pp. 1028 with 352 illustrations. St. Louis: C. V. Mosby Company. 1935.

This book heralds the return of the larger and more comprehensive textbooks on clinical laboratory methods. For some time most of the current books on the subject have been concise treatises devoted particularly to interpretation of laboratory procedures. In this book the standard technique of accepted procedures is given in the strictest detail together with an interpretation of all data obtained by standard tests. The usual subjects of clinical laboratory methods are covered comprehensively. The chapters on hematology, bacteriology, parasitology and exotic pathology are, however, noteworthy in volume and completeness. An unusual chapter for a book of this type is a concise but adequate discussion of postmortem examinations. The text has been carefully edited and the illustrations are used to good advantage. The colored illustrations are particularly well done and greatly enhance the value of the descriptive

material. The technic of the various laboratory procedures is clearly described in a step by step manner so that even the novice will have no difficulty in carrying them out. The reader will find this book an unusually rich source of information on clinical laboratory procedures. Many valuable points and modifications of standard procedures are given that greatly facilitate otherwise laborious methods. The author is well qualified both by actual experience and by long years of teaching this subject to anticipate and supply useful data that are seldom found under one cover. As with most first editions, certain chapters have received undue emphasis, but this does not impair the general value of the book. The clinician and laboratory worker will find the book of the greatest value. It is questionable whether the general organization and manner of presentation lend themselves suitably in a textbook for the medical student on laboratory diagnosis as the courses are ordinarily arranged in the medical curriculum. Nevertheless the book is an unusually complete work on clinical laboratory methods and their interpretation and is a fertile source of information.

Les migraines. Etude pathogénique clinique et thérapeutique. Par Pasteur Valléry Radot, professeur agrégé à la Faculté de médecine de Paris et Jean Hamburger, interne des hôpitaux. Avec la collaboration de P. Blamoutier. Paper. Price 45 francs. Pp 231 with 4 illustrations. Paris: Masson & Co 1935.

This book closely resembles in its appearance and system of handling the various divisions of the subject in the monograph on urticaria written by Pasteur Valléry-Radot and Lucien Rouques in 1930. After a brief historical introduction there is an excellent description of the various forms of migraine including ophthalmic, simple, associated and certain unusual forms. This is followed by a long chapter on the pathogenesis in which various theories, such as spasms of cerebral blood vessels and sympathetic irritation are discussed. The next chapter deals with studies of the blood and biologic researches both during and between attacks. The fifth chapter treats the etiologic factors. After discussing heredity and endocrinology in relation to migraine, the authors spend considerable time on biliary migraine, which, they believe is an extremely common form of migraine and for which they prescribe quite enthusiastically repeated duodenal drainage after the fashion of Lyon. The authors are lukewarm toward the American idea that allergic or, as they call it, "anaphylactic" migraine is an important group. In their experience true allergic migraine is rare and they discuss at length the poor results obtained by the American investigators in connection with skin tests. They believe that the good results obtained in some cases by dietary manipulation is due, for the most part, to a lessening of biliary and hepatic infections, although they admit that there are some cases of true allergic hypersensitivity to one or more foods. There is a rather extensive chapter on the relationship between migraine and epilepsy. The chapter on the treatment of migraine is surprisingly small and adds nothing to our knowledge, except for its emphasis on repeated duodenal lavage. The book is well written, the description of attacks is exceptional, the headings are clear and the discussions are easily understandable. The tone of the book is quite conservative and the authors take great exception to some of the more radical reports, especially those emanating from certain American investigators.

Diabetes Mellitus and Obesity. By Garfield G. Duncan, M.D., C.M. Associate in Medicine in the Jefferson Medical College, Philadelphia. With an introduction by Thomas McCrae, M.D., Professor of Medicine in the Jefferson Medical College. Cloth. Price \$2.75. Pp 215 with 9 illustrations. Philadelphia: Lea & Febiger 1935.

This small volume contains an excellent summary of the practical essentials necessary for the proper handling of the diabetic and the obese patient. The author adheres to the Allen and Joslin dietary formulas, but his discussion is sufficiently broad to make the book useful to those desiring to use any other dietary regimen. The work is to be commended for its concern with the individual variability of the patient and its completeness as regards the inclusion of the various vicissitudes that require some modification of routine therapy. Many illustrative examples and tables of food values, are included. The desire for brevity has admittedly rendered the theoretical discussion somewhat dogmatic. Because of the fact also that this discussion is rather conservative in tone, one can hardly recom-

mend the volume as a good source of present day theory. However, the theory given is adequate for its intended purpose, namely, as a background for the practical considerations. And any shortcomings in this respect are far outweighed by the evident experience and common sense which the author brings to bear on his subject.

Fracastor Syphilis or the French Disease. A Poem in Latin Hexameters. By Girolamo Fracastoro. With a translation notes and appendix. By Heneage Wynne Finch, M.A. and an introduction by James Johnston. Abraham CBE DSO M.A. Cloth. Price 10/6. Pp 263 with 10 illustrations. London: William Heinemann Ltd. 1935.

This gives first a brief and interesting account of the history of syphilis and a particularly attractive sketch of the life of Fracastor. Fracastor is one of those men whose name by a trick of history has been immortalized through its association with a great fact. Fracastor suggested the name syphilis which physicians took up with eagerness for a disease that they could not before better describe than by laying the disease on their neighbors. The name syphilis which was first used in his famous poem, has held ever since. But in a way this was not altogether fortunate for Fracastor, because it has led the world to overlook that he was one of the foremost men of his time. In a period of great men he was not only one of the most penetrating students of syphilis but was centuries ahead of his time in his insight into the origin of contagions and had a greater claim to fame in that he first clearly suggested the microbic origin of contagious diseases. Before Galileo he tried using compound lenses for making a telescope for viewing the heavens. And he was a Latin poet of such distinction that he had the praise of Bacon, Pope and Hallam. As Wynne-Finch says of his verse, 'It is not too much to say that he was an almost perfect writer of the hexameter, proving, as Virgil had done before him how delightful and varied a melody it was capable of in the hands of a master'. In short Fracastor is worth knowing, and there is no place where knowledge of him can be gotten more easily than in this work.

But the main value of the book lies in the translation of "The Syphilis". The translator has wisely avoided the temptation to put it in verse, but he has put it into beautiful poetic prose. He has attained the rare achievement of giving the spirit as well as the substance of the poem. Take the following chosen almost at random: 'Urania, thou knowest the causes of things, thou knowest the stars and the manifold motions of the heavens and the shores of the sky, Grant me thy presence, and sport with me in the peaceful shade, whilst soft breezes whisper and the myrtle woods answer my song and Benacus resounds from his hollow caverns. Tell me, Goddess, what causes after so many ages brought forth for us this unaccustomed disease? Was it borne by the Western Sea, and so came to our world at the time when a chosen band set sail from the shores of Spain, and dared to attack the foam and the unknown waters of the wandering ocean and search out lands lying in a new world?'

The present translation is a delight.

A Diabetic Guide Written Primarily for the Doctor's Patient and with Suggestions to the Doctor for Assisting Him. By Samuel Evans Massengill, M.D. Third edition. Cloth. Price \$2. Pp 214 with illustrations. Bristol Tenn.: S. E. Massengill Company 1934.

The problem of successfully treating diabetes primarily involves teaching the patient to care for himself. The help of the physician is indispensable at times of emergencies, if and when these arise, but the patient must learn the day to day management if he is to do as well as he ought to do. The numerous manuals, primers and guides that have appeared in recent years bear witness to the general acceptance of this principle. Dr. Massengill in preparing his guide has followed the general plan of earlier books of this nature, covering the material in a manner that is readily intelligible to the layman. Food tables and recipes are included. A chapter is taken up with brief notes on various complications of diabetes, and such subjects as marriage, sleep, tobacco and vacations. The author adheres to the diet plan advocated by those who believe in moderate restriction of carbohydrate and the supplying of enough fat to provide the calories required by the individual. Alcohol is found useful sometimes to increase appetite and has a place in rendering more comfortable the disturbances of chronic disease and old age. The procedure advocated is sound, the book is well written and it can safely be recommended.

Corrective Rhinoplastic Surgery By Joseph Nathan M.D. Attending Plastic Surgeon Sydenham Hospital New York City Cloth Price \$9 Pp. 218 with 242 illustrations by Joseph Tamarin M.D. New York Paul B. Hoeber Inc. 1935

In his introduction the author defines the scope of his book as embracing "types of nasal deformity commonly met with in times of peace, with congenital enlargement of the entire nose or any of its component parts, and with congenital or traumatic deficiencies and displacements." He has succeeded in presenting the subject in a clear and graphic manner. The technique of most of the procedures follows that described by Joseph who is given full credit. Certain innovations and modifications suggested by the author are timely and helpful. The text is sufficiently detailed on all phases of the subject matter with the possible exception of the chapter on nasal fractures which might have been given a little more extensive discussion in view of its importance. The chapter on saddle nose, on the other hand is particularly thorough and leaves nothing to be desired. The author is eminently fair in his estimate of the type of operation best suited to the different varieties of saddle nose and reflects the best opinions of the day. The illustrations and drawings bring out certain details of technique that are more or less obscure in most books on this subject. While it is true that one cannot become a plastic surgeon merely by the reading of books it is also true that the surgeon with a knowledge of fundamentals and only a limited experience can be enormously assisted in carrying out heretofore unfamiliar procedures. This excellent work merits the enthusiastic reception not only of those who are doing this type of work exclusively but of rhinologic surgeons in general.

Growth and Development of the Young Child By Winifred Rand A.B. R.N. Specialist in Parental Education at the Merrill Palmer School Detroit Mary E. Sweeney M.S. M.A. Nutritionist at the Merrill Palmer School Detroit and E. Lee Vincent Ph.D. Psychologist at the Merrill Palmer School Detroit Second edition Cloth Price \$2.75 Pp. 429 with 57 illustrations Philadelphia & London W. B. Saunders Company 1934

Many of the difficulties in the growth and development of children are directly traceable to maladjustments in family life. It is also true that antepartum care has a profound influence on postnatal growth and development. Nevertheless, such knowledge as is available at the present time concerning these matters is not as widely applied as it should be. Knowledge alone is of no value unless that knowledge is actually used in the antepartum care of the mother and in the guidance of the child during the first years of life, when his character is being formed. It is to supply this need for a simple but scientific presentation of antepartum care and the postnatal care of the child that this book was written. In the present edition have been included newly learned facts concerning the endocrine glands, new observations on growth during infancy and childhood, and the important advances made in feeding and nutrition. A chapter has been included on biologic development. Questions and exercises have been appended to each chapter to aid in the use of this book for teaching purposes. Teachers, students of child care, and parents all will find this book full of valuable material.

A Survey of Industrial Mental Hygiene Compiled under the auspices of the School of Medicine University of Pittsburgh by C. H. Henninger M.D. T. M. T. McKennan M.D. and Samuel C. Gomory M.D. Paper Pp. 140 Pittsburgh 1934

This is a volume consisting of numerous tabulations in which the relationship of mental disorders and physical disorders to industry is brought out. There are two points of view one treating of the psychiatric diagnosis in relation to the types of occupation and the second, a number of chapters reversing the process and showing the kinds of body injuries and mental symptoms that are related to physical defects, industrial accidents, compensation cases and industrial poisons. There is a part of a chapter dealing with mental symptoms in industrial poisoning. The chapters on mental deficiency in industry and neuroses and psychoses, consist largely of paragraphs defining the conditions and showing in one sentence the limitations of workers who are suffering from these diseases. A number of interesting points can be culled by an earnest perusal, but as a rule the material is too specific to be inspiring. For one who

is interested in industrial medicine, the volume should be of great interest, but, since nothing new in the way of treatment or analysis of industrial cases along mental hygiene lines has been developed this work would seem to serve the general practitioner and psychiatrists to only a limited extent.

A Synopsis of Surgical Anatomy By Alexander Lee McGregor M.Ch., F.R.C.S. Lecturer on Surgical Anatomy University of the Witwatersrand With a foreword by Sir Harold J. Stiles K.B.E. F.R.C.S. Second edition Cloth Price \$6 Pp. 644 with 839 illustrations Baltimore William Wood & Company 1934

Those who are not familiar with this textbook will find it one of the most originally conceived and written works of its kind. The author originally intended it as a compilation of anatomic facts of practical value for the senior student and practitioner. He made no pretense at completeness but endeavored to present in outline essay form discussions complete in themselves on important anatomic subjects. It is well illustrated with original and comprehensive diagrams. The plan is to present briefly the surgical anatomy of the normal and the abnormal. The book exemplifies the painstaking effort of a surgeon who desires to develop a concise and instructive epitome of surgical anatomy. It is highly recommended to the student and the practitioner who desire to relate the principal anatomic facts to their practical application in surgery.

Curso práctico de fisiología Por los Doctores Alejandro Lipschütz profesor de fisiología de la Universidad de Concepción Chile y Jaime Pl. Suñer Bajo del Instituto de fisiología de Barcelona Tomo I Biología y fisiología general Tomo II Movimientos secretiones y psicofisiología Paper Price 25 pesetas each Pp. 235 with 63 illustrations 245 with 149 illustrations Madrid Javier Morata 1934 1935

This extensive laboratory manual provides directions for a combined practical course in physiologic chemistry and physiology. Most of the conventional material in both branches is described in an understandable way, and a great deal of explanatory material not immediately related to practical exercises is included. There is a commendable emphasis on the physicochemical aspects of biochemistry. A good deal of attention is paid to experiments on the glands of internal secretion including exact descriptions of experiments on the gonads, in which field one of the authors has done a good deal of original investigation. The work as a whole suffers greatly from the absence of references to the original literature, although a great many names of investigators are mentioned. The large number of illustrations greatly enhances the value of the work to students and the inclusion of a considerable amount of discussion and collateral information makes the work an auxiliary textbook as well as a laboratory manual. It can serve as a useful basis for the fundamental training of medical students in the Latin American countries.

The Autonomic Diseases or the Rheumatic Syndrome By T. M. Rivers M.D. Cloth Price \$3 Pp. 299 Philadelphia Dorrance & Company Inc. 1934

In the study of the etiology of such diseases as arthritis the common cold, asthma and hay fever there is often a need for stretching one's imagination over a long range between cause and effect. Many times these distances are vague and too often blank. It is difficult to appreciate the relation between cause and effect. The author has therefore attempted to group the diseases that result from action of the causative agents through the autonomic nervous system. Since diseases of this class are productive of the greatest economic loss and suffering, any stimulating thought should be welcomed. The book, however, must be read critically and theory must always be dissociated from fact.

General Ophthalmology A Short Treatise for Students and Practitioners By S. A. Agatston M.D. F.A.C.S. Assistant Clinical Professor of Ophthalmology at the New York University Bellevue Hospital Medical School. Cloth Price \$2 Pp. 176 New York The Author 1935

This pocket size volume is a quiz compend type of outline covering the field of ophthalmology. It has no illustrations. Of necessity such a work cannot give a comprehensive discussion on any phase of the subject and can only serve as a guide for review in preparation for such examinations as are given by state boards or to applicants for internships. In our opinion, it is too brief and condensed to serve as a textbook for the teaching of ophthalmology.

Medicolegal

Malpractice Physician's Liability Not Removed by Award Under Workmen's Compensation Act—The plaintiff was injured in the course of his employment. He himself employed and paid the defendant, a physician, to treat him. The injured workman, the insurance carrier, and the industrial commission effected a settlement of the workman's claim under the workmen's compensation act. The physician-defendant was not a party to the settlement, nor, since he had been employed and paid by the workman, was he in privity with the employer, on whose behalf the insurance carrier acted. Nevertheless, when his former patient instituted suit against him he pleaded that in the settlement the plaintiff, his patient, received compensation for all his injuries, including the injury alleged to have resulted from the defendant's treatment. In the district court, Wells County, the plaintiff's suit was dismissed, and he then appealed to the Supreme Court of Colorado.

The question is, said the Supreme Court, whether the settlement under the workmen's compensation act may be invoked by the physician defendant in absolution of the charge of malpractice against him. The purpose of the appeal was solely to determine the law governing the case. If that should be decided in favor of the plaintiff, the physician-defendant could then be called on to answer to the charge of malpractice.

The liability of a tortfeasor—such as a physician guilty of malpractice—is predicated on fault, the liability of an employer under the workmen's compensation act is predicated on relationship. What the plaintiff received from or through his employer under the workmen's compensation act was paid because of that relationship. What he seeks to recover from the physician-defendant is based on the latter's alleged fault. To the workmen's compensation act the physician defendant was a stranger, an outsider does not share the burdens of that act which are imposed on an employer, nor is he entitled to its benefits. The Supreme Court quoted from *Ruth v Witherspoon-Englar Co*, 98 Kan 179, 157 P 403, with approval, as follows:

Even if circumstances had been shown sufficient to charge the defendant with responsibility for the fault of the physicians, the rule would not be altered for liability under the compensation act cannot be made to depend upon the degree of care exercised. A part of the loss occasioned by an accidental injury to a workman is cast upon the employer, not as reparation for wrongdoing but on the theory that it should be treated as a part of the ordinary expense of operation. So much of an employee's incapacity as is the direct result of unskillful medical treatment does not arise 'out of and in the course of his employment within the meaning of that phrase as used in the statute. For that part of his injury his remedy is against the persons answerable therefor under the general law of negligence, whether or not his employer be of the number.

To deny a remedy to the victim of malpractice simply because he has received compensation under the statute would be fraught with potential ill being. By the common law a physician or surgeon is beholden for injury to his patient resulting from malpractice. The court found no evidence to show that the legislature had abrogated the common law remedy and held that 'to allow orthodox determination is only just to plaintiff and is not unfair to the defendant.' The order of the district court, sustaining a demurrer in favor of the defendant, was reversed—*Froid v Knowles (Colo)*, 36 P (2d) 156.

Marriage Annulment for Impotence—The petitioner sued for the annulment of her marriage on the ground that her husband was at the time of marriage physically and incurably impotent. From a decree in her favor, her husband appealed to the Court of Errors and Appeals of New Jersey. The parties were married on Aug 28, 1932, and separated Nov 2 1932. A proceeding for annulment was begun Nov 10, 1932. It was conceded that the husband was from a sexual standpoint competent, except for prematurity of emissions. That prematurity, he contended, was not due to any defect on his part but 'to nervous resistance and assertions of pain by the petitioner.' The petitioner, said the Court of Errors and Appeals falls short in her essential proofs. There was no proof of impotence other than the fact that the marriage had not been consummated, and the petitioner's recital of the reason for its nonconsummation stood alone, uncorroborated. The peti-

tioner's proofs were deficient, too, in that they did not show that the impotence, if it existed at all, was incurable, and incurability is an essential characteristic of such impotence. It affords a legal ground for a decree of nullity. The petitioner made the charge, and the burden was on her to prove it. No proofs were offered of incurability of impotence, if impotence existed at all, and no proofs from which incurability could be presumed.

On a showing, however, of continued cohabitation, the wife, meanwhile remaining a virgin, the husband will be presumed to be impotent and the burden will be on him to overcome the presumption by proof that he is not at fault. How long a time must elapse before that presumption will begin to operate, the court had never decided and did not feel warranted in deciding in the present case. It was, however, clearly of the opinion that 'having regard for the vicissitudes of life, a period of two months is wholly inadequate to cause the presumption to arise.' As the petitioner did not prove her case the decree of nullity entered in her favor by the court of chancery was reversed—*Heller v Heller (N J)*, 174 A 573.

Medical Schools Classification by Licensing Board Lawful—Under authority of Public Laws of New Jersey 1924, c 184, the state board of medical examiners adopted a resolution setting out the requirements to be met by a class. A medical college in seeking to obtain a license to operate as such a college. To review the proceedings of the board fixing a standard for such colleges, the College of Mecca of Chiropractic obtained a writ of certiorari from the supreme court of New Jersey. When the proceedings were dismissed by that court, the college appealed to the Court of Errors and Appeals of New Jersey. The college contended that the action of the board in fixing requirements for the licensing of colleges should be set aside because the statute under which the board acted was unconstitutional. It contended that there was no power in the state to compel any privately conducted school to meet any requirement, unless the school was conducted in a manner inimical to the public health, public safety or public morals. That the act constituted an unlawful delegation of legislative authority to the board, that the act was unlawful special or class legislation, and that the act violated article [amendment] 14, section 1, of the Constitution of the United States, forbidding any state to deprive any person of life, liberty or property without due process of law or to deny to any person within its jurisdiction the equal protection of the laws. The Court of Errors and Appeals, however, affirmed the judgment of dismissal entered by the supreme court, adopting the opinion of that court 'that the requirements of the statute were just and reasonable regulations, that the legislature was within its rights in passing the act and that the act 'does not offend against any constitutional provision'—*College of Mecca of Chiropractic v State Board of Medical Examiners of New Jersey (N J)*, 174 A 562.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Common Type of Bundle-Branch Block.—Wolferth and Margolies made graphic studies of comparable time relations of certain events associated with the heart beat in the common type of bundle-branch block and various control cases. They found that a systolic bifid apex impulse can be recorded in some, but not in all, cases of bundle-branch block. It may also occur in cases without bundle branch block. Comparison of the interval between the beginning of the QRS complex and the beginning of the carotid pulse wave in cases with bundle-branch block, in normal controls and in cases of cardiac decompensation, indicates that ejection from the left ventricle is significantly delayed in the common type of bundle-branch block. The delay is associated with the particular type of aberrant spread of the excitatory process that occurs in the common type of bundle-branch block. Comparison of the intervals between the beginning of the QRS complex and the beginning of the C wave recorded from the veins immediately above the right clavicle in cases of the common type of bundle-branch block and normal controls shows no significant delay in bundle branch block. This suggests that in the common type of bundle-branch block there is no significant delay in the contraction of the right ventricle. In roentgen kymographic tracings of the aorta and pulmonary artery in the common type of bundle-branch block the interval between the beginning of the QRS complex and the beginning of the aortic pulse was prolonged in each case. In the normal controls with single first sounds, the differences in time between the beginning of the aortic and the pulmonary artery pulses fell within the limits of error of the method. In the cases with split first sounds, both with and without intraventricular conduction defects, the differences in time between the beginning of the aortic and the pulmonary artery pulses tended to be greater than in the control cases with single first sounds. The observations support the hypothesis that in the common type of bundle-branch block there is asynchronism in the beginning of ejection from the two ventricles owing to delay on the left side. The evidence also indicates that in some possibly all, cases with split first

sounds but without intraventricular conduction defect there is asynchronism in the beginning of ejection from the two ventricles. The association between asynchronism indicates that the split first sound has a right ventricular and a left ventricular component and that separation of these components is due to asynchronism in certain of the early phases of cardiac contraction in the two ventricles. Splitting of the second heart sound can be heard on auscultation and recorded in most cases of bundle-branch block. Splitting of the second heart sounds is due to asynchronism in closure of the two semilunar valves. In the common type of bundle-branch block, pulmonic closure usually precedes aortic closure. In cases with split second sounds but without intraventricular conduction defect, either aortic or pulmonic closure may come first. The evidence obtained is in accord with the hypothesis that the common type of bundle-branch block is due to delay in spread of the impulse on the left side. The view held by Eppinger and Rothberger and by Lewis is no longer tenable. No support was obtained for the statement that it is unjustifiable to attempt to localize the side of bundle-branch block from the direction of the major initial complex in the three limb leads of the electrocardiogram.

Course of Rheumatic Heart Disease in Adults.—DeGraff and Lingg describe the course of rheumatic heart disease, based on 644 patients who are dead, of a total of 1,633 patients who came under observation during ten years. Of these patients, 55.8 per cent were males and 44.2 per cent were females. Rheumatic heart disease usually existed alone (94.5 per cent) and was seldom combined with other etiologic types (5.5 per cent). The disease is one of childhood and early adult life, for it occurs and runs its course chiefly within the first four decades. After the age of 40 there is a small proportion of sufferers. Three fourths of those who survived to adult life are dead. The average age at initial infection is 17 years, at the first symptoms of cardiac insufficiency 28 years, at the first appearance of heart failure 30 years, and at death 33 years. That is, the average patient is infected at the age of 17 but will be free from symptoms and able to carry on ordinary physical activity for eleven years. He will then begin to suffer from diminished cardiac reserve, culminating in heart failure two years later. From this time to death, three years later, he is wholly an invalid or at least, in most cases, seriously incapacitated. The period of economic usefulness of a person afflicted with rheumatic heart disease is not more than eleven years after initial rheumatic infection, on the average, and in most cases less than nine years. Once symptoms of cardiac insufficiency appear, heart failure and death follow rapidly. Half of the patients suffer their first symptoms and failure and die within a period of from sixteen to twenty years, or between 20 and 40 years of age. To see even terminal stages of this disease after the age of 50 years is not a common experience. Death usually occurs as a result of a failing heart, but life is shortened in a fair proportion of cases by such conditions as subacute bacterial endocarditis, pneumonia and other diseases.

Reestablishment of Cardiac Circulation During Progressive Coronary Occlusion.—Robertson put the matter of cardiac nutrition during coronary obstruction to actual test in the living animal by producing gradual coronary occlusion and noting in what manner myocardial circulation was reestablished. There were two plausible routes by which these hearts could have been nourished, by the vascularized pericardial adhesions or by the vessels of Vieussens or Thebesius. He found that little or no nutritive function developed in those channels known as the vessels of Vieussens or Thebesius, which penetrate the myocardium from the heart cavities. Myocardial nutrition distinctly depended on the vessels contained in the pericardial adhesions. The microscopic studies, indicating little disturbance in the nutrition of the endocardial part of the myocardium, do not justify the conclusion that this part of the heart was fed by thebesian-like vessels. Intercoronary branches might have carried out this function. There was no evidence of an anastomosis developing between the epicardial or intercoronary vessels and the thoracic vessels by way of the aortic vasa vasorum to nourish these hearts.

Predisposing Factor for Normal Onset of Labor—Reynolds

points out that under the influence of estrogenic material the contractions of the uterus become increasingly coordinated and powerful in the latter part of gestation. Until this time the hormone influence of the substance is held in abeyance by virtue of the antagonistic action of the luteal hormone, progesterone, and possibly other hormones as well. As the ovum grows, uterine contractions become increasingly efficient, owing to the coordinating action of estrogenic substance and the marked degree of uterine distention. Later the uterine contractions become effective in expulsive force due in part at least to the shape of the full term uterus. The onset of labor may be determined by the time during gestation when the coordinated foregoing expulsive forces exceed the total restraining hormone and mechanical intra-uterine factors that make for the continuance of pregnancy. This statement should be regarded as a working hypothesis at best, in which the generalities are only approximate possibilities. The importance of the restraining influence of uterine emptying is suggested by the failure of Witherspoon to initiate labor by the administration of theelin near term.

Barbiturates in Primiparous Labors—In their study of 25 primiparas, Tritsch and Brown compared several barbiturates which were used in combination with other analgesic and amnesia-producing drugs. The drugs were diallylbarbituric acid, sodium iso amylethyl barbiturate and morphine sodium iso amylethyl barbiturate and rectal ether, sodium allylpropyl barbiturate with a mixture of opium and alkaloids and sodium allylisopropyl barbiturate with scopolamine. No adverse effect of serious or permanent nature was observed on any patient. None of the mothers died and none developed any complications traceable to the use of an analgesic. The authors conclude that barbiturates used alone are apparently of less value for the relief of pain during labor and for the production of amnesia in labor than they are when combined with other drugs. Barbiturates combined with sedative or amnesia-producing drugs appear to accentuate and prolong their action.

The labors were shortest in the patients in whom the greatest degree of analgesia and amnesia were observed. Ether by rectum used in conjunction with the barbiturates appears to delay labor to a degree. Barbiturates are excitants in about 25 per cent of all cases, and this condition is aggravated by the use of another excitant, such as scopolamine, and lessened by sedatives, such as a mixture of opium and alkaloids, and morphine. Apnea in the infants is more common when barbiturates are used during labor and is aggravated when a mixture of opium and alkaloids is used in addition. Considering safety of the mother and the infant, efficiency in producing analgesia and amnesia and simplicity of administration, the authors feel that the combination of sodium allylisopropyl barbiturate with scopolamine produced the most satisfactory results. Excitation produced by this combination is a deterring factor and requires special nursing care.

Inability to Duplicate Results of Sex Determination Test—In an attempt to duplicate the observations of Dorn and Sugarman, Pankratz studied four pregnant patients. The earliest specimen of morning urine used was that from a patient during the nineteenth week, and the latest during the thirty-ninth week of pregnancy. At various intervals injections of from 8 to 10 cc of pregnancy urine were made into the ear veins of selected young male rabbits and the testicles were excised and examined forty-eight hours later. Even when the animals were carefully selected as to age and descent of the testicles, there was considerable difference in the testicles of the controls. Spermatogenesis begins at a variable age, which cannot be accurately determined without histologic examination of the testicles. Difficulties were constantly encountered with experimental testicles in which spermatogenesis was not marked, and in some preparations there was a definite degeneration of some of the seminiferous tubules characterized by a large lumen and many pyknotic nuclei in the germinal epithelium. In a number of experiments a second injection of 10 cc. of pregnancy urine was made twenty-four hours after the first one. This did not affect the results as was found by later determinations. It was also noted that there was no correlation between enlargement of the testicles and active spermatogenesis. The observations agree in general with those of Daily, Curphey and Romer, and Murphy and De Reny. The author has been unable to duplicate the results obtained by Dorn and Sugarman with their sex determination test.

Use of Dinitrophenol in Schizophrenia—Looney and Hoskins studied the metabolic and therapeutic effects of 2,4 dinitrophenol and 3,5 dinitro-orthocresol administered consecutively to ten schizophrenic patients. Both drugs caused an increase in the rate of oxygen consumption with various other metabolic effects indicative of increased oxidative efficiency. The orthocresol proved to be the more potent but showed the propensity of causing discoloration of the skin and sclera. The ther-

putic results were indeterminate. Aside from the discoloration of the integument by the orthocresol neither drug, within the limits of dosage used, caused any perceptible harmful effects.

Blood Cerebrospinal Fluid Barrier in Mental Disorders—Rothschild and Hainberg investigated the distribution of calcium between blood and cerebrospinal fluid in 400 cases of mental disorder. In the schizophrenic group, 29 per cent of the calcium ratios were above 2.2 and 3 per cent were below 1.8. In neurosyphilis, 8 per cent of the calcium ratios were above 2.2 and 12.5 per cent were below 1.8. Low ratios occurred with greatest frequency in untreated dementia paralytica patients. The other groups showed a smaller proportion of abnormal results without any striking preponderance of increased or decreased values. The results were suggestive of a tendency toward decreased permeability of the blood cerebrospinal fluid barrier in schizophrenia and increased permeability in untreated dementia paralytica patients. There was a general correlation between the distribution ratios of calcium and bromide in schizophrenia, affective psychoses and untreated neurosyphilis. In the individual cases this correlation was frequently lacking. Low calcium ratios tended to occur in cases presenting increased amounts of protein in the cerebrospinal fluid and high ratios in cases showing decreased amounts of protein but this relationship was not consistent. The variations in the distribution ratio of calcium could not be accounted for by alterations in the protein content of the cerebrospinal fluid.

Ocular Reactions Due to Arsphenamine—In the experience of Skirball and Thurmon the occurrence of pathologic changes in the optic nerve head, the vitreous body and the retina in patients with syphilis during arsphenamine therapy are so

clear cut and definite that they form an easily recognized and an extremely important clinical entity. There can be no doubt that these untoward manifestations are due to the toxic effect of the arsenical compounds. The changes are observed in both early and late syphilis. Recovery is usually complete if the condition is diagnosed early and proper management is instituted. The authors discuss the clinical progress of twenty patients with syphilis who have been carefully studied in the departments of ophthalmology and syphilis, in whom neuroretinitis and vitreous changes occurred during the course of arsphenamine therapy. Careful observation has shown that changes occurred definitely after the administration of arsphenamine and that recovery occurred after its discontinuance. Exacerbations recurred with the resumption of arsphenamine, and recovery again with its discontinuance. This observation in a series of cases carefully checked indicates that there is a definite toxic effect on the nerve structures of the eye caused by the administration of arsphenamine compounds. Since it is imperative for the treatment of early syphilis to be continuous, further treatment during this complication may be carried on with iodides and with preparations of bismuth or mercury without affecting the return of the ocular condition to normal.

Psychosis Associated with Administration of Tryparsamide—Hoverson reviews the work of the last two years at the Kankakee State Hospital with tryparsamide, in which time a total of more than 2,000 injections was given to more than 200 patients. He believes that the occurrence of visual complications has been overemphasized, while other more commonly occurring changes have been neglected. In contrast to the four patients who showed visual changes during the tryparsamide medication, six patients presented the symptoms of a toxic psychosis. It seems that certain toxic features detectable by abnormal mental reactions are just as common a danger of contraindication to the use of the drug as are the commonly described visual changes. The nature of the toxic reactions and the facility with which they are recognized make the condition rather easy to detect and to treat successfully. Even though these reactions can occur, they should not serve to discourage any one from prescribing tryparsamide when it seems to be indicated. The psychosis, or mental reactions, in such cases is abrupt in onset, and the mental reactions of the individual in question undergo a decided change in the space of a few hours or days. The reactions observed are those of delirium and usually vivid hallucinations of either the auditory or visual type, or even both, attendant on these hallucinations are definite fear reactions with restlessness and overactivity. On the removal of the offending agent there usually results an abatement of the symptoms, with eventual recovery. Not all toxic reactions resemble this picture, but most of the symptoms enumerated are usually present in some degree.

Juvenile Paretic Neurosyphilis Studies—Prodromal symptoms occur in juvenile dementia paralytica, but Menninger considers these the initial symptoms of the disease. Dulness was the most frequent initial mental symptom, and convulsions were the most frequent initial neurologic symptom. The type of onset of juvenile dementia paralytica varies with the native mental endowment of the individual. There are three distinct groups: (1) those with a marked feeble-minded state in which the onset is vague and it often is impossible to set a date or age as the time of onset, (2) the moderately feeble-minded children, who make an insidious but definite failure of previously learned accomplishments, and (3) the group of children who have a period of normal development prior to the onset of the disease. The nature of the onset in the great majority of cases is insidious and very gradual, so that an average of three years elapses between the time of onset and of examination. Occasionally the onset is sudden, with a convulsion, the development of paralysis or acute excitement. The clinical course of the disease is remarkably uniform, with the development of certain characteristic physical, neurologic and mental changes. Remissions are rare in juvenile dementia paralytica. While a small proportion of patients improve, and apparently in very rare instances spontaneously, there is no convincing record of a permanent remission. Cases with a basic feeble-minded state may become negative serologically but rarely improve otherwise. Rarely is clinical improvement spectacular as seen so commonly

in the acquired form of dementia paralytica, and often the improvement is only transient. The outcome of the disease is nearly always death, which occurs occasionally in convulsions and with a relatively short period of acute physical ill health, or more often in a long drawn out failure, with the formation of contractures and a terminal intercurrent respiratory infection. The average duration of the disease is from four to five years, as compared to an average duration of two years of adult dementia paralytica. Several cases of a duration of fifteen years or more are cited. In general, the cases with early onset have a longer duration than cases with late onset.

Mnière's Symptom Complex—Furstenberg and his associates assume from their experiments that the symptoms of Menière's disease are due to the retention of sodium by the body. Apparently, the local tissues involved in Menière's disease have either an increased avidity for sodium or an unusual sensitivity to it. The therapeutic indications are to permit as small an intake of sodium as is possible and to prevent the accumulation of sodium by the body. The former is easily attained by means of diet and the latter by the administration of acid-producing salts, such as ammonium chloride. When these two factors have been controlled, the intake of water does not need to be considered. The authors have successfully treated fourteen cases of typical Menière's disease by this method. Each patient was carefully selected in an effort to rule out any obvious lesion, and every precaution was taken to eliminate psychic elements from the study. Each patient was hospitalized for a period of thirty days or more, and careful clinical and laboratory studies were made. Identical results were obtained for all patients. In no instance did the authors fail to produce an attack by the administration of sodium and not once were they disappointed in obtaining complete relief by their medical therapy. They are aware that presumptuous claims for medical therapy cannot be based on their meager statistics. Their desire is to suggest a new etiologic factor in the production of Menière's disease and to express the hope that it may lead to further research in therapeutics. Their treatment consists of a diet low in salt content, unrestricted or forced protein and calories as indicated. As medication, 3 Gm. of ammonium chloride in capsules is given with each meal, three days on and two days off. The ammonium chloride can be given in this dosage indefinitely. They have had patients with nephritis receiving ammonium chloride in this manner for a period of five years. The intake of water should be unrestricted although excessive quantities of liquids should not be taken. An approximately neutral low sodium diet should be given including certain foods which the author mentions.

Auditory Fatigue—Josephson reports the paradoxical results obtained in a series of experiments undertaken to study fatigue of hearing, with especial reference to the part played by the auditory end organ. The results indicate that prolonged stimulation with submaximal intensities, designed to fatigue, result, on the contrary, in an increased acuity of hearing manifested by a lower threshold. It is shown that this paradoxical phenomenon is not obtained in ears in which the auditory accommodative mechanism of the middle ear is defective, and that to this mechanism there is to be attributed, in part, the increased acuity of hearing acquired by the trained ear. Fatigue manifested by a rise of threshold of intensity is described as the earliest sign of progressive deafness. A theory of the mechanism of hearing is advanced, which predicates the conversion of the mechanical energy of sound into electrical energy by the cochlea, and the stimulation of the end organs of the organ of Corti by the electrical audiofrequencies thus produced. The "cochlear spread currents" are thus interpreted as the direct stimulus giving rise to the action currents of the auditory nerve. An exception to the manifestation of auditory fatigue in cases diagnosed progressive deafness was found in a group of cases that presented varied neurologic signs. The most consistent of these was the head-neck past-pointing sign. These cases showed no rise in threshold following prolonged stimulation, indicating that the deafness was of central nervous type. These tests offer a differential sign between peripheral and central nerve deafness. With their aid the author has been enabled to isolate a type of case which on encephalography shows deformation of the ventricles but no definitely localizable lesion, which responds to spinal puncture and injection of air with a marked improvement in hearing, some cases with a restoration of hearing to almost normal, and a clearing up of tinnitus, with disappearance of the head-neck past-pointing sign and other neurologic signs.

The Pyknolepsies—Jelliffe and Notkin consider the relationship of pyknoleptic attacks to narcolepsy, hysteria, spasmophilia and epilepsy, especially to petit mal attacks. In their tabulation of 190 cases they have eliminated eighty-four as frankly epileptic. The only apparent reasons that they were reported under the heading pyknolepsy were the frequency and the relative shortness of the seizures. In pyknolepsies one is dealing with the old problem of general epilepsy. Most of the reasons offered by the various workers for creating a separate entity can hardly stand criticism. The disappearance of the attacks at the time of puberty cannot be considered a sufficient reason for classifying them as a separate entity. There are numerous cases of cryptogenetic epilepsy in which the attacks disappear at puberty, and there are at the same time numerous cases of pyknolepsy in which the attacks persist during adolescence and later. The matter of deterioration has been entirely overemphasized, as if the absence of deterioration in epilepsy were an exception to the rule. Strohmayer has pointed out that only 30 per cent of the patients with epilepsy show evidence of mental deterioration. Not all the patients with pyknolepsy

whose cases have been reported in the literature retained their mental integrity. The lack of therapeutic response to medicinal treatment has been held up by many investigators as a criterion for the consideration of pyknolepsy as an entity which has no relationship to epilepsy. In pyknolepsy, as in epilepsy in general, some of the patients respond to one and others to another form of therapy, while a number of patients remain refractory to any sort of therapy, as, for instance, do epileptic patients with petit mal attacks. Sometimes a psychologic approach may be helpful in certain cases. As to the etiology one is probably dealing with the same situation as in cryptogenetic epilepsy and the attacks are probably closely related to petit mal seizures. In some of the reported cases and in one of the authors' cases there was a definite history of an injury to the head. In other cases there was evidence of a previous inflammatory process in the central nervous system, and in a third group affective instability could be considered a responsible factor in the lowering of the threshold of convulsibility. There is, however, in addition, some factor that is responsible for the unusual frequency of the pyknoleptic attacks, perhaps some metabolic process may be responsible for the phenomenon. In all probability, as in epilepsy in general there is a multiplicity of etiologic factors. The authors therefore suggest the existence of various types of pyknolepsy, which, together with the narcolepsies affect epilepsies and other well known paroxysmal disorders and make up the vast group of convulsive states.

Observations Following Left Temporal Lobectomy.—Fox and German resected the left temporal lobe of a right-handed man 3 cm. posterior to the junction of the rolandic and sylvian fissures for removal of an astroblastoma. Speech, vision, personality and restitution of function have been studied for fifteen months after operation. Analysis of the speech involvement revealed a deficient auditory receptive mechanism and impaired retention of auditory speech memories. In contrast to this, the visual mechanism suffered a relatively slight defect. It is concluded that the auditory component of speech is related to the dominant temporal lobe. The visual fields showed an upper quadrantic homonymous defect with the preservation of macular vision. An extensive macular representation in the optic radiation, similar to that found in the external gemulate body and calcarine area, is suggested. The principal personality changes were euphoria, some degree of emotional instability and slight reduction in drive. Functional recovery demonstrated two distinct phases: early, rapid improvement, probably related to edema and vascular changes produced by the operation and later a slowly progressive phase, apparently associated with reeducation, representing true restitution. The latter type of recovery indicates the establishment of new domains of integration.

Dacryadenitis in Hyperthyroidism. A. B. Reese. New York.—p. 855
Local Quinine Therapy in Old Corneal Opacities.—The encouraging results of quinine therapy in cases of trachoma natu-

rally suggested the use of the drug to Selinger in cases of interstitial keratitis and old corneal opacities resulting from interstitial keratitis and other causes. In cases of interstitial keratitis and old corneal opacities the 2 per cent ointment was used twice a day just before retiring and again in the morning. The ointment causes a burning sensation, which lasts for several minutes but becomes slight after the ointment has been used for several days. There is no cumulative action of the drug. The antagonists and incompatibles of quinine are copper, lead, zinc, mercury and their compounds, ammonia, alkalis, iodides and bromides and their salts, tannic acid and lime water, and should not be used during treatment with quinine. Among the synergists are iron, arsenic and mineral acids. Quinine, besides being a bactericide and an astringent, is a protoplasmic poison, which penetrates deeply into the tissues when applied locally to mucous membranes. It destroys leukocytes and lymphocytes and probably causes the absorption of abnormal tissue elements, such as newly formed connective tissue in the cornea. Quinine bisulphate ointment has a favorable influence on the course of interstitial keratitis and promotes clearing of old corneal opacities.

Dacryadenitis in Hyperthyroidism.—Reese examined the extra-ocular muscles of two patients with progressive exophthalmos following thyroidectomy, whose postoperative basal metabolic rates were minus. In each instance the changes in the muscles were identical with those described by Naffziger. It was noted, however, that the lesions may be limited to one or several of the muscles, therefore, from an examination of one muscle or even of several muscles it cannot be stated that these changes are not present in a given case. Lesions similar to those in the muscles were observed in the lacrimal glands and were histologically identical. The glandular tissue was in all stages of degeneration and was being replaced by edematous fibrous tissue, throughout which were numerous lymphocytes. In places the lymphocytes were aggregated to form foci of considerable size. In other words, there appeared to be no diffuse orbital inflammation nor was there evidence that the inflammation had spread from one site to the other. The observation of dacryadenitis in the cases seems to explain the presence of the enlarged and easily palpable lacrimal glands noted by Naffziger in four of his six cases. It is not uncommon in a case of exophthalmic goiter to see a partial prolapse of the lacrimal gland when the patient looks down and the upper lid is pulled up. An enlargement of the gland may be at least partly responsible for the prolapse, and the enlargement itself may be due to dacryadenitis which in turn causes lacrimation, a not infrequent symptom in cases of hyperthyroidism.

Early Diagnosis of Circulatory Peripheral Diseases.—Graves believes that alert inspection in the diagnosis of circulatory peripheral diseases shows the presence or absence of swelling, variations in color, pigmentation of the skin, presence or absence of sweating, and changes in the texture of the skin. Under the heading of inspection, attention should be called to the diagnostic importance of the angle of circulatory sufficiency. With the patient prone, the extremity should be moved slowly through a range of 180 degrees. If he has circulatory obstruc-

tion, the part will be swollen and cyanotic and show distended veins when dependent. As the part is slowly raised, the cyanosis and swelling will lessen and the prominence of the veins decrease until the angle of circulatory sufficiency has been reached. If the circulatory disturbance should be central and not peripheral, the angle of sufficiency will be close to the horizontal point. In organic peripheral obstruction the angle of sufficiency will be below the horizontal. Palpation is the next logical procedure in diagnosis. The palm of the hand should be able to differentiate any gross differences in temperature between the good side and the affected side or a more than normal drop in temperature as the extremity is palpated from the thigh downward. Palpation should recognize varices, differences in skin elasticity, alterations in skin sweating and any gross differences in pulse volume, particularly of the anterior tibial, the dorsalis pedis and the posterior tibial arteries. The skin is one of the most important heat regulating mechanisms. In the normal individual it will be highest on the trunk and head and progressively lower as one proceeds distally along the extremities. Furthermore, it will be slightly higher in men than in women. In estimating skin temperatures, the following regulatory elements must be considered: exercise, exposure, sweating and position. The skin of the extremities is responsible for heat regulation to a degree considerably more than 65 per cent. The control of this dissipation of body heat is considered to be the main function of the vasoconstrictor-gradient and the normal vasodilation level to 33 C (91.4 F) or more. The skin temperature under standard conditions of exposure should not be more than 10 degrees lower. Skin temperatures, under standard conditions will be proportional to the circulatory rate and volume. The circulatory rate and volume will then be governed by the presence or absence of obstruction, functional or organic, in the adjacent peripheral vessels. Organic obstruction can be determined by the failure of vasodilator procedures to raise the skin temperature.

Gallbladder Disease Simulating Angina Pectoris—

Gould states that the innervation of the gallbladder is derived from the left vagus and from the splanchnic through the celiac plexus, the fibers of which arise from the sixth thoracic to the first lumbar region of the spinal cord. The heart, however, receives its innervation both from the vagus and from the fibers of the thoracic sympathetic system. Yoell shows the innervation of the gallbladder and how disorders here might, by irritating the central portion of the diaphragm and the distal branches of the phrenic nerve, the vagus nerve, the intrathoracic nerves and the celiac plexus, set up impulses that can thus be projected into sensory zones not usually affected by disease in this region.

In cases of cardiac disease, enlargement of the liver is the result of passive congestion but when due to chronic cholecystitis in a cardiopathic patient, one may naturally attribute its size and tenderness to stasis in consequence of the impeded circulation. It is this circumstance that renders the diagnosis of gallbladder disease difficult as a complication of cardiac lesions. A valuable sign of gallbladder disease of corroborative value in some cases is the so called Ewald's area of cutaneous hyperesthesia on the right lower part of the back just internal to the posterior edge of the scapula over the course of the tenth and eleventh intercostal nerves. The heart symptoms seen in gallbladder disease are due to the closely related innervation of the two organs and a toxic myocarditis due to the absorption of toxins from a chronically inflamed gallbladder. The alarming increase of coronary disease and an extremely heart conscious public demand exactitude in diagnosis and not an infliction on the patient of the distressing verdict of angina without the most careful study.

Stimulation of Healing in Nonhealing Wounds—Robinson has found that allantoin, a constituent of the urinary secretions of surgical maggots and of common occurrence in plants and animals, stimulates healing with abundant growth of healthy granulation tissue in slowly healing suppurative wounds. The excretion of this substance into the wound is doubtless one of the factors contributing to the remarkable healing effects obtained in maggot therapy, but the claim is not made that it can be substituted for maggots. Allantoin can be obtained commercially. It is bland, stable and harmless; it has no odor and is nonstaining. The treatment is simple, painless and inexpensive.

Injuries Involving the Ilium—Jahss used the lever principle in treating a case of fracture of the ascending and descending ramus of the pubes, with displacement. Heavy felt padding was placed at the proximal medial ends of the thigh, over the heads of the fibulas and the lateral malleoli. Both lower extremities were immobilized in plaster from the groin to the toes with the knees in complete extension and the feet at an angle of about 90 degrees. The receptors for the turnbuckles were incorporated in the plaster proper. The greatest depth of the turnbuckle was exactly opposite to the direction of the force. All the receptors were placed medially. After the plaster

was absolutely dry, the limbs were moderately abducted. A closed turnbuckle was placed between the proximal receptors and an open turnbuckle, 17½ inches long, between the distal turnbuckles. The closed turnbuckle was then slowly opened. This made the ligaments of the hip joints tense and tended to pull the pelvis open, accomplished by the spreading of the upper ends of the plaster dressings, which acted on the upper ends of the femurs. The distal turnbuckle was then slowly closed. This was the effort end of the lever, the proximal turnbuckle acted only as the fulcrum. As a result of this action of the turnbuckles, the space between the upper ends of the thigh was widened and that between the lower ends of the legs lessened. Just how much force should be applied through the turnbuckles is problematic, but in the author's case the determining factors were the immediate relief of pain in the pubic region on coughing or sneezing and the correction shown in the roentgenogram. The reduction itself can be accomplished in the short time necessary to open one turnbuckle and close the other.

Cartilaginous Inclusions in Rachitic Bones—McMaster found separate islands of cartilage in spongiosa of bones removed at necropsy in a case of healed rickets and made clinical and experimental investigations to determine how frequently this occurs. Clinical material being scarce, the study was made from the material obtained in the reported case and in cases of experimentally produced rickets and from roentgenograms of clinical cases. In the author's case, cartilaginous inclusions in the epiphyses and metaphyses of the long bones, as well as in the ribs and vertebrae, were found. These inclusions, although fairly numerous, showed only faintly in the roentgenograms; hence such inclusions might easily be overlooked in clinical roentgen studies of rickets. In the experimental work on rats, cartilaginous inclusions were found in the metaphyseal, epiphyseal and cortical regions of bone in cases of healed rickets. Microscopic studies revealed that calcification was taking place in many of the inclusions. A few however appeared to be "latent" with slight, if any, evidence of calcification, and contained cells somewhat similar to those seen in a normal zone of proliferation in an epiphyseal plate. This proliferating type of cell in these rachitic inclusions might possibly serve as the "nidus" for benign cartilaginous tumors of bone. In the case of fracture and rickets presented, the roentgenograms, taken after healing had occurred, showed a large expanded circumscribed area in the cortical region of the lower metaphysis of the femur suggestive of a rachitic cartilaginous inclusion. This disappeared two years later.

Experimental Encephalomyelitis Accompanied by Myelin Destruction—Rivers and Schwenker observed that the repeated intramuscular injections of aqueous emulsions and alcohol-ether extracts of sterile normal rabbit brains in some manner produced pathologic changes accompanied by myelin

destruction in the brains of seven of eight monkeys (*Macacus rhesus*). Eight control monkeys remained well. Cultures from the involved brains remained sterile, and no transmissible agent was demonstrated by means of intracerebral inoculations of emulsions of bits of the brains into monkeys, rabbits, guinea-pigs and white mice. The character of the lesions observed is such that one would suspect that an infectious agent caused them. Nevertheless the presence of such an agent could not be demonstrated by means of stains and cultures. Inoculation of monkeys, rabbits, guinea-pigs and mice with emulsions of the involved brains failed to disclose a transmissible agent. The fact that the control animals remained well seems to indicate clearly that the pathologic changes which occurred in the brains of the treated monkeys were in some manner either directly or indirectly, brought about as a result of the repeated intramuscular injections of aqueous emulsions and alcohol ether extracts of sterile normal rabbit brain. The relation of their results to the paralysis accompanied by destruction of myelin that is known to follow the repeated injections of emulsified rabbit brain containing fixed rabies virus used in the vaccination of human beings against rabies is not clear to the authors. Each of their animals received more injections than are used in the Pasteur treatment, the smallest number being forty-six and the largest eighty-five. Further work is under way to determine the nature and the mechanism of the production of such lesions.

Bacillary Dysentery in Children—Denison and deHoll state that the acute diarrheas of infancy should primarily be divided into gastro-intestinal infections almost invariably due to dysentery bacilli and gastro-intestinal disturbances of function from numerous causes. Before present classifications can be improved, bacillary dysentery must be completely removed from the other types. Infectious diarrheas are bacillary dysentery and should be so designated. Diagnosis should be supported by examination of the stools microscopically for pus and chemically for blood. The finding of these with few very

obvious exceptions, always means bacillary dysentery. The authors isolated 159 cultures showing fermentations characteristic of dysentery bacilli in the course of the study of thirty-five cases of infectious diarrhea in children and infants. Of 142 of these tested, 116 were agglutinable in antisera for stock strains. Of seventy-two agglutinable cultures tested, fifty-three were identified by complete and fifteen by partial absorption of agglutinins in antisera. Isolated strains corresponded to Y (Hiss), Mount Desert, WX, V and Sonne strains. An isolated strain (from one to six days) was identified by agglutination absorption with fifteen strains from seven patients. Its antiserum was not appreciably affected by stock strains. It appears to be a member of the Flexner group, though not identical with any of the fifteen stock strains studied. Dysentery bacilli (Flexner group and Sonne) were isolated from twenty-six patients with infectious diarrhea (74 per cent). From each of two patients two different strains were recovered. Dysentery bacilli were recovered from 63 per cent of the stools from which cultures were taken during the first five days of illness. After the fifth day the chances for recovering the organisms rapidly diminished, even though the majority of the stools continued to show blood and pus for fifteen days longer.

Tuberculous Immune Bodies in Nontuberculous Persons—Baker and Wetherby tested the blood of 100 consecutive adult patients with chronic arthritis with the complement fixation test for tuberculosis both before and after a course of intravenous vaccination with streptococci. Fifty-one of the patients showed a positive skin test with old tuberculin and a negative complement fixation test before the institution of any therapy. Of these twenty-six reacted positively to the complement fixation test after the intravenous streptococcus vaccination. This would indicate that specific tuberculous antibodies may be exfoliated into the circulation of patients who at some previous time had had a tuberculous infection as indicated by the positive skin test. If antibodies indicate in any way resistance against tuberculosis, the results would suggest a persistent protection against tuberculosis long after the original infection. Forty of the total patients showed a negative Mantoux test and a persistent negative complement fixation test for specific tuberculous antibodies after the intravenous streptococcus vaccination. The occasional positive complement fixation test for tuberculosis in apparently normal persons may be explained in some instances on the basis of a nonspecific exfoliation of antibodies produced during a previous tuberculous infection.

Fever Therapy in Rheumatic Carditis—Sutton and Dodge present sixteen cases in which the diagnosis of active rheumatic carditis was justified. The patients were given artificial fever therapy produced by the intravenous injection of triple typhoid vaccine for a concurrent chorea. In nine of these patients, all clinical signs of activity had subsided by the end of treatment. In the others, signs were gone in from a week to ten days following the end of treatment. Two cases are presented of subacute rheumatic carditis without chorea. The

patients were given artificial fever therapy produced by radiant energy. In one patient the signs of rheumatic activity cleared immediately following one treatment but recurred again to a much lesser degree eight weeks later. She was given a second fever treatment and has shown no clinical evidence of activity since. The second patient improved following one treatment, but the signs of activity did not completely subside until after a second treatment two weeks after the first. The authors suggest that the use of fever therapy in forms of rheumatic fever other than chorea deserves further study.

Soy Bean Milk in Infant Feeding—Rittinger and his associates give the results of soy bean milk feeding over a period of three and one half years in 205 infants who were fed this "milk" over variable periods. Growth and development, weight gains and their general progress point to the adequacy of the milk as a prophylactic food. The preparations used have been shown to contain adequate amounts of the essential vitamins, and metabolic investigations have demonstrated a relatively high biologic value. Soy bean milk in combination with various percentages of skimmed milk protein affords a food of high nutritional availability. Blood studies have shown a normal range of calcium and phosphorus (serum), and roentgenologic studies demonstrate good bony development and texture with few exceptions. Signs suggestive of rickets in a few instances have not been corroborated clinically or serologically. The stool flora shows a high percentage of gram positive organisms thus resembling those of breast-fed infants. Soy bean milk is of practical value in the dietetic treatment of infantile eczema and in the treatment of constipation in infants by virtue of the roughage factor.

Vascular Changes in Experimental Atelectasis—Adams and his associates state that massive atelectasis of the lung is attended by an apparent increase in the vascularity of the tissue (passive congestion). Therefore the volume flow of blood in atelectatic tissue is decreased. In chronic atelectasis there is a gradual disintegration of the alveolar walls with the formation of channels leading from the circulating blood stream through the alveoli. This circulating blood reexpands the alveoli and may extend up the air passages into the smaller bronchioles. This phenomenon was first observed near the periphery of the lung parenchyma and round the larger bronchi. It was first seen in atelectasis of a duration of four weeks and slowly increased in amount. It was never observed to replace the usual architecture of atelectatic tissue in all parts of the section. Massive atelectasis of a duration of many months was reinflated by a pressure of 35 mm. of mercury. The reflation was incomplete and a lung lobe could be increased to only one half or two thirds of its original size. There was a considerable degree of laceration of the alveolar walls within the lung lobe due to reflation. Only a part of the dilated blood-filled spaces was entered by the air introduced. A moderate amount of fibrous tissue proliferation occurred in atelectatic tissue. This was insignificant as compared to the marked fibrosis attending infected atelectatic lobes. Decreased volume flow of blood through an atelectatic lung was demonstrated by injection of the pulmonary arterial system, by blood oxygen determinations and by bleeding atelectatic and normal lobes of a similar size. Positive pressure insufflation of the aerated lung diverted a considerable quantity of blood from the aerated to the atelectatic lung. The amount of flow through an atelectatic lung with the aerated lung under a positive pressure insufflation

of 35 mm of mercury was about 25 per cent when determined by bleeding of two similar lobes and about 32 per cent when estimated from blood oxygen determinations. These figures would be considerably reduced if accurate measurements could be obtained with normal intrathoracic pressures prevailing. Oxygen saturation of mixed arterial blood was little influenced by the production of atelectasis of the left lung. This suggests a very low percentage volume flow of blood through the atelectatic lung.

Merthiolate Solution in Treatment of Tuberculous Empyema—For the last year and a half Woodson and Mullen have used merthiolate solution (sodium ethyl mercurithiosalicylate) in the treatment of eighteen cases of tuberculous empyema occurring as a complication to artificial pneumothorax. All except two have proved to be tuberculous empyema by laboratory methods, either by direct smear for the tubercle bacillus or by guinea-pig inoculation. In using the merthiolate solution the authors have been able to clear up the empyema in a number of these cases and at the same time maintain the artificial pneumothorax. Those on treatment at the present time show a favorable tendency toward clearing. The time required for complete clearing of the empyema was from three to seven months and in these cases it has not recurred except in one terminal case. The procedure has been to remove the pus thoroughly from the pleural cavity by direct aspiration and irrigate it at weekly intervals with merthiolate solution 1:10,000 or 1:5,000 in physiologic solution of sodium chloride, until the return is clear. From 20 to 100 cc of the solution is left in the pleural cavity and the intrapleural pressures are equalized following the treatment. In five cases concentration of the solution was increased to 1:2,500, with only one reaction in which an uneventful recovery was made. The fluid in fourteen cases was frank pus, creamy or greenish in appearance. In the remaining three cases it was definitely turbid. Soon after starting the treatments, the character of the pus became definitely thin and assumed a light brownish color before finally disappearing. In three cases that were secondarily infected with staphylococci the cultures completely cleared in from three to four weeks. The results in these cases together with the remarkable results in a streptococcic empyema case suggest the advantage of merthiolate in nontuberculous empyemas.

Chronic and Delayed Tetanus—Bennett and Grodinsky present a case of tetanus with a delayed incubation period of 100 days, which showed a chronic form of tetanus for five weeks before treatment. The delayed incubation period was undoubtedly caused by a prophylactic dose of antitoxin but illustrates the fact that an injection of 1,500 units is not fully protective, especially if a foreign body remains in the local wound. Also tetanus may assume a chronic form in the presence of a foreign body. The case further stresses the need for radical treatment of a local lesion. All suggestive wounds should be explored and treated with antitoxin. The patient would probably have recovered by treatment of the local lesion alone. In the general treatment of tetanus, the authors feel that most patients are over-treated. A large curative dose of antitoxin should be given, followed by antispasmodics, barbiturates, such as amytal or tribromethanol, and magnesium sulphate intraspinally or curarine in sufficient amount to control the motor spasms. They doubt whether repeating the doses of antitoxin does much good, provided the focal lesion is eradicated. If the patient will not recover under this management, he probably cannot be saved by massive doses of antitoxin.

Virus That Causes Lymphocytic Choriomeningitis—Armstrong and Wooley have isolated two strains of virus similar clinically, pathologically and immunologically to the strain previously described by Armstrong and Lilie (1934), which was encountered during the transmission, in monkeys, of infectious material from an individual who died at St. Louis during the 1933 encephalitis epidemic. Spontaneous infection among the authors' stock monkeys has been demonstrated by the isolation of the virus from a noninoculated monkey and by the demonstration of specific antibodies in the serums of five of forty-four such animals. The possibility that the virus may affect man is suggested, since two of the recovered strains are possibly of human origin. The ready and even spontaneous infection of monkeys with the virus, together with the fact that human serums (three from 166) possessing potent specific antibodies for the virus have been encountered points in the same

direction. As previously noted, the disease in monkeys resembles the human ailment designated as lymphocytic or aseptic meningitis, and serum collected from a person eleven months following a clinical attack of this disease gave strong protection against strains of the experimental virus. The establishing of immunity in the serum of an exposed subject giving no history suggesting this disease, however, indicates that immunity may develop in the absence of symptoms referable to the central nervous system.

Bacterial Infarction of Femur in Rabbits—Kistler injected a hemolytic strain of *Staphylococcus aureus*, obtained from a culture taken from the blood stream of a man with a subperiosteal abscess and fatal septicemia, through the principal nutrient arteries of the femur of rabbits between 3 and 8 weeks of age. The suspension was directed through the deep femoral artery. Material introduced into the principal nutrient artery of the shaft was directed almost entirely to the medullary canal of the diaphysis. Each rabbit received from 0.2 to 0.6 cc. of the agglutinated living or killed suspension and died or was killed from twelve hours to forty-eight days after operation. A few were injected with nonagglutinated living staphylococci, but all died within two days. Several of the animals injected with living organisms died within twenty-four hours after operation, others lived as long as seventeen days, depending on the mass injected and the viability of the cocci. A pure growth of staphylococcus, similar to the strain injected, was obtained from joints with exudate that were contiguous with the injected femurs. Gross examination of femurs injected with agglutinated suspensions of killed *Staphylococcus aureus* demonstrated infarction and subsequent changes similar to those observed after occlusion of the medullary blood vessels by charcoal and significant of interference with growth of the bone, of ability to bear weight and of osteogenic reaction within the periosteum. Histologic preparations of femurs that received killed agglutinated organisms through the nutrient artery to the shaft demonstrated infarcts and anemic necrosis confined almost entirely to the metaphyses and endosteum. The smaller and more recent infarcts were wedge shaped and were situated

in the tissues immediately beneath the columns of epiphyseal cartilage without marked changes in the medullary tissues of the diaphysis or of the adjacent bony epiphysis. Large infarcts occupied the entire metaphysis, and in these the necrosis was most marked about the columns of ossifying cartilage toward the center of the growth region. Infarcts present for six days or longer showed a separation and reorganization process, present on all sides of the wedge except at the base beneath the epiphyseal cartilage plate. The primary site of embolic infarction of the femoral epiphyses was beneath the articular or other cartilage and was similar to metaphyseal infarcts beneath epiphyseal lines of the diaphysis. Necrosis in the femurs produced by carbon emboli was more marked and extensive in the medullary tissues of the shaft than after the injection of clumps of dead cocci. The gross alteration in the size and contour of the femurs infarcted with living agglutinated suspensions of *Staphylococcus aureus* were similar to but more marked than in those that received injections of killed organisms. Several joints contiguous to infarcted metaphyses contained exudate from which a pure culture of the organism was obtained. Microscopic examination demonstrated anemic necrosis, according to the pattern described for bland infarction, combined with exudative inflammation. The latter agent intensified the hemorrhages and necrosis and elicited a marked infiltration of polymorphonuclear leukocytes about the septic infarct. When the metaphyseal abscesses were sufficiently large to extend to the cortex, there was exudate in the canaliculi of the bone and occasionally beneath the periosteum. Necrosis of the subperiosteal tissues elicited a cellular and fibrous tissue reaction of the periosteum, dead bone absorption and new bone formation. Complete separation of the epiphysis occurred when the walling off process at the periphery of the cartilage plate was unable to maintain viable tissues between epiphysis and diaphysis. The walling off and reorganization process in septic infarcts seemed to proceed more slowly than those produced by bland *staphylococcus* emboli. Septic necrosis produced more new cortical and spongy bone, greater injury to the epiphyseal plates and more disarrangement of the medullary tissues of the metaphyses than did the aseptic infarcts. The new bone formed outside infarcts of the endosteal tissues was always well delimited from the dead cortical bone by cellular fibrous tissues containing osteoclastic giant cells but sequestration was not observed.

Sympathectomy Preliminary to Obliteration of Popliteal Aneurysms—Bird performed lumbar ganglionectomy as a preliminary procedure to the obliteration of a popliteal aneurysm, thereby avoiding the constrictor action of the sympathetic fibers on the collateral arteries during the dangerous early postoperative period. In the same way advantage should be derived from sympathetic ganglionectomy or sympathetic block carried out before or immediately after operations or injuries that involve obstruction or threatened obstruction to large arteries of the extremities. The rationale for these procedures is contained in the work of Mulvihill and Harvey. In suitable cases the apparatus of Herrmann and Reid for passive vascular exercise should accomplish the same result without interference with the sympathetic fibers themselves.

Obstructive Lesions of Uterus and Their Complications—Curtis emphasizes the frequency of obstructions of the cervix and presents the important pathologic changes that are encountered in the more serious cases, instances of which are given. He believes that the various therapeutic procedures employed in the treatment of lesions of the cervix are more important than any other factor in the etiology of cervical obstructions. Endocervicitis is also of importance in the etiology, and in the majority of cases of serious stricture there is a history of an inflammatory process as well as of instrumentation. However the absence of a history of infection or of instrumentation does not always give assurance of a patent cervical canal and adequate uterine drainage. Fibrotic constriction of the cervical lumen is much more serious than simple obstruction by adhesions. If drainage is not free, pocketing of the cervix may occur immediately above the fibrous obstruction. A metaplasia of the columnar epithelium into squamous epithelium has been found in the roughened pocketed endocervix above cervical strictures. A similar metaplasia has

occurred in the pocketed endometrium above a cervical stricture. Irritation from retained secretions may be a factor in stimulating the metaplasia. In the presence of leukoplasic squamous cell metaplastic tissue bathed in retained menstrual fluid and debris, a possible explanation is found of the frequent incidence of squamous cell cancer of the endocervix and adjacent endometrium. Tumorous nodulations of the endocervix and lower portion of the uterine segment are a less common cause of uterine obstruction. The effects of damming back of uterine secretions and menstrual blood may be far reaching—perhaps important in the etiology of endometrial polyps, adenomyosis of the uterus, pelvic endometriosis and back pressure inflammatory processes in the pelvis. The relationship of obstructive retention to the development of intra-uterine cancer is a problem that merits further study.

Thrombophlebitis and Embolism—This lists the following as contributing causes of pulmonary embolism in thrombophlebitis: 1. Limited damage or destruction of the endothelial lining of a vein leading to thrombus formation provides insufficient attachment of the clot to the wall of the vein. 2. Inactivity of the patient results in the formation of large coagulation stagnation thrombi instead of the limited solid mixed deposition thrombi. 3. Coagulation solutions for intravenous injections produce unattached coagulation clots. 4. Suppurative infection, either caused by direct contamination from surrounding tissues or hematogenous in origin is followed by disintegration and loosening of the clot. 5. Direct trauma or massage of the thrombotic area may loosen and detach a portion of the thrombus. Pulmonary embolism occurs most frequently in bedridden debilitated and cardiac patients. With limited attachment of the thrombus to the wall of the vessel, the deficient circulation of blood aids extensive secondary red stagnation thrombus formation. These are easily dislodged and carried away in the circulation. Although thrombophlebitis produced by injection of chemical irritants, trauma or infection is indistinguishable clinically, there may be a marked difference pathologically. The possibility of detachment of a thrombus and embolism formation depends on the pathologic type of thrombus present. Thrombophlebitis of the extremities, irrespective of the cause is less likely to be followed by pulmonary embolism than thrombosis in other locations. In the injection treatment of varicose veins, proper selection of cases for injection, skilled technique and complete cooperation of the patient after injection in continuing routine daily activities will lessen the frequency of pulmonary embolism.

Hyperinsulinism, Hypoglycemia, Subtotal Pancreatectomy—Thomason reports a typical case of hyperinsulinism with hypoglycemia, representing one in which there was evidently a hyperfunctioning pancreas, no tumor being present, in which a subtotal pancreatectomy was performed. The removal of the greater portion of the pancreas produced favorable results quite comparable to those cases of cure reported in which a tumor was found and surgically removed from the pancreas. The patient made an uninterrupted recovery. Two days after the operation the blood sugar was 138 mg and five days later it was 111 mg. From then until the present, on a normal diet, even low in starch and without sweets, the blood sugar has ranged well within normal limits—from 87 to 91 mg—and the patient reports himself as feeling very fit.

Tuberculous Disease in Childhood—Blacklock observed 2500 consecutive necropsies on children in whom a thorough search for evidence of tuberculous disease was made. The peak incidence occurred in the third year. Girls at all ages were more often affected than boys. The yearly incidence of positive tuberculin tests in a large number of children who came to necropsy practically corresponded with the incidence of tuberculous lesions found. The tuberculous lesions were the cause of death in 240 (95.2 per cent) of 252 subjects less than 3 years of age and in ninety-three (74.4 per cent) of 125 over this age. In five cases there were double primary sites of infection, one in the thorax (responsible for death) and one in the abdomen. The primary site of infection was most commonly thoracic and then abdominal, cervical or unknown. Primary thoracic tuberculosis occurred in 63.4 per cent of the tuberculous cases and, relative to the number of necropsies, had a higher incidence in subjects more than 3 years but was more frequently fatal under this age. Only 0.6 per cent of the children less than 3 and 9 per cent over this age with primary thoracic tuberculous lesions did not die as a result of the tuberculous infection. Primary lesions of the lung of a more acutely progressive type were found in children less than 3 years than in those over, while evidence of arrested lesions was commoner in the older children. The primary lesion of the lung was always associated with tuberculous tracheobronchial glands and was rarely the sole tuberculous lesion in the lungs. Most of the children with primary intrathoracic tuberculosis died of generalized infection, and this was slightly commoner in children less than 3 than in those over. In 149 children who died, the infection was due to human strains in 143 and bovine in six (4 per cent). There was a slight higher proportion of bovine strains in children in the first three years of life than in those between 3 and 13. From children not dying as a result of the tuberculous lesion, five human strains were isolated. In 123 (32.4 per cent) investigated, the primary site of the tuberculous infection was abdominal. The relative incidence of primary abdominal lesions to the total necropsies was greater in children more than 3 years of age, but more deaths resulted from the abdominal infection in the younger children. Intestinal ulceration was present in twenty-two abdominal cases, such lesions were always fatal and were more common in children less than 3 years of age. In 101 instances there was no tuberculous intestinal lesion but the mesenteric glands were caseous. In 74.4 per cent of children less than 3 and 29.3 per cent of those over this age generalization of the infection caused death. Tuberculous disease localized to the abdomen caused more deaths than similar disease confined to the lungs. Of the bacilli isolated from the abdominal cases in which death

resulted from tuberculosis, eleven were human strains and forty-seven (81 per cent) bovine. From children not dying as a result of the abdominal disease, two human and thirteen bovine (86.7 per cent) strains were obtained. The prognosis in primary abdominal tuberculosis is better than that in primary thoracic tuberculosis, but the diagnosis of the abdominal disease in the early stages is often very difficult. Primary tuberculosis of the cervical glands occurred in only eight (2.1 per cent) children, of whom two did not die as a result of the lesions, the remainder dying of generalization of the disease. From this group three human and three bovine strains were isolated. In seven no primary source was found, and three human strains were obtained from these.

Natural Cure or Collapse Therapy in Treatment of Pulmonary Tuberculosis—Jaquierod suggests that the patient with a recent pulmonary lesion should be given the chance of improving with simple medical means, which in a number of cases is all that is necessary to obtain a complete cure in the minimum of time and with the minimum of organic and functional disturbance. The process of healing in these cases in no way differs from that brought about by collapse therapy, except that the latter is more certain and more thorough. Since it is admitted that a pneumothorax should be induced when it is seen that the patient is not improving with simple medical treatment it would seem that the chronic fibroid case encountered so often formerly should not be in evidence today. This would be so if pneumothorax gave perfect results, but this is far from being the case and the author believes that he does not exaggerate when he says that the chronic fibroid case is as common today as before the introduction of collapse therapy. When confronted with a case of recent disease, and one weighs in the balance the advantages of treatment by rest alone and treatment by artificial pneumothorax, it is not right to infer that the one offers but a mediocre chance of cure whereas the other gives the patient almost a certainty of rapid and complete recovery, for in a considerable number of cases treatment by pneumothorax will only mean a series of painful procedures continued over a period of years. The author believes that the custom which would enforce collapse therapy at once for all cases of pulmonary tuberculosis is not justified, for there are cases which reap the greatest possible benefit by being given the opportunity of obtaining a lasting cure by simple and natural means.

Study of Acute Mastitis of the Puerperium—In 100 cases of acute puerperal mastitis, Moon and Gilbert observed that three-fourths of the cases occurred in primiparas. Pre-existing infective foci, hemorrhage during labor and albuminuria of pregnancy do not appear to be predisposing causes. Intervention with normal labor by induction, cesarean section and other obstetric operations are of considerable importance. A comparison of the frequency of acute mastitis in hospital and district patients shows that the disease is essentially one of institutions and throws some light on various etiologic factors considered. A study of the incidence of acute mastitis at the authors' hospital over a period of nine years shows that there has been a general increase, most marked since 1931 and reaching a maximal peak in the early part of 1934. There is some tendency to a periodic variation, the crests occurring for the most part over a period covering the last two and first two months of the year. The onset of pyrexia is by far the most common in the second week, on or about the eleventh day

Unilateral mastitis occurs twice as often as bilateral mastitis. Only one fourth of the cases of acute mastitis resolved. There is an apparent variation in severity as well as in incidence. The average time of operation is the twentieth day of the puerperium. Delayed operation, after awaiting complete localization, is preferred to prompt incision. The importance of cracked nipples as an etiologic factor tends to be exaggerated. Three different methods of local prophylactic nipple treatment yielded no alteration in the incidence of acute mastitis. *Staphylococcus aureus* was the cause of all the breast abscesses examined bacteriologically. The average duration of indoor hospital treatment for all cases of acute mastitis (resolved and suppurating) is about thirty-five days. Among the infants of these patients there is a mortality of 3 per cent, and a morbidity of 8 per cent due to intestinal infection presumably from the mother's milk. The baby should be removed from both breasts as soon as a definite diagnosis of acute mastitis is made. From the bacteriologic investigations on the milk of normal lactating mothers, it appears that *Staphylococcus albus* does not cause acute mastitis but that *Staphylococcus aureus* is the essential organism. The presence of *Staphylococcus aureus* alone does not necessarily mean an acute mastitis, and other factors are necessary: a virulent strain of organism, lack of local immunity of the breast and alterations in the chemistry of the milk are contributing causes. Future lactation is not interfered with in the great majority of cases after an abscess of the breast; the causes of failure to feed subsequent babies are retracted nipples, painful scars and deficient secretion.

Autogenous Infection in Relation to Puerperal Morbidity—Ford made an attempt to assess the resistance to infection in pregnancy and selected the Dick test for trial as being readily applied. A series of 220 patients were tested at about thirty-six weeks of gestation and again after delivery. Cervical smears were taken in every case of a positive result. Not one of the cervical smears produced a culture of streptococci. Six cases of puerperal pyrexia occurred. All these patients had exhibited negative antenatal and postpartum reactions. The pyrexia varied from a mild to a fairly severe degree. The patients made satisfactory recoveries with the exception of the one suspected of having pulmonary tuberculosis who is understood to be still under observation for tuberculosis. Ten patients who had exhibited antenatal negative and postpartum positive tests were requested to attend again at varying periods after their confinements, for further tests. Only six attended, and two did not return for the reading of the result. All four who appeared exhibited negative results. It is difficult to determine the correct interpretation in the cases (4.5 per cent) that exhibited negative reactions before labor, positive ones soon after it and again negative ones later. If it is assumed that a negative reaction to the Dick test indicates the presence of a certain minimal amount of antitoxin in the circulation, it is conceivable that these patients sustained mild infections but that the amount of antitoxin available was in each case adequate without necessitating any such reaction as would be evidenced by noticeable rises of temperature or pulse rate, and that this balance in hand of antitoxin was gradually restored later. Streptococcal forms were, however, not found in cultures from the cervixes of any of these patients and material for such cultures was taken immediately after the reactions were noted. Alternatively, it is possible to consider that the actual physical strain of labor itself in these patients produced temporarily a generally lowered resistance to infection. Such a theory as this would account for the rapid development of severe general infections on occasion without obvious definite cause, considering that latent infections are known to exist as supported by the cases quoted showing that coliform organisms may be responsible for severe infections. Some extragenital source of infection may be responsible for a proportion of the puerperal variety.

Intravenous Use of Solution of Pituitary in Obstetrics—Baron states that, in properly selected obstetric cases, solution of pituitary in doses of 1 minum (0.06 cc) has been safely administered intravenously. The best results were obtained in initiating labor in patients in whom the membranes had ruptured, and in secondary inertia either before full dila-

tation or with full dilatation when the head was on the perineum. In the latter cases the use of the forceps was obviated. Good results have been obtained in cases of postpartum bleeding and after cesarean section. Its use for obstetric diagnosis—fibroids and extra uterine pregnancy, for missed abortion and after reduction of the inverted uterus is suggested. It has been unsuccessful (in the author's experience) in starting labor before term, especially with intact membranes, even in conjunction with castor oil, quinine and hot enemas. There are important contraindications to the use of the drug, which, if observed, will prevent its falling into disrepute.

Pneumococcal Pneumonia—The nineteen cases of pneumonia that Davies and his co-workers selected for serum treatment were those in which symptoms were severe or the risk poor. Only two ended fatally—one from meningitis after an apparent recovery and the other from a bilateral deep-seated empyema. Both of these had shown an initial response to serum. The group includes three cases treated on the sixth day: a positive blood culture was found in four, though in the two patients that died the blood was sterile. It speaks favorably for the potency of serum that the four showing a positive blood culture recovered, and of these one was positive as late as the sixth day. The effect of the serum on the symptoms was undoubted. In the early case it was immediate and the febrile period was obviously shortened. The respiratory embarrassment was greatly allayed although the signs of consolidation remained or in some cases actually progressed, even though the crisis had occurred and the patient was afebrile. The cases showed definite symptomatic benefit, and, although this was more obvious when the serum was given within the first three days the authors concluded that some effect was obtained when it was given later. If antipneumococcus serum is specific they think it should not be withheld from patients desperately ill on the sixth or seventh days, as it may prolong life for an extra day and thus allow a crisis to be established. They regard any case of type I pneumonia as showing need of serum if the condition is severe and the prognosis uncertain. Moreover, since serum may 'abort' the disease when given early, its use should always be considered in cases seen during the first three days, if it shortens the febrile period it will make extension or relapse less likely.

Sterility and Psychoneuroses Following Lumbar Sympathectomy—Hurst states that lumbar sympathectomy should be performed only in males when a condition is present which is likely to receive sufficient benefit to compensate for the unavoidable sterility that will develop. He doubts whether it is ever justifiable in boys with Hirschsprung's disease. In the eight cases that he has seen since the war, nonsurgical treatment led to improvement just as great as that claimed for sympathectomy. The operation should never be performed on an adult male without his written consent after he has been told of the effect it will have on his sexual functions. If he knows what to expect he is also very unlikely to develop psychoneurotic symptoms as a result of the loss of emission. The author presents two cases in which the impairment in sexual functions following lumbar sympathectomy in men was followed by serious psychoneurotic symptoms.

Hemochromatosis—Ramage and Sheldon examined the tissues from five cases of hemochromatosis. The diagnosis was established in all cases at necropsy. They observed that there is an increase of iron in all the tissues of the body, with the exception of the blood, brain and colon, the two latter of which are, however, subject to individual exceptions. In certain organs the amount may be enormous especially in the liver, pancreas, lymph nodes, thyroid, salivary glands, pituitary, choroid plexuses and heart. The increase over normal appears to be greatest in the pancreas. The somatic muscles share in these deposits of iron. The total amount of iron deposited in the body by the time of death appears to vary from about 25 Gm to from 45 to 50 Gm. There is a slight increase of the total sulphur in certain of the tissues, especially in the alimentary canal. This is probably related to the deposits of hemofuscin. Spectrographic examination confirmed the results of previous chemical analyses in showing that there is an increase of copper in the liver. This increase applies to all the tissues with the exception of the kidney, small intestine and omentum. The general order of increase is between two and three times the normal. Certain of the tissues have an increase of calcium, which is best seen in the liver, thyroid, striated muscles and pancreas. Most of the tissues show disturbances in the behavior of both sodium and potassium, these metals usually swinging in opposite directions. The manganese content of the liver is about one-fourth the normal. No unusual elements were found.

Murmurs Produced by Auricular Systole—The records of the heart sounds in a case of exophthalmic goiter with partial heart block that Bramwell presents show that the initial vibrations of the first heart sound in normal cycles bear the same time relation to the P wave in the electrocardiogram as do the vibrations of the auricular phonogram to the blocked auricular beats. These two series of vibrations are also similar in form. When the PR interval is prolonged the complete series of vibrations in the auricular phonogram precedes the larger vibrations of the ventricular phonogram, but when the PR interval is of normal duration the two series of vibrations overlap. These observations prove that, in the author's case, the initial vibrations of the first heart sound are produced by the auricle and not by the ventricle. It is suggested that the initial vibrations seen in records obtained from normal subjects may also be attributable to auricular systole. These initial vibrations are, however, usually of such small amplitude that they fail to reach the threshold of audibility. The author suggests that the similarity between the first heart sound in hyperthyroidism, in certain athletes, in some cases of congenital heart disease and in some patients with high blood pressure, and the first heart sound and presystolic murmur of mitral stenosis, may be due to an increased velocity of the blood flow through the mitral orifice when the auricular muscle is hypertrophied. The late development of the auricular sound suggests that it is due not

entirely to a muscle tone but in part at least to vibrations set up by the blood ejected by the auricle. Records of heart sounds and murmurs in two cases of mitral stenosis complicated by partial heart block showed that the time relations of the auricular systolic element of the mitral murmur were strictly analogous to those of the auricular component of the first heart sound in the present case of hyperthyroidism. There is a striking variation in the intensity of the auricular systolic murmur in different cycles of these records. When auricular systole occurs early in diastole the murmur is loud, but when it occurs at the end of a prolonged diastole it may be so faint that it fails to reach the threshold of audibility. Its absence in cycles following a blocked auricular beat is explained by the inability of the engorged ventricle to accept the auricular output. Summation of the terminal vibrations of the auricular systolic murmur and the initial vibrations produced by ventricular systole may account for the accentuation of the first heart sound in patients with mitral stenosis.

Hereditary Pseudohepophilia—Handley and Nussbrecher discuss the literature on hereditary bleeding in women, present three such cases of pseudohepophilia and state that a discussion of the mechanism of bleeding in pseudohepophilia would appear to be useless so long as the major problems of the coagulation of normal blood remain matters of controversy among physiologists. Von Willebrand and Jürgen's work points to some abnormality of the platelets being the most likely cause of the prolonged bleeding, but more evidence must accumulate before this hypothesis can be proved or disproved. The diagnosis of pseudohepophilia must rest on an adequate family history and unequivocal symptoms of bleeding, supported by complete blood investigations. Von Willebrand states that in pseudohepophilia clotting time is normal and bleeding time prolonged. The reverse is true of the cases that the authors describe, and their observations tally with those of true hemophilia. But these two investigations are subject to many pitfalls, and too much reliance cannot be placed on isolated readings. The clotting time varies in the same individual from time to time, and the bleeding time, owing to the lack of standardized technique, at present needs considerable experience in the interpretation of results. To conclude the authors emphasize that two possibilities have to be weighed in considering their study. It may be an example of pseudohepophilia, or it may be an example of hemophilia with the production of the first homozygous females recorded. They rather believe the former view owing to the evidence of the Mampel tree and Wightman's family, together with the direct transmission of bleeding seen in the earlier part of their family tree. Those who would support the latter view must be prepared to accept the occurrence of bleeding in homozygous females.

*Alkali Reserve and Ionic Acidity of Human Bile Removed by Duodenal Tubage M. Chirav and P. Firmin—p. 233
Stomach After Surgery Roentgenologic Study M. C. Gross—p. 243

Acid-Base Equilibrium of Human Bile—Chirav and Firmin used the Van Slyke method to determine the free and combined carbon dioxide content of normal bile. In order to determine the limits of variation of biliary alkali reserve, the absorption of carbon dioxide was experimentally studied. Bile from supposedly normal persons, removed by biliary tubage, preserved under oil in the presence of traces of antioxidant substances and kept in the refrigerator, was used. As a result of these studies it appears that bile is a physicochemical system somewhat similar to blood. The level of biliary alkali reserve reported is not absolute and relates only to the samples under observation. In general, zones of alkalosis and acidosis similar to those in the blood are indicated. The number of complicating factors, however, does not facilitate the interpretation of the observations.

Gold Treatment of Pulmonary Tuberculosis—Pierre-Bourgeois and his co-workers deplore some of the uncritical enthusiasm for the treatment of tuberculosis with gold salts. The attempted prophylaxis of pulmonary tuberculosis by this means is especially unjustified. They made careful observations on 850 adult patients with established pulmonary tuberculosis treated by gold salts in conjunction with sanatorium care. They concluded that the psychic effect was good and that gold salts could be useful in addition to this effect. Clinical and roentgenologic improvements occurred in some patients and, although transitory, were nevertheless real. Gold treatment, however, must never impede other more effective antituberculosis procedures. Finally, they believe that the appearance of any therapeutic accident indicates immediate and final discontinuance of gold treatment.

Calcium in Treatment of Vagosympathetic Dystonia of Upper Air Passages—Riccitelli and Franchini consider that spasmodic rhinitis belongs to a group of pathologic reflexes of the upper air passages originating in disturbances of the endocrine and the autonomic nervous systems. These reflexes frequently develop in women between 15 and 20 years of age, when the rupture of the sympathetic-parasympathetic equilibrium is frequent. The authors state that there is a relation between the ionic equilibrium of the blood, with regard to calcium and potassium ions and that of the autonomic nervous system the rupture of which results in the development of neuromuscular excitability. They consider the great variety of endocrinologic disturbances of vagosympathetic origin a neurosympathetic lability with hyperexcitability of the whole autonomic nervous system rather than a vagotomy or a sympathectomy, pure forms of which do not exist. The constant presence of high values of calcium and potassium in the blood

indicates that a vagosympathetic dystonia exists. Whether the condition is of sympathetic or of vagal predominance, calcium gluconate gives satisfactory results, especially if given with opotherapy or with a general treatment, according to the etiology of the disease. Calcium seems to have no specific action in moderating the parasympathetic or in stimulating the sympathetic, but rather a restorative action on the equilibrium of the two segments of the autonomous nervous system. In cases of spasmodic rhinitis there is a disequilibrium of the calcium and the potassium in the blood, which is restored by the calcium as proved by the reestablishment of the constants of Krauss and Kylin. The restoration of the ionic equilibrium of the blood is followed by that of the equilibrium of the autonomous nervous system and results in immediate improvement of the pathologic respiratory and nervous symptoms.

*Gastric Surgery K. O. Peters—p. 651
Surgery of Perforation of Gastric Duodenal Ulcer O. Orth—p. 674

Prognosis of Cancer of Breast—Siemens' material consists of 508 cases of carcinoma of the breast in which radical operations were performed at the surgical clinic of the University of Kiel (Professor Anschütz) between 1908 and 1929. Of these fifteen, or 2.9 per cent, proved fatal as a result of the operations, and 484 were followed up. Two hundred and nine patients were given postoperative roentgen irradiation, while 175 were not so treated, fifty-nine, in whom operation could not be performed, lived on an average of seventeen months, ten surviving the three year limit and three the five year limit. Dissection of the supraclavicular fossa did not bring about better results in the advanced group. The modern radical operation calls for the removal of a large area of skin, the pectoral muscles and the axillary lymph nodes. The dissection is begun with the removal of the lymph nodes in order to eliminate the possibility of embolic transmission of carcinoma cells. It is questionable whether electrosurgery will add much. The author is impressed with the improvement in the results from the postoperative roentgen irradiation. The combination of preoperative and postoperative irradiation should give even better results. He divides his material on clinical and histologic data into the following groups: I Small tumor, no palpable lymph nodes and no carcinomatous invasion of these on histologic examination. IIa Finding of carcinomatous invasion of lymph nodes. IIb Adhesions of tumor to skin or pectoral fascia. IIc Invasion of the skin, muscles and lymph nodes. III Involvement of the supraclavicular lymph nodes. Group I gave 100 per cent of three, five and ten year cures. Groups IIa and IIb gave 69.2 per cent of three year cures, 53.2 per cent of five year cures and only 34 per cent of ten year cures. Palpable lymph nodes, regardless of histologic examination, make the prognosis unfavorable, as was seen from a decline from 100 per cent of five year cures to 53.2 per cent. Spread of tumor or of metastases through biopsy was not observed. Other clinical data influencing the prognosis were age, size, duration, type of tumor and its localization in the breast and coexistence with pregnancy. No reliable criteria for the prognosis were obtained from the histologic determination of the type of tumor. The further the spread from the primary tumor within the breast the worse the prognosis. An attempt to evaluate the prognosis on the basis of grading the maturity of the cancer cells after the method of Broders was not of much help. Hueper's method of prognosticating from a histologic malignogram, based on twenty histologic characteristics, was found to be not as reliable as the less complicated clinical evaluation supported by histologic examination and investigation of the lymph nodes.

Gastric Surgery—Peters reports the gastric operations performed in Lotheissen's clinic in Vienna from 1922 to 1932. There were 102 patients operated on for cancer of the stomach, 196 for gastric-duodenal ulcer, 170 for free perforation of a gastric or duodenal ulcer, and fourteen for uncontrollable bleeding from an ulcer. The mortality of the operation for carcinoma of the stomach amounted to 45 per cent for ulcer to

1734, for perforation 134, and for hemorrhage 428. Of the forty-seven patients who survived the operation for carcinoma forty, or 80 per cent, died within from two to three years after the operation. A follow up of 113 patients operated on for gastric-duodenal ulcer showed that seventy-six were completely cured, while thirty-seven had symptoms of indigestion as well as of new ulcers. Of those who survived the operation for perforation, from 80 to 95 per cent were free from symptoms. More careful follow up studies showed that extensive gastric resections were followed from five to ten years later by disturbances in the blood picture, the intestinal flora and the nutrition of the patients. The author mentions three cases in which a hypoblastic anemia developed after a Finsterer resection of four fifths of the stomach. The cured patients were found constantly to have a normal or a subnormal acidity, suggesting that anacidity aimed at by the advocates of extensive resection is not necessarily a favorable factor in the cure. He did not find any difference in the results among those who smoked or consumed alcohol when compared with those who did not smoke and abstained from alcohol.

Goiter Caused by Iodized Salt—After reviewing the history of the prophylactic use of iodized salt Mühe shows that in addition to statistics which report the efficacy of this measure there have also been reports about the damages caused by iodized salt. A number of cases of goiter were observed in the author's clinic, in which the use of iodized salt seemed to be a causal factor. She points out that it is proved by clinical observations on patients with syphilis and with arteriosclerosis that hypersensitivity to iodine is relatively frequent in southern Germany. Moreover, even the advocates of goiter prophylaxis by means of iodized salt realized the possibility of injurious effects and consequently laid down the following rules: 1. Iodized salt should be used only in quantities that correspond to the usual salt consumption. 2. It should be used only by persons who have a normal sympathetic nervous system. 3. Persons with cardiac defects should not use iodized salt. 4. Patients with goiter or with othercretory disturbances should abstain from the use of iodized salt. 5. Iodized salt should not be used by women during the climacteric period. The author gives the clinical histories of some of the thirty-seven patients in whom the use of iodized salt resulted in exophthalmic goiter, and she emphasizes that goiter prophylaxis by means of iodized salt should be carried out only under medical supervision.

Changes in Blood Protein Bodies in Salyrgan Diuresis—Schally investigated whether the blood proteins change during salyrgan diuresis and whether these changes are related to the diuresis. He found that following the intravenous injection of salyrgan the albumin increases and the fibrin values decrease. These changes appear regularly with the onset of the diuresis but do not develop after the intake of larger quantities of water. The author believes that the increase in the albumin content is a necessary attendant phenomenon of the mercury diuresis, in that the inflow of water into the capillaries takes place only in case of simultaneous inflow of albumin. During nephrosis there exists a blockade for protein inflow, and thus water is retained in the tissues. Consequently the replacement of the blood protein is blocked and the protein value is low in cases of nephrosis. Salyrgan prepares the capillaries for the inflow of protein and thus also for the inflow of water counteracting the protein blockade. The capillaries are permeable for protein under normal conditions, and the thesis of the semi-permeable membrane cannot be maintained since the replacement of blood protein must likewise be accomplished through the capillaries. The permeability for protein is dependent on the condition of the capillaries and is one of their vital functions.

Disorders of Cauda Equina and Their Treatment—According to Mauss and Krüger, independent inflammations of the roots of the spinal nerves have been designated as radicular neuritis or as radiculitis, and it was generally assumed that they were caused by syphilis or tuberculosis, that is, by processes which developed in the meninges or bones and from there spread to the roots. That they may be caused also by other conditions has been recognized in recent years. It appears that the caudal roots are most frequently involved, and for this reason the authors decided to study this form of radiculitis more thoroughly. They report the histories of three patients who underwent surgical treatment and they evaluate the various therapeutic measures that may be employed in chronic inflammations of the cauda equina. They reach the conclusion that there are disorders of the caudal roots, which may be caused by various infections and intoxications. Considered from the anatomic pathologic point of view, these are chronic inflammatory processes commencing in the meninges, particularly the soft meninges and the coverings of the roots, which, in their further course, may involve also the parenchyma. These meningoradiculitides appear in all forms from simple lumbar or sacral radicular neuralgia up to severe symptoms of compression. They are acute subacute or chronic in character, and depending on the anatomic development of the process from the periphery to the center, an irritative and degenerative phase can be differentiated. The majority of cases remain for a longer or shorter period in the phase of radicular irritation and present only slight sensory disturbances in addition to the radicular pain. A careful examination of the sensibility is therefore necessary if the radicular origin of the lesion is to be recognized. Occasionally the diagnosis can be supported by the detection of an increase in the protein content of the cerebrospinal fluid, even if there is no compression in the cauda equina, however, this symptom is frequently absent particularly during the later course of the disorder and, in a considerable number of cases the diagnosis must therefore rely on the detection of the segmentally localized disturbances of sensibility. The treatment consists, in addition to general and local measures, of epidural injections, eventually combined with repeated spinal punctures. Surgical treatment is indicated only in the severe forms, in which a chronic serous or fibrous meningitis exists and in which spontaneous recovery is doubtful.

Medizinische Klinik, Berlin

*Modern Therapy of Schizophrenia. G. Giehm—p. 547

*Treatment of Paroxysmal Tachycardia with Large Doses of Quinidine. S. Feher—p. 549

Meralgia Paraesthetica—Sittig and his associates report the histories of four patients with meralgia paraesthetica (Bernhardt's disease). Their observations indicate that the disturbances in the sensibility may be of various types, namely pains, paresthesias, insensibility only when touched, and hypesthesia or hypalgnesia only when the sensibility is tested without subjective disturbances. The authors point out that in their first patient the disorder developed after a laminectomy, in the second after a subcutaneous injection into the thigh, and in the third after a trauma. The fourth case is noteworthy because tests revealed that the sensitivity to pain and to cold was reduced and yet there was no subjective discomfort. The authors state that in the first patient there existed a spina bifida of the fifth lumbar vertebra and a sacral hiatus. Moreover, in the first and third patients rheumatoid or neurotic pains (sciatica) preceded the development of the symptoms of meralgia paraesthetica, and other reports record this same observation.

Therapy of Schizophrenia—Giehm points out that the etiology of schizophrenia is still a matter of dispute and that, because this factor has not been cleared up, numerous therapeutic measures have been suggested. He lists twenty different methods together with the names of those who recommended the different measures and shows that these methods can be classified in three groups: the sedative methods, the shock ther-

pies and the psychotherapeutic methods. It appears that patients with schizophrenia are subject to endocrine disturbances. Whether these endocrine disorders are the cause or the result of schizophrenia has not been established as yet, but it is evident that relations exist between schizophrenia and the glands of internal secretion. The author decided to give attention to this endocrine factor in the treatment. He combined fever therapy with hormone injections. The fever therapy was carried out by injecting a bacterial protein preparation once or twice each week. The total number of injections varied between eight and twelve. The author treated thirty patients in all. The fever therapy was followed by hormone injections. The hormone treatment was adapted to the different endocrine disturbances. The combination therapy produced encouraging results. A tabular report indicates that it was most effective in the late catatonic, the catatonic and the hebephrenic forms of schizophrenia. The restlessness and anxiety subsided gradually, sleep improved and the hallucinations disappeared. In patients with paranoid disorders and with dementia simplex, the combination fever and hormone therapy was of little avail.

Treatment of Paroxysmal Tachycardia with Quinidine—Feher reports two especially severe cases of paroxysmal tachycardia, in which the continuous oral administration of large doses of quinidine proved effective. The patients were given daily from 25 to 45 Gm. They tolerated this treatment well and the author is convinced that it is superior to the continuous treatment with intravenous injections of quinine. He considers the oral administration of large doses of quinidine indicated in prolonged and daily recurring attacks of paroxysmal tachycardia. However, the treatment is contraindicated in patients with severe circulatory insufficiency.

*Complications Caused by Meckel's Diverticulum E. Neumann —p. 655

*Indications for Parathyroidectomy R. Wanke —p. 657

Röntgenologic Aspects of Brain and Its Meminges F. Schorcher and W. Bussem —p. 663

Complications Caused by Meckel's Diverticulum—Neumann points out that Meckel's diverticulum is a persistent remnant of the omphalomesenteric duct and occurs in from 2 to 3 per cent of persons. It may lead to intestinal obstruction or acute inflammatory abdominal disturbance. Even peptic ulcers have been known to develop in Meckel's diverticulum for it may contain islands of gastric mucous membrane as well as of pancreatic tissue. The author emphasizes that in abdominal disturbances with obscure etiology the surgeon should consider the possibility of complications due to the existence of Meckel's diverticulum. If in the course of a laparotomy done on account of symptoms indicating appendicitis the appendix is found to be normal, it is necessary to inspect the lower portion of the ileum so as not to overlook a Meckel's diverticulum. Moreover, in case of umbilical anomalies and of recurring abdominal colics, Meckel's diverticulum should also be thought of. The author reports six cases in which a Meckel's diverticulum caused complications, the type differing in every case. He observed strangulation ileus, severe inflammation and kinking as in adhesion ileus, umbilical inflammation, Littre's hernia and umbilical fistula. He emphasizes that complications arising from Meckel's diverticula may develop at any age, one of his patients was 5 and another 69 years old. Some diverticula, even large ones, never cause complications.

Indications for Parathyroidectomy—Wanke points out that in recent years parathyroidectomy has been done occasionally without adequate justification in disorders in which the etiology had not been cleared up as yet. He concedes that in generalized osteodystrophia fibrosa (von Recklinghausen) in which there exists a disturbance of the calcium metabolism, parathyroidectomy has been found effective. However, he thinks that the intervention should not be carried out until after the demonstration of a pathologic increase in the calcium content of the urine and the blood serum and that the metabolism should be carefully examined in doubtful cases. In cases of abnormal calcium metabolism, resulting from a hyperfunction of the parathyroids, the intervention usually discloses a tumor-

like hyperplasia of one of the lower parathyroids. The removal of this hyperplastic parathyroid body is generally followed by a decrease in the formerly pathologically increased calcium values of blood and urine. The author describes his studies on the calcium metabolism of a patient with ankylopoietic spondylarthritis (Bechterew), in whom parathyroidectomy had been done on the basis of fluctuations in the calcium content of the blood. The postoperative tests revealed that the hypercalcemia had not been influenced by the operation. The author shows that in ankylopoietic spondylarthritis the hypercalcemia is not the manifestation of a disturbance in the calcium metabolism but probably the result of an increase in the calcium that is being transported because of a calcium atrophy of the skeleton resulting from immobilization. He points out that on the basis of histologic studies on ankylopoietic spondylarthritis the disorder is not a degenerative reaction but rather a typical arthritis with round cell infiltration, hyperemia, proliferation of the connective tissue and subsequent ossification. The chemical as well as the morphologic aspects indicate that ankylopoietic spondylarthritis is not an endocrine or a degenerative disorder, and parathyroidectomy can therefore have no therapeutic effect.

Zeitschrift für Tuberkulose, Leipzig

72: 321-456 (April) 1935

*Pneumothorax Therapy Particularly Its Renewal K. Veiel —p. 321
Peculiar Case of Pulmonary Atelectasis in Artificial Pneumothorax G. F. Bume —p. 340

Blood Picture in Tuberculosis J. Leitner —p. 343
Relation Between Physician and Patient in Public Sanatorium T. Peters —p. 378

*Tuberculosis and Endocrine System D. Epstein —p. 383

Renewal of Pneumothorax Therapy—Veiel tried the renewal of pneumothorax in fourteen cases. He succeeded in eight, but the pneumothorax was not therapeutically effective in all of them. He gained the impression that the prospects for a successful renewal are greater in patients with exudative foci (infiltrative processes) and other signs of increased sensitivity (increased temperature and deviation to the left) than in cases with a chronic productive course. The duration of the first pneumothorax and the interval between its cessation and its renewal are of no essential importance for success or failure. The development of an exudate during the first pneumothorax does not necessarily lead to development of adhesions between the pleurae. However, in case of a large exudate later development of adhesions is probable. If the first pneumothorax is maintained until the foci have largely healed, pleural adhesions are less likely than if the pneumothorax is interrupted earlier. The author describes two cases of pneumothorax in which the lung expanded considerably under an exudate and part of the exudate entered the upper portions of the pleural cavity. This condition appeared in the roentgenogram like a pleural adhesion with a superimposed exudate. However, the introduction of a small amount of air was sufficient to collapse the lung again and let the exudate slide down. The author reaches the conclusion that, if a relapse develops in a patient who has been treated with pneumothorax, an attempt should always be made to renew the pneumothorax. Only after several such attempts have failed or the renewed pneumothorax proves ineffective is there justification to resort to thoracoplasty or to other surgical interventions. No efforts should be spared to maintain the pneumothorax until the solid healing of the foci has been effected, for that is the best protection against a relapse. If a progressing lesion makes a bilateral pneumothorax necessary the older pneumothorax should not be discontinued too soon. The pneumothorax is most frequently interrupted on account of high exudates that may produce adhesions between the pleurae. In such cases it is necessary to watch for the onset of the resorption by regular roentgenoscopies and pressure controls and then to collapse the lung again either by simple refilling or if necessary, by withdrawal of a portion of the fluid and its replacement by air. Even in cases in which the roentgenogram seems to indicate the presence of adhesions, attempts should be made to renew the pneumothorax, for the exudate may only have been pressed upward and the lung may only lean against the thoracic wall and not yet adhere.

Tuberculosis and the Endocrine System—Epstein shows that a study of the relationship between tuberculosis and the endocrine system should consider three factors: 1. How do

functional anomalies in the endocrine system influence the course of the tuberculous process? 2 How does tuberculosis manifest itself in any of the endocrine glands? 3 How does the tuberculous process influence the functions of the endocrine glands without producing specific changes in them? The author first considers the thyroid and shows that tuberculosis is rare or, if present, takes a mild course in patients with hyperthyroidism. The development of tuberculous foci in the thyroid is rare, and they lack a progressive tendency when they occur. There is evidence that the thyroid is an important factor in protecting the organism against tuberculosis. The thymus likewise is rarely affected by tuberculosis and seems to play a defensive part in the organism's fight against tuberculosis. In discussing the hypophysis, the author points out that its glandular portion may be destroyed by a tuberculous process. The latter may be isolated or the manifestation of a generalized tuberculosis. Moreover, in addition to these purely tuberculous processes, tuberculotoxic changes may take place in the hypophysis. The clinical aspects of tuberculosis of the hypophysis is characterized by a deficiency of symptoms. Some authors mention the presence of comatose conditions, falling out of the hair and psychologic changes. Regarding the relation between the adrenals and tuberculosis, the author points out that insufficiency of the adrenals in the form of Addison's disease is a postprimary tuberculosis. Diabetes mellitus, the manifestation of insufficiency of the pancreas, produces a predisposition for severe forms of tuberculosis, and a tendency to caseation is most pronounced in tuberculous patients with diabetes mellitus. Moreover, tuberculosis of the pancreas is not as rare as is frequently assumed, but toxic manifestations in the pancreas in the form of a sclerosis of the organ are more frequent than tuberculous foci. Tuberculosis frequently becomes activated during the period of puberty, particularly in females. Gestation and lactation likewise seem to stimulate the tuberculous process, while during the menopause and in aged persons tuberculosis seems to take a rather mild course. Menstruation may be normal, but dysmenorrhea and amenorrhea do also occur during tuberculosis. The author mentions increased libido during tuberculosis, exacerbation of the tuberculous process with the onset of pregnancy, rare concurrence of severe phthisis and testicular tuberculosis, and retardation of the tuberculous process following castration. Some authors warn against the use of ovarian preparations in amenorrheal patients with tuberculosis.

- *Use of Urine of Pregnant Women in Form of So-Called Hormone Clysters in Treatment of Menstrual Disturbances R. Tachezy—p. 972
- *Decidua Formation in Cervical Polyps and Its Diagnostic Significance H. Willer—p. 979

Physiology of Milk Production.—Anselmino and his associates show that by means of female sex hormones it is possible to produce in the rudimentary mammary glands of castrated male rabbits the changes that are characteristic of pregnancy and that the male animals can be brought to lactation if they are treated subsequently with the lactation hormone of the anterior lobe of the hypophysis. In studying the developmental phases through which the mammary glands of these animals pass, the authors found that the follicular hormone stimulates the growth of the lactiferous ducts and that, following this preliminary treatment, the alveoli develop under the influence of the active principle of the corpus luteum in collaboration with small amounts of estrogenic substance. After the mammary glands have been completely developed under the influence of the female sex hormones (follicular hormone, active principle of corpus luteum and estrogenic substance) they respond to the lactogenic stimulation of the lactation hormone of the anterior lobe of the hypophysis and true lactation develops in the castrated male animals. The action of the lactation hormone is dependent on the developmental stage of the mammary glands, the hormone is ineffective if the alveoli are not sufficiently developed. Thus, whereas the female sex hormones produce the development of the female breast without stimulating lactation the hormone of lactation elicits lactation with-

out influencing the development of the mammary gland. The concerted action of the various hormones results in lactation.

Urine of Pregnant Women in Treatment of Menstrual Disturbances.—Tachezy employed the urine of healthy women who were in an advanced stage of pregnancy. He administered the urine in the form of enemas. In order to obtain a more rapid resorption, the so called hormone enema of 100 cc. of urine from pregnant women was preceded by a cleansing enema. The number of hormone enemas differed in the various cases. In one of the patients, fifty-two were administered in twenty six days. The author employed them in nineteen cases, especially in patients with oligomenorrhea and amenorrhea. The results were satisfactory in most cases. The treatment had a favorable effect not only on the ovarian function and menstruation but also on the entire organism. The author thinks that the favorable effect of these hormone enemas may be due to the fact that a not entirely pure hormone preparation was used. He points out that Siebert likewise expressed the opinion that an incompletely purified preparation is more effective than crystalline estrogenic substance. It is possible that accompanying substances facilitate the resorption. The method has the advantage that it permits the administration of large quantities of hormone in a form in which they are eliminated by the organism. The author concedes that the method is not esthetic but emphasizes that it is inexpensive and generally easily obtainable.

Decidua Formation in Cervical Polyps.—Willer describes the histories of four women with decidua formation in cervical polyps and the simultaneous existence of intra-uterine pregnancies and gives a tabular report of seventeen cases he found in the literature. In discussing the development of the ectopic decidua formation in cervical polyps he emphasizes the importance of inflammatory processes, on the basis of which develop changes that resemble greatly the mucous membrane connective tissue of the uterus and on which the specific hormone actions of pregnancy can exert their influence so that a decidua formation may take place. This signifies that the detection of ectopic decidua formation in a cervical polyp removed on account of hemorrhages or other manifestations may eventually be the first sign of an existing pregnancy. The author cites a case in which he thinks that a previously unrecognized pregnancy might have been preserved if instead of an immediate curettage, the results of the histologic examination of the polyp had been awaited.

Treatment of Parkinsonism.—Seletskiy and his co-workers report a method of treating chronic encephalitis (parkinsonism) by injection of the patient's own blood in the cerebrospinal canal. The method consists of first withdrawing 1 or 2 cc. of cerebrospinal fluid and replacing it by the same amount of blood taken from the vein of the patient. From three to five treatments were given at intervals of from five to seven days. The first two injections were well borne, headache, nausea, malaise or rise in temperature not being noted. The subsequent injections were not so well tolerated, and the patients complained of fatigue and loss of appetite. The treatment was administered to ten patients. The earliest improvement was noted in the gait, which became livelier, freer and more energetic. The masklike facial appearance diminished and the voice became stronger and louder. The patients became less apathetic and more sociable and communicative. In some of the patients there was a diminution of salivation, improvement in the act of mastication and to some degree diminution of the symptom of propulsion. However, the tremor of the hands and feet as well as myoclonia were not in the least benefited. The effects of the treatment are temporary, but repetition of it again produces favorable results. The authors regard the improvement in the symptoms as a nonspecific protein effect.

THE CLINICAL USE OF ANESTHETIC AGENTS AND METHODS

CHAIRMAN'S ADDRESS

JOHN S LUNDY, M D
ROCHESTER, MINN

It has been suggested that I discuss the extent to which the inexperienced person may be justified in using certain anesthetic agents, in comparison with persons who are experienced in the use of these agents.

The factor that should receive first consideration in the clinical use of an anesthetic agent is safety both at the time of administration and subsequently. It seems best to discuss each agent separately and briefly and to stress general principles that seem to me controversial only in isolated instances.

Derivatives of Barbituric Acid—In certain emergency cases any practicing physician is justified in using the barbiturates in large doses for example, in cases of tetanus, eclampsia or pregnancy, or convulsions caused by meningitis or by strychnine poisoning. A derivative of barbituric acid is most effective when given intravenously. The Council on Pharmacy and Chemistry of the American Medical Association has issued two valuable reports on the intravenous use of barbitol compounds.¹ When a barbiturate is given intravenously, the rate of injection should be slow enough so that marked depression of respiration does not occur, since individuals vary, no rule can be given other than that the respiration must be watched. Perhaps as important as the rate of injection is the initial assurance that the stomach is empty and, thereafter, maintenance of a good airway. A sterile, soluble salt should be used for intravenous administration. If only the insoluble acid is available, it can be given by mouth, in tablets or capsules, if the patient can swallow, if he cannot swallow, it can be given by rectum. The general practitioner advisedly gives the barbiturates by mouth, in small doses, as sedatives. It is now apparent that these drugs are habit forming to certain types of individuals and I feel that if the patient becomes addicted to the use of a barbiturate that patient may possibly be emotionally unstable and constitutionally inferior, with psychopathic tendencies. As preoperative or postoperative medication, these drugs are valuable and are safely used in small doses in the majority of cases. Intravenous injection of the barbiturates to produce surgical anesthesia should be confined to minor operations of short duration, and administration should

be by experienced persons. These injunctions should hold until it has been definitely shown that the drug has a wide margin of safety and that fatalities are unlikely to occur from moderate overdosage.² The latter requirement for safety, in all probability, never can be met, and so I advise against the giving of the barbiturates intravenously by those inexperienced in their administration whenever another anesthetic agent can be used instead. If, for some reason, it is the only anesthetic available, or if no other one can be used, the administrator must see to it that the patency of the airway is maintained.

Tribrom-Ethanol in Amylene Hydrate (Avertin in Amylene Hydrate)—This substance with the long names is a substitute for ether in olive oil when the rectal or colonic method of producing anesthesia is to be used. Rectal administration of any anesthetic agent is not ideal, for absorption varies with individuals. The physiologic action of tribrom-ethanol in amylene hydrate is similar to that of chloral hydrate and it may be used by the inexperienced person, provided the dose is not larger than that which will produce basal anesthesia, provided use of the drug is avoided if the patient has an extensive pulmonary disease, with cavitation, such as tuberculosis and bronchiectasis, provided it is not employed in the presence of advanced disease of the liver, pancreas, or kidneys, and provided the user follows carefully the directions for preparing the solution that accompany the drug. Preliminary medication not to exceed the average dose may be used to advantage in connection with this drug, and a patent airway must be maintained at all times. The experienced will be able to use tribrom-ethanol alcohol in amylene hydrate in larger doses and in a greater variety of cases than the inexperienced. Its use is being presented at this meeting by Drs Shipway and Wood.

Cyclopropane—Cyclopropane (C_3H_6) is the anesthetic gas most recently made available, and it has been introduced by Waters,³ wisely, in a conservative manner. The time has not yet come when it can be safely used as a routine by the inexperienced person. Even the occasional user and the experienced anesthetist will find that the agent should be administered carefully and its effect observed constantly. This is especially true when Guedel's⁴ apneic technic, or any approach to it is attempted. Although anesthesia may be induced quickly with this agent, it is not advisable to hurry the induction of anesthesia with it. The inflammability of the agent is a definite hazard. Its effect on the heart has not yet been definitely established, however, some experiments are being reported and may lead to further clinical investigation. It must be obvious, therefore,

4 Guedel A. E. Personal communication to the author.

that as yet more than usual caution should be exercised in the use of this agent. However, for either the experienced or the inexperienced person, I think that this agent would be safer from the standpoint of purity and fire hazard than acetylene, for the use of which I think there is no longer a justifiable reason in this country.

Ethylene—Ethylene (C_2H_4) may be used by the relatively inexperienced individual with relative safety if fire hazards and anoxemia are carefully avoided.

Nitrous Oxide—Nitrous oxide (N_2O) should not be used by those who are totally inexperienced. It may be employed with relative safety by the occasional user and it is used advantageously by the experienced person.

Diethyl Ether—Diethyl ether (C_2H_5)₂O is one of the safest agents that the inexperienced can use and yet produce relatively satisfactory anesthesia. It is the agent most frequently resorted to by even the experienced when surgical anesthesia with other agents is unsatisfactory. The method of its administration is simplest when the drop method is used, and for the inexperienced this method is the safest. The experienced person seldom resorts to the drop method but often adds ether to the gases. Use of anesthesia produced by oil and ether, given rectally, should be limited to the experienced anesthetist, but analgesia or basal anesthesia may be used with safety by the inexperienced, especially in anesthetization of obstetric patients.

Divinyl Ether—Divinyl ether (C_2H_3)₂O should not be used by the inexperienced person as yet. The experienced will probably use it only occasionally until it has been definitely established that it has advantages over ethyl ether. Other ethers need not be considered here because they are not readily available.

Chloroform—Chloroform ($CHCl_3$) in anesthetic doses should be administered only by one experienced in its use and by one who recognizes its dangers and contraindications. Its use as an analgesic in very small quantities is widespread and in obstetrics it seems to be generally useful and practical. One who uses this agent should be cautious not to administer it in concentrated form, that is, without admixture with sufficient air, and when possible some other agent is to be preferred.

Ethyl Chloride—Ethyl chloride (CH_3CH_2Cl) may be used with considerable safety for freezing areas that are to be incised, and its administration for local anesthesia requires almost no experience. However, as a general anesthetic agent its use should be limited to the experienced user. The occasional user may use it with relative safety in very small amounts at the beginning of induction of anesthesia, to be followed by ether. In any event, when it is used as a general anesthetic the open drop method should be employed in preference to spraying it on the mask. Only the experienced should use the closed method in administering ethyl chloride.

Regional Anesthesia—This is so valuable in the hands of those who are experienced in its use that I think the inexperienced person should be encouraged to use it in suitable cases provided he will bear in mind that one should aspirate before injecting procaine, to avoid intravenous injection, that procaine is the safest drug to use for this purpose, that procaine rarely should be injected in concentration greater than 1 per cent.⁵

unless the amount to be injected is very small as, for example, for dental block, and that the rate of injection should be relatively slow, as a further precaution against untoward reactions attributable to intravenous injection. A further protection against the convulsive effect of procaine is given by administration to the patient of small quantities of a barbiturate before the injection is made. Oral administration of a barbiturate, from thirty to forty minutes beforehand, is recommended.

Local Anesthesia—Local, or infiltration, anesthesia, with the use of dilute solutions of procaine, is the safest method and agent with which to produce anesthesia, and I think it should be used by the inexperienced as well as by those who are experienced. It should be borne in mind however that, when epinephrine is added to the solution, its proportion should be such that its dilution will be high, say 1:250,000 or even higher. Further, any one who uses a local anesthetic agent should make certain that the drug supplied is the drug desired and that it has been properly prepared and is of the proper concentration. A sharp needle should be used, and the least amount of trauma should be produced by minimizing the number of times the needle passes through the tissues.

Spinal Anesthesia—This is a method that depends for its success on the judgment of the person administering it, and it should not be used by the inexperienced. The occasional user should limit the dose to that which is considered safe and he should avoid the method if patients are markedly debilitated, that is, if recently they have lost much weight, if their hemoglobin is of very low concentration, if they have had recent severe hemorrhage, or if marked hemorrhage may occur during the operation, the method is not safe, either, in the presence of marked dehydration and inanition. In using spinal anesthesia, it is often combined with gas anesthesia, but combination of spinal anesthesia with drop ether anesthesia should be avoided if possible.

Mixtures—Mixtures of anesthetics such as alcohol, chloroform and ether, or alcohol, chloroform and ethyl chloride are, I think, as dangerous as their most dangerous constituents, and at present I think that use of mixtures should be avoided, especially by the inexperienced.

Morphine Sulphate—Morphine is injected subcutaneously with relative safety. Its use intravenously probably should be limited, but occasionally it is advantageously given intravenously, especially in the presence of very severe pain or in an emergency case when a quick effect is necessary. If ether is to be administered rectally in oil, morphine is a good drug to use in order to slow elimination of the ether from the lungs. Morphine is well omitted as preliminary medication if ether is to be given by the open drop method, not because most patients will do poorly when both are used but because, in a few cases, the combined effect will depress the respiratory center prior to the appearance of relaxation, when relaxation is important and cannot be obtained, the operation may be materially interfered with. One of the barbiturates can well replace morphine if ether is to be administered by the open drop method.

Magnesium Sulphate—The use of magnesium sulphate ($MgSO_4$) should, I think, be limited to the experienced person because, if it is given superficially rather than intramuscularly, an abscess may develop. There must be no question of its sterility and only prepara-

5. Mayer, Emil. The Toxic Effects Following the Use of Local Anesthetics. An Analysis of the Reports of Forty-Three Deaths Submitted to the Committee for the Study of Toxic Effects of Local Anesthetics of the American Medical Association and the Recommendations of the Committee. J. A. M. A. 82: 876-885 (March 15) 1924.

tions of it that are put up in ampules should be used. Its advantages are not sufficient to justify its use in the hands of an inexperienced person.

Idiosyncrasy—When a patient advises against the use of a certain drug or says that he has an idiosyncrasy to any anesthetic agent, local or general, this warning should not be ignored and, if possible, use of the drug should be avoided. In the event that it must be used, tests should be carried out, only the smallest quantity of the agent being used, to determine, if possible, whether the patient is hypersensitive to its effect. This is probably best carried out by the patch test, which is done by applying a very small amount of the agent on an applicator and holding it against the skin for a specified time, together with a control.

SUMMARY

There are three types of persons who administer anesthetics: (1) the experienced, (2) the occasional user and (3) the inexperienced. This paper is especially intended for the one who would be considered inexperienced, even though he might have informed himself by reading or by other means than the actual use of anesthetics. The inexperienced person who has attended good demonstrations of the use of a given agent is an exception. There is no better way to teach the art of anesthesia than by practical demonstrations, and I would advise those interested in anesthesia, but who are inexperienced, to take advantage of present-day opportunities to receive such teaching.

The anesthetist, whatever he sees demonstrated, whatever he knows, and whether he is experienced or inexperienced, should never forget that, of two anesthetic agents of similar toxicity, the more volatile one is the safer.

SILENT MASTOIDITIS

GEORGE D. WOLF, M.D.

NEW YORK

The diagnosis of silent mastoiditis is often difficult because of the very mild systemic as well as local manifestations of the disease.

Silent mastoiditis may be defined as an insidious progressive destruction of the mastoid process with or without otorrhea. The disease is afebrile and painless in its course. The tympanic membrane is usually involved, the hearing may be slightly or considerably impaired, and a history of some middle ear infection is frequently obtained.

Occasionally the ear condition is discovered only after the appearance of systemic or intracranial complications. In infants postauricular swelling or subperiosteal abscess may often be the first indication of mastoid involvement.

The response to timely surgical intervention is usually satisfactory, but failure to recognize the condition may lead to serious consequences.

Silent mastoiditis has been discussed in otologic literature under various and confusing names. Thus, Amberg¹ suggests dividing mastoid disease into three groups: mastoiditis acutissima, acuta and subacuta. The objection to the use of the name subacute mastoiditis for the disease discussed here is that it is a type of true mastoiditis preceded by no obvious acute phase.

"Latent mastoiditis"² and "mastoiditis without apparent involvement of the middle ear"³ are terms that have been used most freely in recent years. Hempstead³ differentiates the two. "Mastoiditis, without apparent involvement of the middle ear, should not be confused with latent suppurative otitis media. In these cases there is deafness and sometimes pain, but no spontaneous discharge of pus. The tympanic membrane is without luster, full, and sometimes markedly bulging, and paracentesis is always followed by the discharge of pus."

The descriptive phrase "primary mastoiditis"⁴ is being employed less often, and nearly all careful observers doubt whether mastoiditis, excluding the traumatic type, is ever primary.

Other terms employed to describe this condition are asymptomatic,⁵ atypical evolution,⁶ atypical,⁷ hidden,⁸ dry necrosis,⁹ hyperplastic serosa,¹⁰ idiopathic,¹¹ insidious,¹² painless,¹³ symptomless,¹⁴ unusual types,¹⁵ vacuum,¹⁶ without tympanitis,¹⁷ and the like. Most of these terms do not express the entire clinical and pathologic picture and do not hint at the main features of the disease.

For the sake of uniformity it is suggested that the term "silent mastoiditis" should be adopted, except when the classic acute mastoiditis is described with a subtitle to indicate the pathologic factor. This is particularly desirable since the term "silent" is frequently employed for similar clinical pictures, such as silent tuberculosis, silent bronchiectasis and silent gallstones.

Great progress has been made in the surgery of the temporal bone, in reducing mortality, in the duration of postoperative treatment, and in postauricular disfigurement.

Although Friesner¹⁸ recently suggested a chemical test of the aural exudate to determine bone destruction, time alone will tell whether this is satisfactory. For the present, the physician still relies on his experience and clinical judgment. When to operate is a question of debate on which internists, surgeons and otologists themselves are by no means in agreement. There are some who operate early and others who prefer to wait, even in strongly suggestive cases. In Dench's¹⁹ opinion, an ear discharge that does not clear up in two weeks justifies mastoidectomy.

Koerner²⁰ has always found bone destruction when there is a profuse ear discharge lasting from four to six weeks. He believes however that, when the discharge tends to diminish in character but lasts even longer than from four to six weeks, bone involvement may or may not be present.

Indeed, the patient with silent mastoiditis presents a most perplexing problem to the otologist. In many instances the symptoms are so slight that it is difficult to convince the patient or even the family physician that the pathologic process is in the mastoid cell.

The following case will illustrate this point.

CASE 1—B S, a man, aged 47, married, a dentist, developed a sharp pain in the right ear after surf bathing four days previously. After six hours the ear drum ruptured and the pain subsided. On examination, Aug 27, 1929, his right ear showed a small amount of pus. When this was wiped away, a small central perforation was apparent. There was no tenderness over the mastoid region, nor was there any other significant objective sign. Hearing was slightly diminished. The rectal temperature was 98.6 F. The patient was advised to have the drum incised in order to allow better drainage, but he refused to submit to myringotomy until the third week of his illness.

From then on he continued under office treatment and observation for ten weeks, throughout which time the rectal temperature varied from 98.6 to 98.8 F. There were no other outward signs or symptoms except for some diminution of hearing on the right side and some narrowing of the right ear canal. The patient continued with his professional and social duties without any interruption until October 25, almost ten weeks from the date of the onset, when he was seized with a severe right-sided hemicrania. Objectively, except for some pain on deep pressure over the antrum region, there were no significant changes.

A roentgenogram at this time showed evidence of a large cavity occupying nearly all of the lower half of the mastoid process. The blood count revealed leukocytes, 7,400, neutrophils, 80 per cent, of which 67 per cent were segmented form and 13 per cent band form, 16 per cent lymphocytes, and 4 per cent mononuclears.

He was admitted to Sydenham Hospital and October 30 a mastoidectomy was performed. At operation an empyema of the mastoid with a perisinuous abscess was found. The post-operative course was uneventful. The wound healed on the third postoperative week. The ear canal was dry and hearing returned to normal.

ETIOLOGY AND PATHOLOGY

It is generally conceded that all cases of middle ear infection are accompanied by mastoid involvement. In the great majority of cases the process in the mastoid resolves spontaneously, although a small but appreciable percentage pursues a silent course. The probable explanation for this, although necessarily conjectural, is nevertheless based on clinical experience. The virulence of the organism and the resistance of the individual play an important rôle.

Anatomic variations of the temporal bone must be regarded as important factors in influencing the course of the disease. Mithoefer²¹ thinks that a thick cortex masks the symptoms greatly. A narrow antrum will dam the secretions. In a small-celled mastoid, "the small alveoli, besides being invested with a thin epithelium, also contain a connective tissue layer in the interstices of which are present large numbers of leukocytes. The latter offer a certain amount of protective influence, which may limit the spread of the

infection for the time being and may have a tendency to establish a latent character of the disease."

The same condition might also explain the absence of reaction temperature. For the absence of pain even in cases of empyema of the mastoid process, Buck¹³ suggests that the various organisms responsible for the bone destruction may produce toxins possessing a decidedly anesthetic power over the sentient nerve fibers. He cites tuberculous ear involvement as an example.

Free pus may or may not be found. One usually encounters an abundance of granulation with bone destruction and, frequently, exposure of the dura over both the lateral sinus and the middle fossa.

Any organism may cause either silent or typical mastoiditis. *Streptococcus mucosus-capsulatus* of Schottmüller (type III pneumococcus) deserves special attention. It causes a type of otitis and mastoiditis that differs considerably from the ordinary suppurative organism. It is endowed with the ability to destroy bone quietly, and it has a marked predilection for nerve structure.

Clinically, according to Dickie,²²

the onset of mucous otitis is characterized by painlessness and absence of fever. There is some impairment of hearing, tinnitus, and a sensation of fullness in the ear. The drum head shows only trifling changes, such as slight opacity with reddening of the malleus. Frequently no perforation occurs and the condition apparently subsides, although the deafness and a sensation of fullness persist. After a period varying from one to as long as three months, symptoms of mastoiditis or intracranial complications develop. During the quiescent stage it is unusual to find mastoid tenderness, even where there is extensive caries of the underlying bone. The discharge is noticeably sticky and mucoid.

The condition in its earlier stages is almost indistinguishable from mucoid subacute middle ear catarrh, hence the latter condition must always be viewed with suspicion and kept under observation for some time.

The following case is typical.

CASE 2—H S, a married man, aged 54, a merchant, seen Jan 4, 1933, had had a head cold six weeks before, followed a week later by pain in the left ear. Four days later the ear drum was incised by his local physician with temporary relief. About one week later the pain in the ear returned and the drum was re-incised. The ear discharge gradually decreased, but a severe buzzing in the left ear and mild headaches persisted.

On examination the patient appeared to be well nourished, but his tongue was thickly coated. The left ear canal was filled with a thin mucopurulent discharge, there was a small perforation in the lower external quadrant, and the fundus was narrowed. There was decided evidence of periostitis in the region of the left mastoid. He could hear neither the whispered nor the spoken voice with his left ear, while tuning fork tests showed loss of hearing for both high and low tones. The Weber lateralization was not conclusive. The rectal temperature was 99.6 F.

These changes suggested the clinical diagnosis of mastoiditis due to *Streptococcus mucosus-capsulatus*, and immediate operation was advised. At the hospital, urinalysis and complete blood examination were essentially negative. However, the roentgen examination showed the left mastoid hazy, the trabeculae absorbed, and interseptal markings coalesced. At operation the following day the superficial layers of the mastoid cells were found to be necrotic and filled with granulations. The deeper layers and the aditus ad antrum were filled with pus. A simple mastoidectomy was performed. While culture from the canal revealed *Streptococcus haemolyticus*, that from the mastoid showed *Streptococcus mucosus-capsulatus*. The post-

operative course was uneventful. After four weeks the mastoid wound was completely closed, the ear dry, and the perforation healed. Hearing returned to normal, but the tinnitus, though diminished, was still annoying.

DIAGNOSTIC CRITERIA

Of necessity, diagnostic criteria must be presented with reservations. Although no single sign or symptom is conclusive in the diagnosis of silent mastoiditis, a correlation of all evidence presented will lead, in most cases, to a correct conclusion.

1 *History*—A careful history of the onset of all symptoms, no matter how slight, their clinical course and their present status is of prime importance. The type of treatment and its effects on the subjective or objective changes should be considered.

2 *Discharge*—The absence of aural discharge is rare. When otorrhea exists, the duration and nature of the discharge should be noted. Bone involvement must be strongly suspected if, in spite of intelligent treatment over a period of three weeks, the discharge has not abated or ceased, so that the patient states that his pillow is considerably stained with pus after he has lain on the diseased side. The type of discharge is most important. A thin discharge is generally due to an involvement of the mucous membrane of the middle ear, whereas a thick, fetid discharge usually signifies bone necrosis.

3 *Hearing*—Repeated examinations of the hearing on the affected side are sometimes helpful. Progressive loss of hearing indicates bone or auditory nerve involvement. Unfortunately, good hearing does not exclude the possibility of extensive bone destruction or serious intracranial complications.

4 *Objective Manifestations*—Pasty appearance, thickly coated tongue and loss of weight may be in evidence. The drum head usually shows definite changes, such as narrowing of the external auditory meatus near its fundus with apparent shortening of the meatus. Deep mastoid tenderness and edema over the mastoid area late in the disease (Griesinger's sign), no matter how slight, are further indicative.

5 *Headaches*—Headaches must be carefully watched for. No other symptom merits more consideration on the part of the attending physician. One should not wait until the patient complains of headaches but should make constant, though diplomatic, inquiry to discover this symptom. Headache is probably nature's first signal of some meningeal irritation before the meninges are actively invaded.

6 Nausea and vomiting are of significance.

7 Sleeplessness and restlessness at night are often valuable clues, especially in children, in cases in which other information is either unobtainable or unreliable.

8 *Transillumination*—The use of the Mosher transilluminator is advocated by Bacon,²³ and Shambaugh is very enthusiastic about this diagnostic aid. In a drawn out case of silent mastoiditis, in which repeated radiographic examinations are not practicable, this method might be of value.

9 *Laboratory Aids*—A great deal has been written on this phase of the subject, and the literature reflects the lack of adequate evaluation of the various laboratory procedures as diagnostic aids. These can be grouped as (1) bacteriologic, (2) hematologic and (3) radiologic.

Bacteriologic Bacteriologic studies are of some diagnostic and prognostic aid. Only smears obtained from the ear canal at the time of or very shortly after the paracentesis or spontaneous rupture are of value. Later on the infection becomes a mixed one.

The presence of either the hemolytic or the non-hemolytic streptococcus does not necessarily indicate serious involvement, since most of these cases, in spite of their stormy onset, subside very quickly. However, the presence of an encapsulated streptococcus should put the physician on his guard immediately. Absence of the capsule does not, per se, absolutely exclude this organism, because of its known ability to lose the capsule in certain culture mediums.

In suggestive cases the tubercle bacillus should be searched for, and guinea-pig injections may be necessary. Mycotic infection of the ear canal is not uncommon. In rare instances Vincent's organism is at the bottom of the trouble and should be looked for. The diphtheria bacillus in ear infections has been reported on a number of occasions.

Hematologic It is essential to bear in mind that the lesions confined to the cellular bone structure do not show as high leukocytosis or relative polynucleosis as when the soft parts are involved. Hence a high blood count does not necessarily indicate mastoid disease, nor does a low one exclude it. In this connection the Schilling count may be helpful. The main practical feature of the Schilling count is the recognition of the nonsegmented (band) neutrophil cell, which normally constitutes from 4 to 8 per cent of all leukocytes. According to Eisenberg and Nemens.²⁴

If the infection is progressing, the most dependable hematologic sign is the increase in percentage of the band cells regardless of whether the total leukocyte (W. B. C.) count and the total neutrophil count rise. If the two latter counts are also high, it is ever so much more favorable than when they are low. This would point to the exhaustion of the hematopoietic activity of the bone marrow. In other words, the steady rise of the band cell points to an invasive, progressive nature of the infection, pus formation and, if postoperative, to unfavorable termination.

3 **Radiologic** In every case in which mastoid involvement is suspected, a roentgenogram should be made. The following should be looked for: (1) direct evidence of bone destruction, (2) regional anatomy—whether the mastoid is pneumatic, diploic, sclerotic, large, small or mixed cell type, and the position of the lateral sinuses. Not only is this information of assistance in interpreting the clinical behavior but it is also of definite value at the time of the operation.

It is necessary to emphasize here that particular attention should be paid to the radiologic technic, careful angulation and proper exposure being employed since failure to do so may give misleading results. It is also necessary to bear in mind that a previous infection in the same ear may confuse the picture and must be differentiated from the current pathologic changes.

DIFFERENTIAL DIAGNOSIS

In the differential diagnosis of silent mastoiditis the following conditions, according to Turner,²⁵ must be excluded.

1 **Tuberculosis** of the middle ear, which has a painless onset. The discharge is watery in the beginning and later becomes flocculent. It may also become

offensive and purulent The lymph glands surrounding the ear are enlarged Multiple perforations of the tympanic membrane are pathognomonic Facial paralysis develops in 45 per cent of the cases

2 Syphilis, which is characterized by a rapid onset of deafness, and the labyrinth is often affected Tinnitus is marked and giddiness may be present Pain is very slight

3 Malignant conditions Carcinoma in adults and sarcoma in children are very rarely encountered Here discharge is copious and fetid The granulations are exuberant, bleed easily, and recur readily after removal

PROGNOSIS

The large number of chronic cases of discharging ears of many years' standing which do not respond to local conservative treatment are instances of an old, overlooked silent mastoiditis Besides being annoyed with constant or remittant otorrhea, the patient finds his hearing becoming more and more impaired on the involved side, and frequently an increased severity of symptoms may necessitate a radical mastoidectomy, with total loss of hearing as a postoperative result

The following case is an example of a silent mastoiditis on one side and a flareup on the other side in a patient who had had a silent mastoiditis twenty-five years previously The patient also suffered from chronic lymphatic leukemia and diabetes

CASE 3—S H, a man, aged 68, married seen in the office, April 17, 1929, had had a pain in the right ear, following a mild infection of the upper respiratory tract four weeks before, which discharged spontaneously forty-eight hours later with abatement of the local pain There followed a profuse aural discharge, for which he had been under the care of a local physician. A week before the examination he had been suffering from a severe hemiparesis, with an impairment of hearing on the affected side There was a history of diabetes mellitus of long duration About twenty-five years before, after a mild acute otitis media, his left ear drum had ruptured spontaneously There had been a remittent aural discharge, which, except for the deafness on that side, had given little trouble.

On examination, both ears were found to be filled with thick pus There was a large central perforation in the left ear drum, with pus under pressure coming out constantly The left tympanic membrane was practically destroyed There was no local tenderness or edema in either mastoid region and no Romberg sign, spontaneous nystagmus, ataxia, or past pointing He could hear only loudly spoken voices The rectal temperature was 98.6 F Hospitalization was advised for immediate treatment of what seemed to be right silent mastoiditis

The patient was admitted to Sydenham Hospital the same day Urine examination revealed sugar, 27 per cent, acetone, present, blood sugar, 250 mg per hundred cubic centimeters, blood count hemoglobin, 79 per cent, red blood cells, 4,064,000, white blood cells, 9,600, polymorphonuclear leukocytes, 18 per cent, of which 12 per cent were band forms, large lymphocytes, 78 per cent, mononuclears, 2 per cent, lymphoblasts, 4 per cent, and many basket-shaped cells At a subsequent blood examination the large lymphocytes increased to 92 per cent

After the administration of sufficient insulin to control the excess of blood sugar, the patient was operated on the following day The right mastoid was filled with thick pus There was enormous destruction of bone, with epidural and perisinuous abscesses Culture from the mastoid showed *Streptococcus nonhaemolyticus* The postoperative course was uneventful, and the patient left the hospital on the tenth day in the care of his local physician He was again seen, May 6 The right mastoid wound was almost completely healed, the ear was dry, and the perforation was closed. He complained, however, that shortly after reaching home he had discovered that his left ear had flared up with profuse discharge and

almost constant pain. There had been an extremely severe left hemiparesis for the past five days, which also kept him awake at night

Exacerbation of the left chronic mastoiditis was evident, and he was operated on the next day Although a radical mastoidectomy was indicated, a simple one was performed at this time because of the patient's debilitated condition On this occasion as well, the postoperative course was uneventful, and he returned home two weeks later When examined three months later, both mastoid wounds were healed, the ears were dry, and the left tympanic membrane even showed a tendency toward regeneration Hearing in both ears improved considerably but did not return to normal

It is safe to say that, in many instances in which a patient is advised to submit to an operation and apparently recovers without it, there is no proof that the advice was wrong While in some cases the recovery may be permanent, not infrequently recurrences requiring operative intervention take place sooner or later In discussing this point, Braun² says

Where the symptoms of an acute mastoiditis have subsided under conservative treatment and after several weeks or months of good health the symptoms recur, we are not dealing with a second attack of mastoiditis in the majority of cases We will usually find that the disease has been progressing continually since the first attack, and these cases always show extensive bone involvement with (not commonly) some intracranial complications

The following experience confirms this opinion

CASE 4—M W, a girl, aged 9½ years, admitted to Sydenham Hospital March 3, 1933, had suffered an attack of acute otitis media two years previously At that time the ear drum drained for one week Since then there had been a thin discharge from that ear at regular intervals During the early part of January 1933 she had a recurrent acute attack of right otitis media, and the drum ruptured spontaneously This time the discharge persisted For one week before admission she complained of severe pain in the right supra-orbital region, which was accompanied by projectile vomiting No speech, mental, gait or psychic disturbances were noted She had no convulsions or other neurologic manifestations

On examination the ear showed slight mastoid tenderness without edema The ear drum had a large central perforation with a thin discharge exuding She had, however, well marked meningeal signs, which were described by Dr Wechsler, neurologist, as follows "Child alert and cooperative, apparently in no pain Mild neck rigidity, bilateral Kernig, hyperactive reflexes, with ankle and patellar clonus, bilateral Babinski, good abdominal reflexes, corneal reflexes present. No palsies, no ataxia, no sensory disturbances, no ocular, facial, palatal or tongue palsies, slight horizontal and vertical nystagmus, particularly to right side, somewhat to left. There is a slight blurring of the right disk margin. There are no signs of cerebellar or temporal lobe abscesses"

Urinalysis revealed from 5 to 15 white blood cells per low power field Examination of the blood showed hemoglobin, 75 per cent, red blood cells, 4,990,000, white blood cells, 9,050, subsequently increased to 31,900, segmented forms, 44 per cent, band forms, 16 per cent, small lymphocytes, 34 per cent, large lymphocytes, 6 per cent. Spinal fluid was under increased pressure and showed 650 polymorphonuclear leukocytes per cubic millimeter Cultures of the blood, spinal fluid and smear from the mastoid at operation were positive for *Streptococcus brevis*

An epidural abscess was found at operation, with old granulations and necrotic mastoid cells The dura was covered with granulations and seemed under pressure.

In spite of the obliteration of the lateral sinus, the ligation of the jugular vein, repeated forced spinal drainages, and administration of antistreptococcus serum and whole blood transfusions, the child died on the twenty-fourth day after admission

It seems fair to assume that the present pathologic process was a continuation of the process initiated two years previously and that this life might possibly have been saved by an early mastoidectomy.

However, such instances are not uncommon. Otolgic literature is replete with many cases of brain abscesses, general sepsis, and other complications following silent mastoiditis.

COMMENT

It is not the intention to convey in this paper the impression that every case of ear infection that does not clear up quickly is necessarily surgical. Watchful waiting is often the best procedure. It is necessary, however, to realize that the mildness of the symptoms is not indicative of the extent of the involvement of the mastoid process. When the case becomes protracted, vigilance on the part of the attending physician is of importance. Unless the ear becomes perfectly dry, the perforation of the drum healed and its luster regained within a reasonable length of time, the physician must not give the patient a false sense of security, even if pain and fever are absent. It is certainly unwise to allow a patient who is otherwise well to go on to the stage of chronicity until all means, including surgical, have been exhausted. Even if meningeal and other complications are comparatively rare, the patient is often doomed to a steady or intermittent otorrhea with marked impairment of hearing. In many instances, timely surgery will prevent these distressing sequelae.

SUMMARY AND CONCLUSIONS

1 Attention is again called to a clinical type of mastoiditis, perhaps best characterized as silent mastoiditis because of the lack of frank clinical manifestations in the presence of a progressive pathologic process.

2 This condition is important because it is relatively common, frequently produces serious auditory damage and not uncommonly causes death through intracranial or systemic complications.

3 Mastoidectomy is the rational, conservative and effective treatment for this condition. This operation in competent hands is always safe and is practically without mortality. It should therefore be preferred to chronic invalidism and possible dangerous complications.

4 Headaches during the course of ear infection should be regarded as an early warning against procrastination of adequate surgical therapy.

5 The cases that have been presented illustrate the clinical features of silent mastoiditis, the diagnostic problems it may present, and the therapeutic procedures required to obtain satisfactory results.

INJURIES TO MUSCLES AND TENDONS

KEENE O. HALDEMAN, M.D.

AND

RALPH SOTO-HALL, M.D.

SAN FRANCISCO

The accuracy of diagnosis that one associates with fractures is lacking when the injury involves muscles and tendons. The overlapping of the latter structures and their supplementary actions make for confusion in diagnosis, often render treatment illogical and prolong convalescence. It is only by a careful segregation of the distinct clinical entities that real progress can be made. In order to review the clinical picture of these injuries we have analyzed a series of 100 injuries to muscles and tendons, which represents a cross section of private, industrial and clinic practice. We have omitted the injuries to soft parts which resulted from lacerated wounds or compound fractures.

In a consideration of the injuries of muscles and tendons, one should employ a classification such as the following, which seems to us logical because it is based on the causative forces, the contributing factors and the relative frequency.

- 1 Direct trauma
 - A blow or crushing force applied to a muscle.
- 2 Indirect trauma
 - (a) A stretching force applied to a contracting muscle or its tendon.
 - (b) A sudden or unusually forceful contraction of a muscle.
- 3 Spontaneous rupture
 - (a) Post-traumatic
 - I A single injury which so weakens a muscle or tendon that rupture occurs at a later date.
 - II Often-repeated minor injuries, for example, the rupture of the extensor pollicis longus tendon following a Colles fracture.
 - (b) Disease of the tendon or muscle: tuberculosis, gonorrhea, syphilis or typhoid.
 - (c) Semility, a factor that is often combined with one of the foregoing conditions.
- 4 Dislocation of tendons.
- 5 Herniation of a muscle through its sheath.

Statistics regarding the muscles or tendons involved, the most comprehensive of which are given by Grassheim¹ (500 cases), list the following ruptures in the order of their frequency. Muscles of the calf, extensors of the leg, biceps, achilles tendon and extensor of the thumb. In recent years certain other muscles have been found to be the site of frequent ruptures, namely, supraspinatus, triceps, rectus abdominis, adductors of the thigh and extensors of the fingers. From the well executed experiments of McMaster,² on the breaking weight and site of rupture of a preparation of muscle and tendon, it is concluded that the normal tendon does not rupture but that rupture occurs at one of the following sites: the attachment of tendon to bone, the musculotendinous junction, or through the muscle substance. Before we present our statistical observations, certain distinct clinical entities should be described.

Anatomy and Physiology of the Psyche—The outstanding goal of our efforts as I see them today and as they are represented by the psychoanalytic school is to build up slowly and painstakingly an anatomy and a physiology of the psyche comparable in exactness of its outlines and complexity of its structures to the anatomy and physiology of the body. If our thinking is moving along in the right direction we much believe that bodily and mental states are not either separate or different from one another but are only two aspects of the organism—as a whole, from either one of which we may view its activities. If this is so as I have reiterated so many times then the history of the psyche reaches as far into the past as that of the soma and for each state of one there is a corresponding repercussion in the other.—White W. A. Psychiatry as a Medical Specialty, Thomas W. Salmon Memorial Lecture, read before the New York Academy of Medicine, April 12, 1935.

TEAR OF THE SUPRASPINATUS TENDON

Injuries to muscles that have attachment to the shoulder girdle offer some of the most perplexing problems in diagnosis. The frequency and importance of partial or complete tears of the supraspinatus tendon have been recognized only since the work of Codman.³ However, we feel that Codman confused certain anatomic changes in the shoulder that are the result of senile wear and tear with purely traumatic lesions. Meyer⁴ described the attritional changes of the shoulder, and one of us (R. S.-H.) had the opportunity to inspect a large series of his dissections of the shoulder. These shoulders present longitudinal fibrillations or fraying of the supraspinatus tendon, and even perforation into the joint. However, these perforations have round, smooth edges suggesting prolonged wear and tear. Degenerative processes are visible also on the surface of the acromion. Clinically, the fact that supraspinatus tears are rather infrequent has been strongly impressed on us,

Fig 1—Frontal section of the shoulder region to show the point of insertion of the needle for the purpose of anesthetizing the subdeltoid bursa as a diagnostic and therapeutic procedure

following the injection of procaine hydrochloride into the subdeltoid bursa as a differential diagnostic method.⁵ We believe certain acutely painful shoulders, with traumatic onset and complete loss of abduction, are the result of reflex inhibition of the supraspinatus muscle.

The supraspinatus tendon forms the roof of the shoulder joint and the floor of the subacromial or subdeltoid bursa. Conditions involving these two structures must be differentiated from tears of the supraspinatus tendon, for which purpose we have followed a routine method of examination.

1 The history in cases of injury to the supraspinatus tendon is usually that of a fall on the shoulder or on

the outstretched arm, which is followed by an immediate and complete loss of the power to initiate abduction. The gradual onset of limitation of abduction suggests an arthritis or bursitis.

2 On physical examination one observes an atrophy of the supraspinatus muscle, the extent of which depends on the period of time that has elapsed since injury. On attempting to raise the arm, the patient often leans to the affected side to permit the weight of the arm to initiate abduction. Once the arm is partially abducted, the deltoid muscle can act to complete this movement. There may be a point of tenderness over the roof of the shoulder joint just beyond the tip of the acromion, if the supraspinatus tendon is torn.

3 The roentgenogram of the shoulder with a light exposure may demonstrate or rule out calcification of the subdeltoid bursa, arthritis or fracture in the region of the shoulder. In tears of the supraspinatus tendon, the head of the humerus may be found in a higher position than normal in relation to the glenoid fossa.

4 In acute cases we have made it a practice to inject from 10 to 15 cc of 1 per cent procaine hydrochloride into the subdeltoid bursa (fig 1). The needle is directed toward the upper border of the greater tuberosity of the humerus. As soon as the bone is struck, the needle is withdrawn one-eighth inch and an attempt is made to aspirate any fluid that may be present in the bursa, then the procaine is injected, followed by a small amount of air. In those cases in which there is a reflex inhibition of function of the supraspinatus muscle as a result of subdeltoid bursitis or adhesions, the patient is able to abduct his arm actively a few minutes after this injection of procaine. Under the local anesthesia so produced it is possible to carry out stretching movements of the shoulder joint that have a valuable therapeutic effect. A similar benefit was observed from the injection of procaine into calcified subdeltoid bursae. These often show a disappearance of the calcium deposits within a few days, and the patient's subjective symptoms also disappear. In such cases no other type of treatment is required, although we sometimes repeat the injection. If no improvement in the active abduction of the shoulder results from this injection, the diagnosis of tear of the supraspinatus tendon is made certain.

5 In chronic cases in which an injury to the supraspinatus tendon is suspected, the problem is largely that of ruling out the effect of periarticular adhesions, which limit both passive and active abduction of the shoulder. We have found it possible to stretch many of these adhesions by the application of double skin traction for from five to seven days. The patient lies in a semi-Fowler position, with from 6 to 8 pounds of traction applied along the axis of the humerus with the shoulder abducted as much as possible. At the same time, the elbow being flexed at 90 degrees, about 5 pounds of traction is applied to the forearm so as to rotate the shoulder externally. The amount of abduction and external rotation of the shoulder so obtained is increased gradually, during which time the relaxation of the muscles is favored by the use of an electric pad. In many of these cases the stretching and breaking of adhesions restores the function of the shoulder and rules out the question of injury to the supraspinatus muscle.

When a diagnosis of tear of the supraspinatus tendon has been made, the treatment will depend on the completeness of the tear. The use of an abduction splint

3 Codman E. A. On Stiff and Painful Shoulders. Boston M. & S. J. 15:4: 613-620, 1906. The Shoulder. Rupture of the Supraspinatus Tendon and Other Lesions in or About the Subacromial Bursa. Boston: Thomas Todd Company, 1934.

for from four to six weeks followed by physical therapy, will suffice in cases of partial tear. A complete tear should be repaired surgically as soon as its diagnosis is made, because much harm will result from delay. A short incision, made by splitting the anterior fibers of the deltoid muscle, will give sufficient exposure of the roof of the shoulder joint to permit the diagnosis of tear of the supraspinatus tendon to be confirmed. The superior end of this incision is then extended back and over the acromion (the saber cut incision) and this structure is severed at its base and turned down with the deltoid muscle, to expose the supraspinatus tendon. The ruptured tendon may be reinserted in a groove in the tuberosity of the humerus and the acromial process fixed in place with a beef bone peg. The shoulder must be immobilized in abduction for three or four weeks after operation.

RUPTURE OF THE LONG HEAD OF THE BICEPS

The subject of rupture of the long head of the biceps was to have been introduced by stating "The attention of the profession has been recently directed to the rupture and dislocation of the long head of the biceps" until it was found that these exact words were written by Robert Storks⁶ in 1843. A further perusal of the literature revealed a description by J. G. Smith,⁷ just 100 years ago, of the shoulders of five cadavers which presented tears of the tendons of the supraspinatus, infraspinatus, subscapularis and long head of the biceps in various combinations. This author also observed the medial dislocation of the latter tendon out of the bicipital groove and described graphically the arthritic changes that were associated with ruptures of the tendons around the shoulder joint. Picard⁸ in 1838 described a rupture of the biceps tendon at the commencement of its groove, in the autopsy of a patient who had presented a nutlike swelling of the biceps muscle during life.

Of the many other authors who have written on this subject during the past century, mention should be made of Morton,⁹ who in 1886 was the first to describe the operative repair of a ruptured biceps tendon, and of Ledderhose,¹⁰ who reviewed the literature thoroughly up to 1909 and advanced the thesis that degenerative changes must be present in a biceps tendon prior to its rupture. Of recent articles, the most comprehensive have been written by Ghetti,¹¹ who presented seven cases and reviewed the European literature, by Gilcreest,¹² who made a painstaking analysis of 100 cases of injury to the biceps muscle, and by Meyer,⁴ who described fifty-nine dissections of shoulders showing a rupture or dislocation of the long head of the biceps.

Tears of the biceps tendon become more frequent with advancing years because of the fraying out of the tendon where it is subjected to constant friction in the bicipital groove and over the head of the humerus. The actual rupture usually results from a sudden forceful contraction of the biceps muscle against a counterforce

The presence of such an injury becomes apparent when the patient flexes his elbow against resistance. If the long head is ruptured, the belly of the biceps muscle will assume a spherical shape as the result of an abnormal depression at its superior lateral border, which is in striking contrast to the oval contour of the normal contracting biceps. (Five of our patients are shown in figure 2, in all of whom the diagnosis was later confirmed by operation.) This injury results in marked weakness of the flexor muscles of the elbow and is frequently accompanied by pain over the anterior aspect

Fig. 2—Preoperative appearance of five patients in whom the diagnosis of rupture of the long head of the biceps muscle was later confirmed by exploration. A depression is visible in the contour of the injured muscle near its upper pole.

of the shoulder joint or over the bicipital groove. Patients for whom no repair is done lose some of the power of abduction, owing to the formation of peri-articular adhesions.

In recent years, an interesting diagnostic problem arises. The hematoma produced by a tear in the upper part of the tendon gravitates downward through the sheath to the region of the belly, where it presents. The ecchymosis and tenderness suggest that the tear took place at the musculotendinous junction. This occurred in two cases in which we exposed the belly of the biceps muscle and then had to carry the incision upward to find the tear in the bicipital groove.

It is extremely important for the return of function that such an injury be diagnosed early and that an adequate repair of the torn tendon be carried out. We usually operate for this condition under local anesthesia, with the patient sitting erect in a chair. The conscious cooperation of the patient is of great value in all operations for the repair of muscles and tendons. When the site of rupture has been exposed by an incision along the anterior border of the deltoid muscle, the type of reconstructive operation chosen will depend on the condition of the tendon and the site of rupture. If the tendon is separated from its glenoid origin, we attach it to the coracoid process along with the short head. A rupture at the musculotendinous junction may be repaired with braided silk. Rarely it has been necessary to shorten the tendon of the long head by a reefing procedure or to pass it through a hole drilled in the head of the humerus.

DISLOCATION (SLIPPING) OF THE BICEPS TENDON

Occasionally the long head of the biceps shows a tendency to slip medially out of the bicipital groove when the humerus is rotated externally, with the biceps contracting and the shoulder in abduction. In the dissecting room, Meyer⁴ observed this condition to be present in thirty-nine subjects. A clinical presentation of this injury was made by Abbott¹³ in 1934.

Clinically, the diagnosis is made on the occurrence of a snap, which is felt and heard over the bicipital groove and which may be painful. In patients presenting a permanent dislocation of the tendon out of the bicipital groove, the usual complaints are those of weakness of the arm and localized tenderness. There is some resemblance between the clinical pictures presented by the slipping of the biceps tendon and the crepitations found in subdeltoid bursitis. The latter diagnosis is confirmed if one is able to relieve the symptoms and cause a disappearance of the snap by the injection of procaine hydrochloride into the subdeltoid bursa, which procedure, as one patient recently put it, "seems to oil the joint."

The treatment of permanent or recurrent dislocation of the biceps tendon is operative. The presence of adhesions in the bicipital groove usually renders impossible the restoration of the normal gliding mechanism, for which reason the best results have been obtained by the insertion of the tendon of the long head through a hole drilled in the head of the humerus, or by the attachment of this tendon to that of the short head.

STRAIN OF THE RHOMBOIDEUS MUSCLES

Strain of the rhomboideus major or minor muscles is seen rather frequently in an industrial practice and is usually caused by a sudden, incoordinated movement of the shoulder. These muscles arise from the ligamentum nuchae and the spinous processes of the seventh cervical to the fifth thoracic vertebrae. They insert along the vertebral border of the scapula, which is drawn upward by their contraction.

Physical examination following this injury shows a localized tenderness between the midthoracic spine and the scapula, with the production of pain at this point when the shoulder is carried passively into extreme forward flexion or is extended actively against resistance. Treatment requires the partial immobilization of the scapula,

which is best accomplished by drawing it backward and upward with adhesive strapping. A similar result is obtained by winding a wide strip of elastic webbing around the upper part of the chest. When the acute signs of injury have disappeared it is well to apply baking or diathermy and light massage to the injured muscle. Strains of other muscles arising from the spinous processes and inserting on the scapula or the humerus (the trapezius or latissimus dorsi muscles) give a similar clinical picture and respond to the same treatment.

LATE RUPTURE OF THE EXTENSOR POLLICIS LONGUS FOLLOWING COLLES' FRACTURE

In our series we have one such case, a condition which, according to McMaster,¹⁴ has been reported twenty-seven times in the literature. The causative relation of this rupture to the Colles fracture is of importance industrially because an interval of from one to three months may elapse before its appearance. Such an injury shows the effect of chronic trauma, which leads to degenerative changes and the ultimate rupture of the tendon. Two factors that affect the gliding mechanism are partial tears in the tendon and irregularity of the bone over which the tendon moves.

RUPTURE OF THE EXTENSOR TENDONS OF THE FINGERS

Among ruptures of the tendons of the fingers, detachment of the extensor tendon at its insertion (the so-called baseball finger) is one of the commonest and most troublesome injuries. The characteristic deformity can often be avoided by immediate hyperextension of the terminal joint for at least six weeks. Thoroughness in this conservative treatment is important because later operative repair is often unsuccessful.

RUPTURE OF THE RECTUS ABDOMINIS MUSCLE

An injury that may be mistaken for some intra-peritoneal disease, such as appendicitis, is the rupture of the rectus abdominis muscle. This may occur during pregnancy or labor, or following typhoid that results in Zenker's degeneration of the muscle fibers. The rupture may result from a severe attack of coughing or sneezing. Such an accident usually tears a few branches of the epigastric vessels, causing a large hematoma to form within the aponeurotic sheath. Treatment may require the evacuation of this sheath surgically.

RUPTURE OF THE QUADRICEPS MUSCLE OR TENDON

Rupture of the quadriceps muscle or tendon occurs rather frequently, ranking second in the number of cases both in our series and in that of Grassheim.¹ The rupture may occur either at the point of attachment of the tendon to the patella or at the musculotendinous junction, with occasional cases through the purely muscular or tendinous portions. A direct blow is the usual cause, the patient often falling on the flexed knee. This injury occurs about as often in the young as in the aged. The diagnosis is suggested by the inability of the patient to extend the knee actively and is confirmed by the observation of a hiatus in the substance of the muscle or tendon. A lateral roentgen examination may be of value in demonstrating the gap in the muscle. The superior border of the patella is usually seen to tilt anteriorly. Many cases of partial tear of the

¹³ Abbott L. C. Saunders, J. C. de C. M. and Smith D. W. Traumatic Dislocation of the Tendon of the Long Head of the Biceps Brachii, presented before the sixty-third annual session of the California Medical Association in May 1934 (unpublished).

¹⁴ McMaster P. E. Late Ruptures of Extensor and Flexor Pollicis Longus Tendons Following Colles' Fracture. *J. Bone & Joint Surg.* 14: 93-101 (Jan.) 1932.

quadriceps muscle may escape diagnosis and leave a depression in the substance of the muscle, without any permanent disability. Treatment in cases of complete rupture of the quadriceps muscle or tendon should be an early operative repair with the use of sutures of fascia lata or braided silk. Cases of partial tear heal readily if the leg is splinted in full extension for three or four weeks, followed by a period of gradual mobilization.

PARTIAL RUPTURE OF A MUSCLE OF THE CALF

"Tennis leg" is the term usually applied to a partial rupture of one of the muscles of the calf. The plantaris muscle is most often affected, although one of the bellies of the gastrocnemius may be similarly involved. The patient describes a sudden burning pain in the calf during strong contraction of its muscles and may hear or feel something snap. Pain often extends up the middle of the calf to the popliteal space and is increased by passive dorsiflexion of the ankle. Treatment should consist of the immobilization of the ankle in plantar flexion with adhesive strapping for two or three weeks, after which baking, massage and active exercise are used.

RUPTURE OF THE ACHILLES TENDON

Injury to the achilles tendon occurs most often as a result of violent exercise, as performed by sprinters, boxers and mountain climbers. The site of rupture is commonly at the junction of muscle and tendon. Incomplete rupture is shown by tenderness and ecchymosis over a depression in the achilles tendon. Such cases require immobilization in plantar flexion by a cast or adhesive strapping.

The complete tears of the achilles tendon are evidenced by a marked depression caused by the separation of its fibers, and an inability to flex the foot in the plantar direction actively against resistance. Treatment,

sheath. This defect, which measured 6 by 3 cm., was repaired with strips of fascia lata, the pain on walking disappeared and the contour of the leg became normal.

A true herniation of muscle is characterized by a bulging of the relaxed muscle through a defect in its sheath and the disappearance of this bulge when the muscle contracts. On the contrary, as has been pointed

out by Ledderhose,¹⁰ the increased prominence of the belly of the biceps muscle, which is associated with a rupture of its long head, is most noticeable when this muscle is contracted.

SUMMARY AND CONCLUSIONS

Certain features are common to most ruptures of muscles. The history of a sudden sharp pain or snapping sensation, which occurs during violent muscular effort and is followed by the inability to perform certain definite movements, is very suggestive. The appearance of a defect in the belly of the muscle or in the tendon and the subsequent development of ecchymosis makes the diagnosis more certain.

Among diagnostic aids, if the lesion is not accessible, should be mentioned the lightly exposed roentgenogram which shows the soft tissues, electrical stimulation and the local injection of procaine hydrochloride. The former often shows a defect in the shadow cast by the muscle and may reveal a small chip of bone attached to a tendon that has been torn from its insertion. The faradic current, when applied to a muscle, causes it to contract, with the production of pain at the site of a tear in the muscle or its tendon. The use of procaine to test muscular function, with pain eliminated, should not be overlooked in solving those cases presenting a difficult differential diagnosis.

From our statistical study it appears that in the upper extremity the supraspinatus muscle or tendon is the most likely to be torn, while in the lower extremity the quadriceps is most vulnerable (table 1). Senility appears to play a more important role in the former than in the latter condition. In view of the prevailing belief that a degenerative process is a prerequisite of the rupture of a muscle or tendon, it was interesting to find

in this type should be operative, with the repair of the tendon either with braided silk or with a suture of fascia lata.

HERNIATION OF A MUSCLE

A rare condition which is seldom described, and one case of which we have treated surgically, is the herniation of a muscle through its sheath. In our case this injury resulted from a direct blow to the anterior tibial muscle, which occurred when the patient's leg was hanging over the side of a truck and was struck by a passing automobile. The patient was disabled and continued to have pain on walking at the site of a bulge of the anterior tibial muscle through a defect in its

that the average age of the patients in our series was 42 years, which corresponds to that period in which the greatest activity is associated with the onset of degenerative changes (fig 3). In our series of 100 patients, eighty-three were males, which fact can be attributed to the predominance of men in those branches of industry which require violent muscular effort and entail the risk of falls and other injuries.

The rôle of acute trauma seems to be much greater than all other causes of injury to muscles, including age, disease and chronic trauma. The most common mechanism producing injury to a muscle or tendon was the sudden application of a stretching force to a muscle that was contracting strongly (table 2). Spontaneous rupture was relatively rare. The treatment must be shaped to fit each situation, depending on the site, nature and severity of the injury. In general, a complete rupture should have an early operative repair, whereas in a case of partial tear immobilization may be sufficient.

REVERSED COLLES FRACTURE WITH SPECIAL REFERENCE TO THERAPY

GEORGE WEBB M.D.
AND
WILLIAM SHEINFELD M.D.
BROOKLYN

The extraordinary increase in bodily injuries within the past few years warrants frequent reviews of the knowledge of trauma therapy, to bring about a more accurate evaluation of all available information and its wider dissemination. Fractures about joints occupy an exceptionally important place in such a review. Because of the prehensile functions of the hand, fractures about the wrist have rightfully attracted a great deal of attention, thought and therapeutic endeavor. The importance of the typical Colles-Pouteau or Dupuytren fracture has been stressed by numerous authors recently, as well as in former years, but very little can be found in medical writings about the reverse Colles fracture or the so-called Smith fracture. It is true that this type of fracture, the characteristics of which will be elucidated later, is not frequently encountered. Nevertheless the surgeon should be familiar with the nature of this lesion, as it must be reckoned with from time to time.

The available literature at present is scanty, and though the etiology and pathology have been thoroughly discussed, no remarks about therapy can be found with the exception of the following statement: "Reduction should be performed under anesthesia similar to the type of reduction utilized in Colles fracture, except that the force is applied in the reverse direction."

The reverse Colles fracture is a flexion fracture and is most frequently the result of a fall on the dorsum of the hand while the hand is in flexion, causing displacement of the distal fragment anteriorly. The line of fracture through the radius is usually oblique, forming a distal triangular fragment with its base on the anterior surface of the radius and its apex on the dorsal surface of the bone. Occasionally the line of fracture will be transverse or almost so, forming a more or less square distal fragment. The characteristic feature of the fracture is, of course, the anterior displacement of the distal fragment, creating a deformity aptly described by Roberts as a "gardener's spade" hand.

With this fracture there may be associated injuries to the adjacent bones, such as fractures of the ulnar, styloid, navicular or lunate bones. The clinical manifestations are at times difficult to interpret and a reverse Colles or Smith fracture may be confused with a forward dislocation of the carpus (exceedingly rare), dislocation of separate carpal bones and Madelung's disease. Edema of the soft tissue frequently obscures the landmarks so that only roentgenograms will finally clinch the diagnosis. Functionally, motion is greatly impaired at the wrist joint, extension suffers considerably more than flexion, which is exaggerated. The present-day recorded concepts on the matter are based on reports of Smith, Callender and Roberts.

In 1854 Robert William Smith¹ in his textbook devoted a page to the description and discussion of a case. The patient had fallen on the back of the hand many months before. After the fall, a deformity had occurred at the wrist. This was characterized by a dorsal tumor, by the distal projection of the end of the proximal radial fragment and by a palmar swelling formed by the lower radial fragment. No remarks were made as to treatment.

In 1865 George W. Callender² reported several cases. The first was of a woman, aged 51, with a four weeks old fracture of the right radius. Typical deformity was present, flexion was exaggerated, but extension of the hand was limited. The second case was that of a man who had fallen on the flexed hand. Typical deformity was present. Attempts at reduction were unsuccessful. Callender says "No crepitus could be detected, nor could I in any way reduce or lessen the deformity." Ten months later the deformity was still present. Two museum specimens showing this fracture are also presented.

Following this, the next publication was that of John B. Roberts³ in 1897. Twenty-four cases were presented in that paper. Our analysis of the cases revealed that only three were from the author's own experience. They were all old cases, and no reduction was obtained

Fig. 1 (authors case)—A, before reduction; B, following open reduction; C, anteroposterior view following reduction.

in any of them. Nine cases were culled from the literature, but the sources were not mentioned nor the cases described. The other twelve cases were collected by correspondence with contemporary surgeons. Again, details as to cure or adequate reduction were withheld.

Roberts was able to find thirty-one museum specimens demonstrating the fracture, showing that the lesion was by no means a great rarity. In eleven of his twenty-four cases it was definitely established that the injury had

³ Roberts, J. B. *Am. J. M. Sc.* 113:10, 1897.

been sustained on the back of the hand. The typical clinical changes and deformity were described.

In 1905 appeared a second article by Dr. Roberts.⁴ The type of deformity was again described and the name of "gardener's spade" hand attached to it. The author considered closed reduction to be the treatment of choice.

In 1902 Bennet⁵ recognized and described a case of reversed Colles fracture, which likewise did not yield to closed methods of reduction.

Fig 2 (Dr. Gaston's case)—A before reduction, B following closed reduction, C, one week after reduction—recurrence of displacement, D anteroposterior view of wrist at discharge, one week after closed reduction.

It must be emphasized at this juncture that not one successfully reduced fracture of this type had as yet been reported at the time of Roberts' article in 1905. At the present time, the prevailing opinions as to the manner of injury, as given in the various textbooks on fractures, are not dissimilar from views expressed by Roberts. These statements occur in Key and Conwall,⁶ Scudder,⁷ Wilson and Cochrane,⁷ Lewis Stimson,⁸ Kellogg Speed,⁹ and Cotton.¹⁰ These various textbooks note the uncommonness of the lesion and suggest reduction by manipulation under anesthesia.

The following case report is one of an anteriorly displaced distal radial fragment treated in the Third Surgical Service of the Coney Island Hospital.

A R., a boy, aged 15 years, while playing football, fell backward, striking his wrist. Immediate pain and disability about the wrist were noted and the patient was brought to the hospital. Physical examination on admission revealed diffuse swelling about the wrist. The distal end of the radius was tender.

Roentgen examination on admission revealed a complete oblique fracture of the distal and anterior aspect of the lower end of the radius, with the distal fragment and radial epiphysis displaced anteriorly (fig 1A). Closed reduction, under anesthesia, was attempted but could not be accomplished in spite of expenditure of considerable force and manipulation. The roentgenographic appearance was unchanged after the closed reduction. The following day open operation was resorted to, the impacted fragments were pried apart by a chisel and reduction was then accomplished. Maintenance of the reduced fragment was obtained by use of a light plaster cast (fig 1B).

Two other cases of this type of fracture were encountered in our service at the Coney Island Hospital. Neither one of these could be reduced by closed methods, so open operation had to be resorted to.¹¹ Dr.

J. M. Morehead permitted us to include a case in which he operated at the Post-Graduate Hospital, New York, several years ago, in which the typical changes, both roentgenologic and clinical, were evident and in which attempted closed reduction was likewise unsuccessful. Here, operative reduction was also employed with excellent result.

With the permission of Dr. J. H. Gaston of the Reconstruction Hospital, New York, we are able to present illustrations of another typical case of Smith fracture (fig 2) reduced by him by closed manipulation. Six days later, however, recurrence of the displacement and deformity were noted by Dr. Gaston and operative intervention was contemplated. Dr. Gaston stated in a personal interview that, in a second similar case of his, closed reduction was likewise unsuccessful.

In view of the absence of authentic reports wherein closed reduction was accomplished and maintained and of our personal experience with this type of fracture, we feel that the reverse Colles fracture is in the majority of instances an irreducible fracture if only closed manipulation is attempted and that for some unaccountable reason it will yield only to open intervention. We feel, however, that closed manipulation should always be attempted first but that failure to succeed by this method is to be expected. We realize that the number of cases involved is too small to make any real statistical deduction.

Nevertheless, because of the uncommonness of this injury, one must needs deal with a small number of cases. It is very suggestive that in virtually all the cases cited in the early literature not one reduction was accomplished. This represents six reported cases: one of Smith's, two of Callender's and three of Roberts'. It is equally important that in our three cases and the three cases courteously communicated to us by Drs. Morehead and Gaston, not one could be successfully reduced without open operation.

Fig 3—Location of incision.

The technic of the operation is simple (fig 3). The incision is placed on the radial aspect of the wrist immediately proximal to the distal wrist fold, extending about 6 cm up the radial shaft. The superficial fascia is split the whole length of the incision. The veins of the plexus about the wrist are ligated, the tendons being retracted either anteriorly or posteriorly. The fracture line lies exposed in the depth of the wound. An osteotome is inserted between the fragments, and the impaction, if one is present, is broken up. The hand is then forcibly extended, the osteotome being used as an inclined plane on which the distal fragment slides. To facilitate this sliding motion, the osteotome

¹¹ The histories and roentgenograms of these two cases were filed under Colles fractures and the authors were unable to locate them for detailed presentation.

is rotated in an arc corresponding to the motion of the reduction. Because of the pronounced tendency to recurrence of the deformity, overcorrection of the reduction is desirable. With the wrist held in hyperextension, the fascia and skin are sutured in layers and a light circular cast extending up to the metacarpophalangeal joints is applied. From ten to fourteen days later this cast may be split, the posterior shell being removed for massage and baking. Active motion of the joint should be begun about the eighteenth to the twentieth day. The type of immobilization following operative reduction should be carefully considered. We have found the cock-up position in a light plaster cast to be the best so far.

As in all injuries in close proximity to joints, immobilization over a long period of time is undesirable. Physical therapy and motion should be begun early. In this connection it is important to realize, however, that the reversed Colles or Smith fracture has a marked tendency to recurrence, and active manipulation of the injured member should be undertaken with great care.

SUMMARY

- 1 The reversed Colles fracture is not uncommon.
- 2 No cases of successful reduction of the described fracture, by the closed method, have been reported in the literature.
- 3 The fracture is therefore considered irreducible and operative reduction is advisable.

1616 Beverly Road

TAR CANCER OF THE LIP IN FISHERMEN

PHILIP SHAMBAUGH, M.D.
BOSTON

The problem of tar cancer in fishermen was brought to my attention by an interesting case observed in the surgical wards of the Peter Bent Brigham Hospital. A brief summary of this case follows:

R. C., a healthy-appearing laborer, aged 41, admitted in September 1932, had a moderately painful swelling of the right side of the neck which had been present for six months. This was at first taken to represent tuberculous lymphadenitis, and the patient was treated for a month in the outdoor department.

Fig 1—The needle used by fishermen in repairing nets

with the ultraviolet lamp. Since there was no improvement he was sent into the hospital, where a mass of hard adherent tissue was removed, which proved microscopically to be epidermoid carcinoma involving the lymph nodes and invading the submaxillary gland. The primary source of the growth, however, was obscure, since there was no discernible lesion about the mouth. Finally the chance observation of a very tiny puckered scar on the right side of the lower lip, which had been overlooked on previous examinations, led to the following interesting story:

From the Cancer Commission of Harvard University and the Surgical Service of the Peter Bent Brigham Hospital

The patient had been employed as a fisherman for a period of six years up to three years before his admission. During this period he had used tarred nets exclusively, and in mending these nets he had been in the habit of holding the tar-smearing wooden needle between his lips on the right side of his mouth. Thus during each fishing voyage there would be, for several weeks at a time, a smudge of tar on the lips at this point. At the point of this irritation there developed a small, hard, nontender growth on the lower lip which, he was told by his

Fig 2—Tar warts on both hands of a net loft worker aged 56 who had been handling tarred nets for forty years

mates, was a "fisherman's sore." On the advice of his captain he placed himself in the care of a cancer charlatan. The lesion was treated with salves for about two weeks, when it disappeared and did not return. He had smoked a pipe but was very certain that he always held it on the left side of the mouth.

The patient was given a course of roentgen therapy to the neck, but a recurrence soon appeared and he died five months later with an esophageal fistula.

On the basis of this story an investigation was made into the industrial hazard involved in this use of tar by fishermen.

FREQUENCY OF SKIN CANCER IN FISHERMEN

Statistical studies have clearly demonstrated that fishermen are prone to develop skin cancers.¹ This high occupational incidence has been generally attributed to exposure to the sun, and but scant consideration has been given to the possibility that contact with tar might be a contributing factor.

In this country there are no statistical sources through which the incidence of skin cancer among fishermen can be accurately determined. In the course of this investigation, however, a large number of fishermen were interviewed in the various centers of the Massachusetts fishing industry—Boston, Gloucester, New Bedford and Provincetown—and in this way certain definite impressions were gained. Cancer of the lip was found to be common, and it was an interesting fact that almost all these cases, after the diagnosis had been made by local physicians, had been treated by the same woman who had treated my original patient, R. C., three years before he came under my observation. This cancer charlatan was known to most of the older fishermen from Gloucester to New Bedford, and her treatment by salves was considered by them to be

¹ Young, M. and Russell W. T. An Investigation into the Statistics of Cancer in Different Trades and Professions, London H. M. Stationery Office, 1926. Haagensen, C. C. Occupational Neoplastic Disease. *Am J Cancer* 15: 641 (April) 1931. Hoffman, F. L. The Cancer Death Rate in Selected Occupations. *American Academy of Medicine* 1915.

more efficacious than the radium or surgery advised by the physicians

This charlatan was visited in the course of the investigation. She proved to be an elderly woman who seemed to have a very accurate idea of the gross pathology of cancer of the lip. She stated that she had treated several hundred fishermen for this condition during the past twenty-five or thirty years.

EXPOSURE OF FISHERMEN TO TAR

Tar is employed extensively in the fishing industry, being used on the nets to prevent rotting. It becomes smeared on the hands and arms of the fishermen, particularly in hot weather when the tar is soft, and it is then carried by the hands to the face. Moreover, it is a common practice to hold the large wooden shuttle-like "needle" (fig 1) in the mouth while the nets are being mended. The needle soon becomes smeared with the tar, which is thus carried onto the lips.

The men who are most constantly exposed to tar are those who work in the "net lofts," where the nets are repaired and retarred. Two of these establishments were visited in Gloucester, each employing three or four men. It was found that the older workers who had been exposed to the tar for many years showed typical tar warts on the hands and forearms (figs 2 and 3). None had cancer, but they recalled that three of their predecessors, who had been engaged in the business for similarly long periods, had suffered from skin cancers. One was said to have had several cancers involving the cheek and lower lip, all successfully treated with radium. The other two died from cancer

of the lip. All of these had been accustomed to hold the needle in the mouth while mending the nets, and it was definitely known that at least one of these had never used tobacco in any form.

It is well known that the carcinogenic properties of the various kinds of tar varies widely, wood tar is apparently innocuous, whereas coal tar has been widely incriminated. Of the various types of coal tar the most highly carcinogenic is that which is produced as a by-product in the destructive distillation of coal to form coal gas. This distillation is car-

ried out in either the horizontal retort or in the vertical type of retort. The tar produced in the old fashioned and relatively inefficient horizontal types comes off at a much higher temperature and contains more carcinogenic agents than that produced in the vertical type.²

Although pine tar is used to some extent on fishing

nets, by far the bulk of the tarred nets are treated with coal tar. An investigation into the source of this tar revealed that it is obtained from local gas works that employ the horizontal type of retort. Thus it is seen that the tar to which the fishermen in the Massachusetts area are exposed is the most potent carcinogenic variety known.

Fig 4 (case 2)—A fisherman aged 77 who developed an epidermoid carcinoma on the lip at the site where he habitually held the needle in repairing tarred nets. (He was a pipe smoker but always held the pipe in the right side of his mouth.)

Fig 3—Tar wart on the forearm of a net loft worker aged 75 who had been handling tarred nets for sixty years.

It is interesting that the fishermen themselves appreciate the difference between the coal tar and the pine tar. The latter they recognize as healing and frequently apply it to their minor abrasions or hemorrhoids. On the other hand, they complain bitterly of the coal tar, which is especially troublesome in hot weather, when it causes an intense burning of the skin. It also causes an irritative condition on the forearms which they call "pingmits", evidently a pustular folliculitis, similar to the condition described by Schamberg³ as occurring commonly among workers in a tar paper plant.

TAR CANCER IN FISHERMEN

In spite of this exposure to carcinogenic tar there is but little mention in the literature of the occurrence of tar cancer in fishermen. Young and Russell¹ mention a relatively high incidence of cancer of the ear in fishermen and suggest that this might be due to tar. Bridge and Henry⁴ in 1928 reported two cases of tar cancer attributed to net fixing, and since then four additional cases have been reported to the British Factory Department.⁵ The lesions in these six cases were situated on the scrotum (two cases), forearm, hand, ear and neck. It would appear rather surprising that none of these cases were lip cancer, since the habits of net repairers

³ Schamberg J F. Cancer in Tar Workers, *J Cutan Dis* 28: 644 1910.

⁴ Bridge J C and Henry S A. Industrial Cancers. Report of the International Conference on Cancer, London 1928 p 258.

⁵ Henry S A. Personal communication to the author.

must be more or less the same in England as in this country. A possible explanation is that when cancer of the lip has occurred in net fixers it has been attributed to causes other than tar, with the result that these cases have not found their way into the aforementioned statistics.

In an effort to determine the etiologic importance of tar in cancer of the lip a study was made of the cases of cancer of the lip treated at the Collis P Huntington Memorial Hospital, Boston, during the years 1932 and 1933. One hundred and forty-one cases were investigated by questionnaire. There were seventy-nine replies, and in this number there were four who had been employed as fishermen. All four of these men had used tarred nets, and one volunteered the information that he had always held the needle in the same side of his mouth on which the sore appeared (fig 4). This man had never used tobacco, while the remaining three were pipe smokers. However, in two of these the lesion had developed on the side of the mouth opposite from the site of holding the pipe.

sure to tar was probably the important factor in these particular cases, especially so in view of the practice of holding the tar smeared needle in the mouth.

The causative role of pipe smoking, in spite of its generally accepted importance, has not been definitely established. Although pipe smoking is common in patients suffering from lip cancer, there is little evidence that it is more common than in the general male populace of a similar age group. Moreover, the few available reports that include statistics as to the site of holding the pipe do not show an increased tendency for cancer to develop at this site.⁶ This point was particularly investigated in our analysis of the cases of lip cancer treated at the Collis P Huntington Memorial Hospital in 1932 and 1933. There were seventy-nine replies to the questionnaire. Of these, sixty patients or 76 per cent, had been pipe smokers. However, of these sixty pipe smokers, the lesion had developed on the same side as the site of holding the pipe in only thirty-four, or 56 per cent. In the eight cases of tar cancer of the lip here reported, two used no tobacco at

The cases of cancer of the lip in which tar seemed to have played an etiologic role are given in the accompanying table. In addition to these eight cases there were others indirectly brought to my attention, including the two cases, previously mentioned, of fatal cancer of the lip in net loft workers.

COMMENT

Although it is felt that exposure to tar may be a factor in the high incidence of cancer of the lip in fishermen, it is certainly not the only factor involved. The outdoor life and exposure to the sun is probably a more important cause, and in addition the etiologic role of pipe smoking must of course be considered.

A statistical analysis of 750 deaths from lip cancer in England and Wales from 1911 to 1913 showed a death rate of 79.8 per million years of life among agricultural laborers and 55.0 per million among farmers as compared to only 21.2 per million among all occupied and retired males.⁶ Fishermen are probably even more exposed to the irritating action of sun and wind than are farmers. They almost universally complain of the susceptibility of the lower lip to sunburn and some wear an overhanging moustache for its shading effect on the lower lip. The fact, however, that cancer of the lip was found to occur in many net loft workers who remain largely indoors and several of whom were not pipe smokers would indicate that expo-

sure to tar was probably the important factor in these particular cases, especially so in view of the practice of holding the tar smeared needle in the mouth.

One might expect that fishermen would develop tar cancer on the arms and hands more frequently than on the lip, since the former are necessarily more constantly exposed to the tar. Although tar warts of the hands and arms were observed in several net loft workers, only one case of cancer of the arm was brought to my attention, and the impression was gained that this must be rare. This high incidence of lip cancer is, however, in accord with the observations of those who have investigated tar and pitch cancer in other industries⁷ and is probably due to the relatively high vulnerability of the lip to cancerous changes. Moreover, in fishermen there is the added factor of direct contamination of the lip by the tarred needle which is not present in the industries investigated by other writers.

SUMMARY

1 Fishermen in the Massachusetts region are exposed, in the handling and repairing of tarred nets, to the most strongly carcinogenic type of tar, namely, horizontal retort gas-works tar.

2 The lips are especially apt to be contaminated with the tar owing to the frequent practice of holding the tar-smeared needle in the mouth while repairing the nets.

3 In eight cases of cancer of the lip in fishermen here reported it is believed that such an exposure to tar was an important causative factor

4 These observations suggest that exposure to tar may be partially responsible for the apparent high incidence of cancer of the lip in fishermen

THE TREATMENT OF MALARIA WITH SMALL AMOUNTS OF QUININE

ROLLA B. HILL, MD

AND

JOSÉ OLAVARRÍA

NEW YORK

From time immemorial the physician has been inclined to prescribe, and the patient to take, quinine only so long as fever continues. Since the organization of malaria campaigns, the malariologist has been concerned over the frequency of relapse—not always distinguished from reinfection—and has tended to combine the treatment of the acute attack with the prevention of relapse. He has therefore encouraged longer and longer treatments, hoping thereby to obtain a radical cure.

This tendency culminated, in the United States, in the "standard treatment," developed by Bass and recommended by the National Malaria Committee, in which intensive treatment was given for two months. Bass¹ stated that most patients will relapse after treatment of a week or less but that 100 per cent of cases would be cured with daily treatment for three or four months.

Recent researches, however, especially in therapeutic malaria, are giving new light on the natural history of the disease and are changing the conceptions of treatment. The Malaria Committee of the Health Section of the League of Nations² gives the usual course of an infection as follows: The cure of the primary attack by quinine treatment is followed by a period of two months in which one or more recrudescences may occur. Then comes a period of from seven to ten months of probable freedom from fever, followed by a probable reappearance of fever and parasites, but with complete recovery in a year. To distinguish between subsequent attacks of fever, James³ has recommended the following nomenclature:

Recrudescence Return of fever within eight weeks after subsidence of initial attack.

Relapse Fever between the eighth and twenty-fourth weeks

Recurrence Fever after the twenty-fourth week.

This separation is useful for malariologists, but to avoid confusion the word "relapse" should be retained as a general term, and another used for the special meaning that James gives it. We would suggest the term "recidivation" for the return of fever between the eighth and the twenty-fourth week after the initial attack.

The studies on which this report is based were made under the auspices and with the aid of the International Health Division of the Rockefeller Foundation.

3 James, S. P. Some General Results of a Study of Induced Malaria in England. Tr. Roy. Soc. Trop. Med. & Hyg. 24: 478-525 (March) 1931.

Sinton,⁴ whose work on treatment is fundamental, reports that in 251 probably fresh (new) infections, treated with varying doses of drugs from one week to six weeks, the recrudescence rate was 24 per cent, while in 667 chronic cases treated from ten to fifty-six days with from 16 to 56 Gm of quinine, or of quinine plus alkali, there were recrudescences in 68 per cent. Sinton says "the evidence is very strong that the former [fresh] infections are more easily cured than the latter [chronic] infections."

Fletcher⁵ found that the average number of days of quinine treatment necessary to control the fever was 3.5 in quartan, 4.8 in benign tertian, and 4.7 in malignant tertian infections, but to cause the disappearance of parasites from the peripheral circulation 8.7 days of treatment was necessary in quartan, 4.5 in benign tertian, and 6.6 days in malignant tertian malaria.

James³ was able to infect patients with one strain of *Plasmodium vivax* after another strain had failed to produce infection. Swellengrebel,⁶ whose fifteen Dutch volunteers all had relapses after treatment with 1 Gm of quinine plus 0.03 Gm of plasmodium daily for fourteen days, used the Madagascar strain of *Plasmodium vivax* commonly employed by James. He contrasts these results with those of Piebenga, who successfully prevented relapse in sixty-seven persons who had contracted malaria naturally in Holland (local strain of *Plasmodium vivax*) and were given the same treatment.

Lowe⁷ observed sixteen persons with untreated benign tertian malaria who probably had acquired a certain amount of immunity from previous attacks years before; he found that eleven had spontaneous arrest in an average period of six days. Among twenty-nine other patients treated with 1.65 Gm of cinchona febrifuge daily for a week, there were no relapses in six months. In twenty-one *Plasmodium falciparum* infections it was necessary to give quinine within forty-eight hours to control the attack.

On the other hand, Caccini in 1902 found that all except one of 120 *Plasmodium vivax* untreated infections relapsed. Of 145 *Plasmodium vivax* infections treated early and systematically, a relapse occurred in 37 per cent. By systematic treatment Caccini meant giving from 1.5 to 2 Gm of quinine on alternate days for seven days. In 102 patients treated daily for a week with from 1.5 to 2 Gm of quinine daily, relapse occurred in 15 per cent. Some of Caccini's patients were observed for as long as nine months. Evidently the strains of *Plasmodium vivax* observed by Caccini and James and Swellengrebel were more virulent than those of Piebenga and of Lowe.

It would seem, therefore, that in the treatment of malaria one should take into account the species of parasite, the virulence of the local strain, whether infection is recent or chronic, and the amount of immunity that the patient may have acquired. A treatment that is adequate in one region may not be so in another.

7 Lowe, J. Indian M. Gaz. 69: 16-23 (Jan) 1934. abstr. Trop. Dis. Bull. 31: 420, 1934.

Nocht has stated that "quinine therapy is never a 'therapia magna sterilisans'." The work of James, and of Boyd,⁸ Lowe and others, has shown that in some cases spontaneous regression of symptoms will take place even without treatment. Other cases will yield to a very small amount of quinine, while others, as Sinton has shown, will relapse later no matter what method of treatment is followed. Yorke⁹ also states that the amount and duration of treatment have no influence on whether or not a relapse will occur. In the experience of Nicol,¹⁰ no known method of quinine treatment is effective in preventing relapses in induced malaria. It seems logical, therefore, to concentrate on the cure of the acute attack and later treat the recrudescences, recidivations and recurrence if and when they occur.

Collins¹¹ treated two groups of patients with a long (Seiffert) and a short method (1 Gm daily for three or four days). Aside from the difficulties inherent in supervising a treatment lasting for seventy-seven days, he found but little advantage in the long treatment. While the number of recrudescences was less after the long treatment than after the short treatment, it appears that the number of recurrences the following year was greater among those who had received the long treatment. Patients receiving the short treatment tended to remain free from subsequent attacks longer than those given prolonged treatment.

Rogers¹² holds that the vast majority of malarial cases will yield within from five to seven days to oral quinine in 2 Gm daily doses. Sinton¹³ recommends 2 Gm of quinine daily for seven days, which he says will cure 70 per cent of fresh infections, without regard to the species of parasite. He considers that 1.3 Gm a day is usually adequate when *Plasmodium vivax* is the common species.

The present tendency, thus, is toward shorter treatments. The Malaria Committee of the Health Section of the League of Nations² recommends as a minimal treatment in benign tertian malaria 1 Gm of quinine hydrochloride daily for five days. The opinion of the committee is that larger doses over longer periods are not more efficacious than shorter courses of treatment.

On the basis of the observations that we are reporting here, we have become convinced that with the strains of *Plasmodium vivax* with which we are dealing locally and in the absence of a large percentage of *Plasmodium falciparum* infections, a small amount of quinine is practically as efficacious as a long course of treatment. The saving of quinine is of course very considerable, and administration is greatly simplified.

MATERIAL AND METHODS

In 1931 a malaria station was established in Campo Lugar, Spain, to test the value of an antilarval campaign under local conditions. A malaria dispensary was opened to ascertain the amount of malaria occurring. To interfere as little as possible with the natural malaria transmission, and at the same time attract

patients to the laboratory, we wished only to control the acute attack. It was decided to give, as an adult dose, 1 Gm of quinine sulphate daily for four days, a total of 4 Gm. While the dispensary operated during 1931, no antilarval measures were begun until 1932.

In analyzing our cases at the end of the first year, we found that most of the recrudescences had occurred in the spring recurring cases. Only about 15 per cent of the new infections recrudescenced. The experience of the two subsequent years has confirmed our first year's observation.

Campo Lugar is a town of 1,200 inhabitants, with a stable population. The patients on whom we are reporting are all residents of the town and are known to us personally. We have thus been able to follow our cases carefully, and we believe that our statistics are as reliable as they can be under field conditions.

In 1931 about 15 per cent of the total population had new infections, this percentage being reduced to 7 in 1932 and to 2 in 1933. It is unlikely, therefore, that there were many cases of reinfection during any one year or that many of what we have called recrudescences were really new infections. There is, however, the possibility of reinfection, since the town was not entirely free from malaria. However, any error is on the conservative side, since the classification of a case as a relapse instead of a new infection makes the test of treatment more severe.

Schedule of Treatment

Age	Daily Dose in Grams
0-1	0.10 tannate in chocolate tablets
1-2	0.20 tannate in chocolate tablets
3-4	0.30 0.40 sulphate candy coated pills
5-8	0.50 0.60 sulphate in tablets
9 and up	0.75 1 sulphate, in tablets

Since this has always been a region of endemic malaria, a certain number of the inhabitants had also had previous attacks of malaria. We have no way of estimating this percentage, but there must have been some degree of acquired immunity.

The finding of parasites in the peripheral blood by the thick film method was the sole criterion for the diagnosis of malaria. For such patients the accompanying schedule of treatment was used, both in original and in subsequent attacks.

The duration of treatment was uniformly four days. The entire dose was given to the patient to be taken on his own responsibility. We believe that the total amount was usually taken. If it was not, our results are better than we report. Succeeding examinations for recrudescences and relapses were made at irregular intervals until 1933, when all cases were followed throughout the season on a regular schedule. If a recrudescence occurred, the routine treatment was repeated.

RECRUDESCENCES OF OLD AND NEW INFECTIONS

In 1931 there were eighty-six *Plasmodium vivax* infections, seen before June 1, in persons with a history of malaria in 1930, hence these infections were almost certainly recurrences from the previous year. Fifty of the infected persons, or 59 per cent, had more than one attack (recrudescence) during the year. After July 1 there were at least 137 *Plasmodium vivax* and thirty-seven *Plasmodium falciparum* infections, which

¹² Rogers L. International Conference of Health Problems Boston United Fruit Company 1924 p. 101.

¹³ Sinton (references 4 b and 4 c).

were probably new infections. Of the benign tertian cases, twenty-four, or 17 per cent, recrudesced. Of the thirty-seven malignant tertian cases, thirty-three recrudesced after our treatment.

Of the 201 cases seen in 1932, 112 *Plasmodium vivax* cases were probably recurrences of previous infections. Sixty-six of these (again 59 per cent) recrudesced after treatment. Only six of the seventy-three new *Plasmodium vivax* infections, or 9 per cent, recrudesced. There were sixteen *Plasmodium falciparum* infections in 1932, of which three were possibly old infections. Thirteen of these sixteen cases recrudesced.

In 1933, of thirty-three persons with *Plasmodium vivax* infections recurring from 1932, twenty-four, or 73 per cent, had repeated attacks. We had twenty-four new *Plasmodium vivax* infections, of which five, or 21 per cent, had showed recrudescences. There were only three *Plasmodium falciparum* cases, all new infections. All three recrudesced after treatment.

For the three years combined we therefore have the following figures:

Of 234 new *Plasmodium vivax* infections, thirty-five, or 15 per cent, recrudesced following treatment. But of fifty-three new *Plasmodium falciparum* cases, forty-six, or 90 per cent, recrudesced following the same treatment.

Of 231 persons with old *Plasmodium vivax* infections (recurrences from the previous year), 140, or 60 per cent, presented multiple attacks or recrudescences following treatment. The initial attack of the year, or recurrence, takes place in the spring, and the succeeding recrudescences begin within from two weeks to a month but may be continued for two months or more.

The fresh *Plasmodium vivax* infections, therefore, have but little tendency to recrudescence following a short course of quinine treatment, but of those which recur the following spring approximately 60 per cent will be multiple attacks in spite of treatment. This is no doubt a provision for the perpetuation of the species and explains the appearance of new *Plasmodium vivax* infections in June, with the peak in the latter part of July.

RECURRENCES OF INFECTION THE FOLLOWING YEAR

Of the 137 new *Plasmodium vivax* infections in 1931, at least fifty recurred in 1932, of the seventy-three new *Plasmodium vivax* infections in 1932, at least nineteen recurred in 1933, and eleven of the twenty-four fresh *Plasmodium vivax* infections of 1933 recurred in 1934, giving a total of at least eighty recurrences in a total of 234, or a minimum of 34 per cent of recurrences the following year. We have eliminated all doubtful cases, so that the actual percentage of recurrences is probably higher.

In fifty-six *Plasmodium falciparum* infections, however, only three presented possible recurrences the following year. These cases, as already noted, had practically all recrudesced the same year and had received additional treatment. Canara has noted similar results with a combination of quinine and acetarsone.

DURATION OF INFECTION

We have already seen that, of the 137 persons with new *Plasmodium vivax* infections in 1931, fifty experienced a recurrence in 1932. Nine of these, or 7 per

cent of the original number, again exhibited fever and parasites in the spring of 1933. Similarly there were seventy-three new infections in 1932, of which nineteen recurred in 1933, and four again recurred in the spring of 1934, a percentage of 6.

Furthermore, two other persons, newly infected in September 1932, and examined on more than one occasion in 1933 with negative results, had recurrences early in April 1934.

In all these cases there is of course the possibility of a reinfection in the second year, but a careful study of each case leads us to believe that they are examples of persistence of infection for more than twelve months.

HEMIC AND CLINICAL RELAPSES

In 1933 we followed our cases intensively from the time of the first attack until the end of October, in an attempt to study the relation between parasites in the peripheral circulation and clinical recrudescences. The schedule called for three examinations four days apart, beginning one week after the end of the initial attack, then weekly for the remainder of the month, and monthly thereafter, unless clinical symptoms supervened, in which event an examination was made at once. We divided the recrudescences into two types: (1) clinical, when parasites were found and the patient had fever, and (2) hemic, when there were parasites but no clinical symptoms.

Of the sixty persons found with positive reactions during the year, fifty-eight returned for subsequent examinations more or less in accordance with the schedule. The other two removed from the area. A total of 336 reexaminations were made, an average of more than five examinations per person. The number ranged, however, from three in nine persons to fifteen in one case.

Twenty-six persons gave consistently negative results in a total of 103 reexaminations. In other words, 45 per cent had no discovered clinical or hemic relapses during the season. Seventeen of those negative on reexamination were persons who had had new infections, and two others had probably had recurrences of infections of two years before.

Thirty-two patients were positive sixty-eight times and negative 165 times, in a total of 233 reexaminations. Three of these thirty-two cases were new *Plasmodium falciparum* infections, five were recrudescences of the twenty-four new *Plasmodium vivax* infections, and the remaining twenty-four were recrudescences of recurring old infections. Of the latter, eight had only hemic relapses, nine had only clinical relapses, and seven had the two types at one time or another. The same proportion held in the new infections.

If one may judge from the small number of cases, parasites may at times be found in the peripheral circulation in about half the cases without producing clinical symptoms. An extreme case is patient 17, a child, aged 6 years, who was reexamined seven times. On six occasions parasites were found, and the spleen was slightly enlarged, but no rise in temperature was noted at any time.

No parasite counts were made, so that we are not sure that the number of gametocytes present in the circulating blood was sufficient to produce anopheline infection, but it seems probable that some of these patients were infective for considerable periods of time.

COMMENT AND CONCLUSIONS

We have shown that in new *Plasmodium vivax* infections approximately 15 per cent will recrudesce during the same year, after treatment with 4 Gm of quinine. In the following year at least 35 per cent will recur. The real percentage is probably higher. Thus, as many authors have shown, may occur no matter what method of treatment is followed. It would therefore seem unnecessary to give a long course of treatment in fresh infections unless one wishes to reduce the recrudescences to the absolute minimum, which is probably about from 5 to 8 per cent. Considering the difficulties involved in giving and assuring the faithful following of a long course of treatment, it is doubtful whether the results obtained are worth the effort and expense involved, at least in an organized campaign.

In *Plasmodium falciparum* infections, however, more than 80 per cent of our cases persistently recrudesced following the short treatment. Each recrudescence was treated, so that finally these patients took enough quinine—from 8 to 16 Gm—to effect a cure, and recurrences the following year were the exception.

On the other hand, in the spring recurrences of old *Plasmodium vivax* infections, 60 per cent of the patients had multiple attacks following the short treatment. Therefore, quinine treatment in these cases, which are important in the production of the summer epidemic, does not give such good results. A longer treatment might have given a lower percentage of recrudescences, although from Sinton's extensive experience, and that of others, this seems improbable. Some other drug would perhaps give better results in the treatment of the spring relapses.

The foregoing considerations suggest that in Spain new *Plasmodium vivax* infections may safely be given a short quinine treatment similar to ours, that *Plasmodium falciparum* infections should be treated for a longer period of approximately twelve to fifteen days, and that in chronic infections, or spring recurrences, one of the newer drugs should perhaps be used.

SUMMARY

A three year trial with a short treatment of 1 Gm of quinine sulphate daily for four days was made.

Of 234 new *Plasmodium vivax* infections, 15 per cent recrudesced, and at least 35 per cent recurred the following year.

Of 231 spring *Plasmodium vivax* recurrences of infections of the previous year, 60 per cent recrudesced following treatment.

Of 56 *Plasmodium falciparum* infections, 90 per cent recrudesced following the short treatment. The recrudescences were also treated, and only three recurred the following year.

It is therefore suggested that fresh *Plasmodium vivax* infections need only a short quinine treatment in the region under study but that *Plasmodium falciparum* infections should be treated for a longer period, while some other drug may be tried for the spring relapses.

49 West Forty-Ninth Street

Probably Four Eggs a Week—It is probably in the interests of good nutrition to consume at least four eggs (or egg yolks) per week unless there are reasons to the contrary. More liberal egg consumption is usually practicable and probably advantageous if the combined consumption of meats, fish and eggs is not allowed to become too high.—Sherman H. C. Food and Health, New York, Macmillan Company 1934.

A STUDY OF ONE HUNDRED CASES OF SKULL FRACTURES

FOLLOWED FROM FIVE TO THIRTEEN YEARS

DANIEL E. EARLEY, MD
CINCINNATI

My purpose in this report is to present a study of the condition of patients several years after a severe skull fracture. An attempt has been made to determine the effect of age, type of skull fracture, and treatment on the ultimate general condition of the patient.

The mortality in a large series of skull fractures treated in this clinic was studied by Dr. B. N. Carter in 1927. He found a total mortality rate of 37.2 per cent in 389 cases irrespective of associated injuries and length of time the patients survived. Excluding the cases that were moribund or obviously hopelessly injured, the mortality rate was 18.1 per cent.

TABLE 1—Summary of the Effect of Age on the Hundred Cases Studied

Age	Cases	Complete Recovery	Partial Recovery	Incapacitated
1-20 years	38	27	10	1
21-40 years	33	22	13	3
41-60 years	18	9	6	3
61-80 years	7	5	2	0

At that time Dr. Carter also outlined the method of treatment employed in the series of patients on which the present report is based. Patients with the following conditions were operated on as soon as practicable: (a) compound fractures, depressed fractures, and compound depressed fractures, (b) extradural hemorrhage or localized subdural clot, and (c) persistent weakness of an arm or leg.

Patients not requiring immediate operation were treated in the following manner. Repeated lumbar punctures were done both as a therapeutic procedure and as an indicator of the degree of intracranial pressure. On the results of this procedure subsequent therapy was based. If the intracranial pressure was

TABLE 2—Study of the Effect of the Type of Skull Fracture on the Hundred Cases Studied

Type of Fracture	Cases	Complete Recovery	Partial Recovery	Incapacitated
Vault	35	25	9	1
Basal	25	13	10	2
Vault and base	21	14	5	2
Extradural hemorrhage	5	3	2	0
Compound depressed fracture	12	7	4	1
Subdural clot	1	0	1	0

controlled by lumbar punctures, they were repeated as often as indicated. Cases of increased intracranial pressure that did not respond to repeated lumbar punctures were treated by subtemporal decompressions.

The 100 patients studied in this report suffered their injuries from five to thirteen years prior to the follow-up examinations. Patients who had no subjective signs or symptoms and no positive physical or neurologic manifestations were considered completely well. Patients who had subjective signs or symptoms or who had positive physical conditions not of sufficient

From the Department of Surgery of the College of Medicine of the University of Cincinnati and the Cincinnati General Hospital.

seriousness to keep the patient from following his work were considered to have residual symptoms and to be partially cured. Patients who were unable to work because of some disability due to the head injury were considered incapacitated.

Of the 100 patients examined, sixty-three were completely well. Thirty-one had residual symptoms but were able to maintain a reasonably normal life. Six were incapacitated.

Of the thirty-seven partially cured and the incapacitated patients, nineteen had headaches that were severe and frequent enough for the patient to attribute them to the head injury. Fifteen had vertigo, which was brought on by movement of the head. Seven had defective memory. In three a traumatic psychosis developed, in one patient the psychosis disappeared two months after the discharge from the hospital, the other two patients are still confined to a sanatorium. In four, personality changes have developed. Three patients are having the petit mal type of convulsions, two had generalized convulsions, which continued for four years and subsequently stopped, two had generalized convulsions for five years, followed by petit mal seizures, which have persisted now for four years, two other patients were known to have epilepsy before their injuries, and their convulsions have continued. Five patients are still having diplopia associated with weakness of one or more extrinsic eye muscles. Thirty-one patients were bleeding from the ears at the time of admission to the hospital. The follow-up examination of these patients revealed seven with impaired hearing, and all seven had a persistent perforation of the tympanic membrane of the ear. Two of these seven patients had a peripheral facial palsy. Bone conduction was normal in all patients. Seven patients had loss of smell. Neurologic examination revealed six patients with facial palsy of the central type. Three patients exhibited weakness of one side of the body.

With regard to treatment, twenty-six of the hundred patients were operated on, fourteen, or 53.8 per cent, recovered completely, nine, or 34.6 per cent, partially recovered, and three, or 11.6 per cent, were incapacitated. The operations performed were

- 1 Subtemporal decompression for sustained high intracranial pressure, eight patients complete recovery four, partial recovery three, incapacitated one
- 2 Debridement and elevation of fragments for compound depressed fracture, twelve patients complete recovery seven, partial recovery four, incapacitated one
- 3 Craniotomy for extradural hemorrhage, five patients complete recovery three, partial recovery two
- 4 Craniotomy for subdural clot, partial recovery, one patient

Of the seventy-four patients receiving conservative treatment, forty-nine, or 66.2 per cent, completely recovered, twenty-two, or 29.7 per cent, partially recovered, and three, or 4.1 per cent, were incapacitated.

The fact that 37.0 per cent of these 100 patients with skull fractures who were followed over a period of from five to thirteen years showed residual symptoms reveals the seriousness of head injuries. It is possible that these figures are slightly high, owing to the fact that patients with symptoms are more apt to report back to the hospital than are those who are perfectly well.

Of the cases which do not require surgical operations it is my belief that (1) prompt and continued reduction

of increased intracranial pressure to normal, (2) bed rest in the hospital for a period of at least three weeks and (3) a long period of physical and mental rest after discharge from the hospital may materially lessen the distressingly high incidence of serious disability following skull fractures.

Clinical Notes, Suggestions and New Instruments

THERAPEUTIC USE OF LOCALIZED ALLERGY

PAUL D. GARVIN, M.D. AND GERALD M. FRUMESS, M.D. DENVER

During the last few years extensive studies have been made on the circulating antibody (atopic reagin) usually present in atopy as well as the reaction of the sensitized tissue when brought in contact with the atopen.

The discovery by Prausnitz and Küstner¹ in 1921 that the normal skin can be passively sensitized by the intradermal injection of serum containing atopic conditions has been utilized for the diagnosis of atopic conditions. Walzer² in 1926 demonstrated that the passive transfer site often reacts in the characteristic manner when the specific atopen is ingested orally instead of injected into the sensitized area.

The histologic picture of the allergic wheal has recently been studied by Kline and his associates.³ They find that the essential picture is an inflammation of the dermis and subcutaneous tissue, with edema, vascular engorgement and leukocytosis. At first the eosinophilic leukocytes predominate (first hour), but later the polymorphonuclear neutrophilic and mononuclear cells replace the eosinophils.

It occurred to us that advantage might be taken of such an induced inflammatory reaction with its consequent mobilization of defensive agents at a local site in the treatment of indolent ulcers.

Serum containing atopic reagin was obtained from E. R., a white woman, aged 24, who is highly sensitive to chicken egg protein. This is shown by the onset of an asthmatic attack, vomiting and an eruption about the face and mouth on ingestion of eggs, and further demonstrated by scratch tests, the Prausnitz-Küstner reaction and the Walzer reaction. Her serum always shows a high titer against egg antigen. Serologic tests for syphilis were negative.

The one case reported is of C. T., a white boy, aged 11 years, who had chickenpox in October 1934. Several vesicles became secondarily infected and a large ulcer resulted over the middle of the anterior surface of the left tibia, measuring 3 by 4 cm, irregular in contour and about 3 mm in depth, with undermined border and purulent exudate over the base. This ulceration was treated for two months in the outpatient surgery clinic of the Colorado General Hospital, with no improvement. Blastomycosis, tuberculosis and syphilis were excluded by laboratory tests. Personal and family histories were negative for allergy. The boy was referred to the outpatient dermatology clinic, Jan. 11, 1935, and a diagnosis of indolent pyogenic ulcer was made.

January 18 0.1 cc. of serum obtained from the girl sensitive to egg was introduced intradermally at each of four equidistant sites just outside the area of inflammation and about one-half inch from the edge of the ulcer. The patient had been told not to eat egg in any form for two days preceding and following the injection. Forty-eight hours after injection of the skin he was given three soft boiled eggs. Forty-five minutes after eating the eggs he complained of itching and burning in and around the ulcer. Within two hours the area around the ulcer was red and edematous, and the erythema and swelling later almost circumscribed the leg. In twenty-four hours the reaction had completely subsided, and the ulcer was considerably

reduced both in area and in depth. With no general or local treatment except the use of compresses of physiologic solution of sodium chloride to keep the ulcer clean it progressed to rapid healing. Seven days after the intradermal injections, the surface of the ulcer was level with that of the surrounding skin, epithelial islands were scattered over the surface and complete healing occurred in seventeen days. The patient was ambulant throughout the treatment.

The results that we obtained in this case have suggested the use of this procedure in other indolent conditions, and further study is being made. We make this preliminary report in the hope that a wider use of this procedure will prove or disprove its possible value.

GLANDULAR PHYSIOLOGY AND THERAPY

THE PATHOGENESIS AND PREVENTION OF SIMPLE OR ENDEMIC GOITER

DAVID MARINE, M.D.
NEW YORK

NOTE.—This article and the articles in the previous issues of THE JOURNAL are part of a series published under the auspices of the Council on Pharmacy and Chemistry. Other articles will appear in succeeding issues. When completed, the series will be published in book form.—Ed

Important contributions have been made during the last thirty years to the etiology and prevention of simple or endemic goiter. Progress in its prevention, wherever attempted, both in man and in animals, has been especially striking, and as the results are cumulative, greater benefits—indeed, complete prevention—can be predicted.

Extension of knowledge of the etiology has come about mainly through studies of thyroid chemistry, the correlation of anatomic changes with variations in the iodine content, interrelations of the thyroid with other organs of internal secretion, particularly the pituitary and sex glands, and the pharmacology, first of whole thyroid substance and later of thyroxine.

While goiter (thyroid hypertrophy and hyperplasia) is only the anatomic expression of the specific physiologic disturbance or deficiency, the anatomic changes are, however, a constant delicate and objective indicator of the course, degree and intensity of the disturbance. On this account a brief summary of the anatomic cycle offers a good background for the discussion of etiology.¹

This cycle may be represented schematically as in the accompanying chart.

So far as has been determined, this is the only morphologic cycle that the thyroid cell is capable of exhibiting. Thus the series of changes observed in simple or endemic goiter, in exophthalmic goiter, in compensatory hypertrophy following partial thyroidectomy, and following the administration of the thyrotropic hormone are all essentially identical. Many investigators² have asserted that there are several

different forms, even of endemic goiter, but I cannot find adequate support for such a view. Virchow's view,³ that the various morphologic forms of goiter are only terminal metamorphoses of a single initial type, more nearly embraces the facts.

The structural unit of the thyroid is the follicle. Normally it is a rounded, grapelike, closed vesicle distended with clear viscid colloid (thyroglobulin). The epithelial lining is composed of flat cuboidal cells (never higher than cuboidal) arranged in a single layer, the bases of these cells are attached to a delicate vascular connective tissue framework. The cells are of two types, as first determined by Langendorf⁴ (1) chief cells and (2) colloid cells, and the necessary intermediate stages. These two types of cell occur in varying proportions, but the chief cells in the normal gland always predominate. The proportion of chief cells to colloid cells can be varied and controlled experimentally, and because of this the two types are considered as indicating only different stages of secretory activity of a single cell type. The chief cell is the actively secreting cell and the colloid cell is the collapsed spent cell.

HYPERTROPHY AND HYPERPLASIA

Whenever the amount of thyroid tissue becomes insufficient to supply sufficient thyroid secretion whether from reduced iodine intake, or from increased demands or following partial thyroidectomy, compensatory hypertrophy occurs. This hypertrophy, whatever the contributing cause, appears always to be the result of direct stimulation by the thyrotropic hormone. This is characterized principally by a decrease in the stainable colloid and in the iodine content, by an increase in the blood supply and by a change in the follicular epithelium from low cuboidal and cuboidal to high cuboidal or even columnar. There are infoldings and plications of the lining epithelium, mitoses and new follicle formation if the stimulation is of sufficient intensity and duration. This entire series of hypertrophic cell changes may now be produced in the guinea-pig in from three to four days by injecting the thyrotropic hormone of the anterior pituitary,⁵ in the dog it occurs in about two

weeks following removal of three fourths of the gland and in the rabbit within a month when kept on a diet of cabbage⁶ or of alfalfa hay and oats⁷ of low iodine content.

INVOLUTION (COLLOID GOITER)⁸

When physiologic compensation occurs, whether as a result of increased iodine intake, increased secretory epithelium or decreased demands in the organism (decreased thyrotropic stimulation), the gland slowly or rapidly returns to its quiescent, colloid or physio-

logically normal stage. The anatomic changes in such a gland are the reverse of those which occur during hypertrophy and hyperplasia. The gland as a whole becomes firmer, the color changes from an opaque grayish red to a translucent amber red when involution is complete. The blood supply diminishes. Colloid (thyroglobulin) accumulates, fills and even distends the follicles. There is a rise in the iodine store, somewhat paralleling the increase in storable colloid. The columnar epithelium slowly or rapidly shrinks to cuboidal and finally flat cuboidal if the involution is complete. Just as the active hypertrophies may be arrested at any stage of their progress, so also involution may be arrested at any stage. The stroma becomes less prominent, from compression, decreased vascularity or absorption. The completely involuted thyroid (colloid goiter) is the closest condition to normal physiologically, chemically and anatomically that a thyroid which has once been actively hyperplastic can again assume.

The old view (Virchow, Berry) that colloid goiter is a degenerative process is disproved by the fact that such a gland is capable of undergoing hyperplasia (regeneration) and involution many times during its life history. This has been demonstrated both in man and in animals. Involution is usually accompanied by a decrease in the size of the gland. This is not essential, however, and frequently in man not only does the size not diminish but actual painful temporary enlargement may occur (so-called iodine thyroiditis), especially when iodine is given suddenly in large doses to individuals with actively hyperplastic (parenchymatous) goiters. The development of a colloid goiter from a normal gland by pressure distention of the follicles with colloid, I consider impossible.

All the evidence at present available indicates that the thyroid enlargement is always initiated as an active hypertrophy and hyperplasia. Distention of the follicles with colloid undoubtedly causes further enlargement in certain long standing goiters, of the type designated as struma diffusa colloides proliferans, which are incompletely involuted and yet oscillate between slight further hypertrophy and slight further involution.

ATROPHY

While involution or recovery is the usual termination of compensatory hypertrophy, it occasionally happens (notably in endemic cretinism) that the maximum degree of hyperplasia possible fails to bring about functional compensation and sooner or later exhaustion, atrophy and death of the epithelial cells ensue. This outcome is most frequently seen in goitrous endemic cretins, both in man and in animals, and occasionally in the late stages of exophthalmic goiter. The morphologic changes observed are best interpreted as the result of long continued hyperactivity of the cells without sufficient physiologic rest, a lack of the thyrotropic hormone or a combination of the two. In such glands the most striking changes are seen in the epithelium and stroma. In the first stages the picture is that of an extreme degree of active hyperplasia with only an occasional pyknotic or atypical cell mass. In the more advanced stages the cells lose their uniform arrangement in the follicle wall. Desquamation and disintegration of the cells may be seen in the same follicle with mitotic figures and normally hypertrophic cells. Nuclei of the affected cells show great irregularity, sometimes they are enlarged and hyperchromatic, sometimes small and pyknotic, but always variable in size and staining

intensity. The colloid is usually greatly reduced, although occasionally dense masses of colloid may appear to be embedded in the stroma with little remaining evidence of the original follicular epithelium. As the atrophic process continues, the follicle becomes reduced in size by cell death and advancing sclerosis, until the remaining epithelial cells appear as compressed nests of distorted cell masses. The stroma is always relatively increased and in some instances seems to be absolutely increased.

It has long been known that, in spontaneous Gull's disease, atrophy of the thyroid may occasionally occur as a progressive shrinkage in the size of the follicles without previous enlargement. The exact nature of such atrophies are still difficult to understand despite the fact that Allen⁹ and Smith¹⁰ have shown that removal of the anterior hypophysis causes a rapid shrinkage in all the elements of the thyroid and that such atrophic glands can be restored to normal or even be made hyperplastic by the parenteral administration of whole anterior pituitary or of hypophyseal extracts. On the basis of this work one could look on the thyroid atrophy in certain cases of Gull's disease as primarily due to a loss of the thyroid stimulating principle of the anterior pituitary, although there is important evidence against this view, whereas the thyroid atrophy of endemic cretinism is always preceded by parenchymatous goiter and is due to a primary thyroid exhaustion.

STRUMA NODOSA (ADENOMATOUS GOITER)

This secondary morphologic feature of goiter is restricted almost entirely to man and on this account it has been impossible to test experimentally any hypothesis regarding its mode of origin or nature. Wegelin¹¹ has shown that adenomas are rarely seen in the developmental stages of goiter and that the percentage of adenomas increases with the duration of the goiter. While the fetal rest hypothesis¹² may explain some instances (congenital adenomas), it is certain that the great majority arise from previously differentiated thyroid tissue and in their beginning are due to the same physiologic stimulus that causes the diffuse goiter in which they arise. Prevention of thyroid hyperplasia completely prevents the development of these adenomas. They usually begin in the deeper portions of long standing, partially involuted goiters that have been oscillating between involution and hyperplasia for years.¹³ Such secondary hyperplasias appear at first as islands of regeneration surrounded by quiescent colloid goiter. If the thyroid stimulation is sufficiently intense the entire gland will become hyperplastic, and in such glands the nodules or adenomas are temporarily masked.

A satisfactory explanation for these different rates of growth is not available, but it would seem that variations in the blood supply and lymphatic drainage are important factors, particularly because the normally cystic structure of the thyroid predisposes this tissue to greater pressure effects from stroma bands, colloid retention, cyst formation and the like. Thyroid adenomas are more analogous to uterine fibroids than other forms of new growths. Since they develop as a result of the same stimulus that causes the thyroid as a whole to undergo hypertrophy, so also they tend to exhibit the same cycle of cell changes (hypertrophy and involution), but much more irregularly and to a

lesser degree. They are also capable of selectively taking up iodine and of producing, secreting and storing thyroxine, though with less constancy and regularity than thyroid tissue under full physiologic control. In the late stages they become more autonomous, lose more of their physiologic attributes and become true tumors, this is indicated by the fact that 95 per cent of the malignant epithelial tumors of the thyroid arise from them.

In this brief summary of the principal and sequential stages of the morphologic cycle concerned in the developmental (parenchymatous) and recovery (colloid) phases of goiter, discussion of the multitude of secondary changes (except adenomas) has been purposely omitted. It is believed that this cycle is the only morphologic response to variations in functional activity of which the thyroid is capable and therefore that it is not specific for any given disease, although it is a constant and readily measured expression of the variations in the supply of or in the demands of the body for thyroid secretion.

What is known of the function of the thyroid may be summed up as follows. It provides the means through its specific iodine containing secretion for maintaining a higher rate of metabolism than would otherwise obtain, and also, through variations in its activity, it provides a means for varying the rate of metabolism to meet changing physiologic needs. That a very efficient mechanism exists for stimulating the thyroid by way of the blood stream has long been suspected. The existence of such a mechanism was assumed in order to explain compensatory hypertrophy of the remaining fragment following partial thyroidectomy or the enlargement of transplants located in any part of the body and their dependence for growth on the amount of the animal's own thyroid tissue removed. Marked hypertrophy of the anterior pituitary in individuals with endemic goiter has been known for nearly 100 years.¹⁴ Experimental hypertrophy of the pituitary following thyroidectomy was first demonstrated by Rogowitsch,¹⁵ but the first proof of a pituitary hormone regulating thyroid activity followed the demonstration by Allen and by Smith that hypophysectomy caused atrophy of the thyroid and Smith's later demonstration¹⁶ that implants of fresh pituitary restored such atrophic thyroids to normal or even increased activity.

Subsequent work by many investigators from many angles has led to the conclusion that probably the thyroid can be stimulated only by this pituitary hormone (thyrotropic). As already pointed out, the morphologic and chemical changes in the thyroid following injections of the thyrotropic hormone are identical with those seen in compensatory hypertrophy following partial removal or in the developmental stages of spontaneous goiter in man and animals.

While the thyrotropic hormone of the anterior pituitary appears to be the sole means of stimulating the thyroid, there is ample evidence also that the thyroid secretion exercises a great influence on the anterior pituitary, particularly as regards control of the production and excretion of its thyrotropic hormone.¹⁷ Thus, desiccated thyroid will prevent the loss of acidophilic granules and the pituitary hypertrophy that normally follows thyroidectomy, and iodine alone will restore the

acidophilic granules and greatly reduce the volume of the pituitary in animals with hyperplastic thyroids.

The thyroid and anterior pituitary glands are delicately balanced. Any deficiency in the thyroid secretion quickly stimulates the pituitary, either directly or by way of a nervous mechanism, to produce more thyrotropic hormone, and, conversely, supplying the thyroid secretion reduces anterior pituitary activity.

Any modern conception of the etiology of goiter must therefore involve consideration of the availability of thyroxine, the activity of the thyrotropic hormone and the interplay of these two substances as basic factors. Such a theory must also include all the conditions that influence the quantity and action of these two substances.

The principal clinical diseases associated with disturbance of function of the thyroid may be grouped as follows:

I. Thyroid insufficiencies

1. Simple goiter (endemic, epidemic, sporadic)

2. Myxedema

(a) Infantile (cretinism)

(b) Adult (Gull's disease)

II. Exophthalmic goiter

The discussion of exophthalmic goiter is not part of this paper, but certain features of this disease may be referred to for comparison. Exophthalmic goiter is not a primary thyroid disease. The thyroid reactions in exophthalmic and endemic goiter are, however, similar anatomically and are apparently the result of increased pituitary (thyrotropic) activity. The anterior pituitary is usually enlarged in simple goiter, while in exophthalmic goiter it is not. In simple goiter the pituitary stimulation is dependent on deficient thyroid secretion, while in exophthalmic goiter the pituitary stimulation, if present, is probably the result of a deficiency of some factor or factors related to the sex glands and adrenal cortex. Attempts to treat exophthalmic goiter with estrogenic substance, while not entirely negative, suggest that the essential deficiency is not the estrogenic hormone. Also experiments with cevitic acid,^{17a} a constituent of both the adrenal and the sex glands, have not established that this substance has any definite connection with the disease. In exophthalmic goiter the iodine supply is ample, while in endemic goiter this is deficient. The adequate iodine intake makes possible the hyperthyroidism, and this in turn may further depress gonadal functions. Endemic goiter occurs more frequently before sexual maturity, while exophthalmic goiter is more common after the age of sexual maturity, and the cases may be divided roughly into two groups: (1) those occurring in young adults and (2) those occurring during the decline of sexual life. Many students of exophthalmic goiter have been convinced that the primary deficiency in this disease lay in the gonadal sphere (sex glands and adrenal cortex), and the discovery of the possible pituitary link offers a rational hypothesis of how the gonadal insufficiency may stir up the thyroid.

Endemic goiter and cretinism are believed to be different degrees or stages of the same nutritional fault, and all the evidence indicates that they are primarily due to thyroid failure. Paracelsus¹⁸ was the first to emphasize this close relationship, which all subsequent work has confirmed. This relationship was perhaps

most briefly expressed by Morel¹⁹ is follows "Goiter is the first stage on the road to cretinism" Spontaneous myxedema (Gull's disease) in the light of recent work may be primarily a failure of certain functions of the anterior pituitary, particularly a deficiency of the thyrotropic and gonadotropic hormones, so that while the end result in myxedema on the one hand and that in cachexia thyropriva and endemic cretinism on the other are similar in that they have thyroid insufficiency in common, the thyroid insufficiency in the two diseases may be attained by different means There are important general differences between spontaneous myxedema and cachexia thyropriva For example, in Gull's disease exophthalmos does not develop and there is gonadal atrophy accompanying or even preceding manifestations of myxedema, while after thyroidectomy exophthalmos may occur and not only does gonadal atrophy not occur but increased sexual activity usually results, particularly in rabbits The sex gland atrophy of myxedema would now be considered as another indication of anterior pituitary failure, while the exophthalmos and increased gonadal activity of thyroidectomized sexually mature animals would be explained as due to pituitary stimulation

SIMPLE ENDEMIC GOITER AND CRETINISM

Occurrence and Distribution—Simple goiter (endemic, epidemic, sporadic) may occur in any land or fresh water animal with the ductless thyroid, although there are species and individual differences in its incidence in animals living in the same general environment Animals living in the sea are free from the disease On the seacoast generally, simple goiter is rare In man it occurs in all races, in all climates and at all habitable altitudes In the temperate zones there is a seasonal variation corresponding to the seasonal variation in the iodine store of the thyroid (Seidell and Fenger)

While goiter may occur anywhere, even in midocean, as on one of Captain Cook's voyages in 1772 (associated with scurvy), one of the most striking features is the increased incidence in certain more or less defined regions of the world—the so-called districts of endemic goiter The most notable of these districts are the Himalayan Mountain region of South Central Asia, the Alps, Pyrenees and Carpathian Mountain regions of Europe, the Andean Plateau and southeastern Brazil in South America, and the St Lawrence and the Great Lakes basin extending through Minnesota, the Dakotas and adjacent Canadian provinces and the Pacific Northwest including Oregon, Washington and British Columbia in North America²⁰ It will be noted that most of these regions are mountainous, although there are important exceptions Of greater importance is the occurrence of endemic goiter for the most part on the leached soils deposited from the last glacial period There is also general evidence of decreases in the incidence of goiter in many of the minor endemic goiter districts during the past 100 years in addition to the rapid decrease since iodine prophylaxis was introduced

There are many reports of the sudden occurrence of goiter in large numbers of men and animals—so-called epidemics In man these epidemics have for the most part occurred in new arrivals in military garrisons, in

institutions, in schools or in new settlements in districts where goiter was endemic These individuals usually recover from goiter on returning to nongoitrous districts Outbreaks are reported from time to time in the lower animals, for example in fish hatcheries, on poultry farms and in dairy herds Some of these acute outbreaks have been in goiter regions while others have not, indicating that with optimal conditions for its development goiter may occur anywhere

Age—Goiter develops more frequently before sexual maturity than in the older age groups The major periods in life when goiter in man most frequently develops are (1) during fetal life (congenital goiter), (2) during puberty, (3) during pregnancy and lactation and (4) during the decline of sexual life

Heredity is not an important factor in simple goiter The thyroid has such a wide range of physiologic compensations that its functional derangements may be compensated for in one generation

Beginning with puberty, goiter in man is much more frequent in females, but in districts of severe endemic goiter this sex difference may be masked In lower animals and in man before puberty a difference in the incidence of spontaneous goiter due to sex has not been definitely established In experimental goiter (alfalfa hay-cyanide) in rabbits, males are more frequently affected

The cause or causes of goiter have interested physicians from the remotest times, and in general the views concerning etiology have reflected the state of medicine existing at the time A great variety of physical and chemical agents and hypothetical goiter noxae have been brought forward as causal factors St Lager²¹ grouped them under forty categories Most of them are now of historical interest only, but some are of present-day importance Poverty, unhygienic living conditions, unbalanced diets, and lack of transportation are important indirect and contributing causes McCarrison²² states that in northern India it is an old saying that families who could afford the luxury of table salt were free from goiter This statement implied poverty versus riches, but today it would imply a source of iodine The idea of a goiter noxa has come down through several centuries This noxa has been interpreted in different periods as miasma or emanations from decomposing animal and vegetable matter, as a colloidal organic agent in water, or as various inorganic substances dissolved or suspended in water, particularly salts of calcium and magnesium,²³ fluorides, silicates and sulphides With the rise of bacteriology and protozoology, the view that the noxa might be a living organism or its toxin was extensively investigated McCarrison²⁴ believed that organisms of the colon group were causal factors Chagas²⁵ reported a type of endemic goiter in Brazil which he thought was due to a trypanosome (*Schizotrypanum Cruzi*) Subsequent work has shown that this infection may exist without thyroid enlargement and that the thyroid enlargement may exist without the infection That many toxins or poisons of bacterial or other origin may indirectly stimulate the thyroid to increased activity and visible enlargement is well known Thyroid enlargements are of frequent occurrence in early pulmonary tuberculosis, in secondary syphilis, in the acute fevers

and in many intoxications. The thyroid reaction in these conditions is now looked on as a part of the general defensive mechanism against infection, the thesis of infection as a causative agent would not explain the age, seasonal, geographic and sex distribution of simple goiter. No evidence exists that goiter may be transmitted by contact, nor is it possible to transmit the disease from animal to animal either through feeding or through injecting the tissues of goitrous animals. Toxins and infections could be contributing causes of goiter only in somewhat the same way that they may contribute to the onset of diabetes mellitus, i. e., by increasing the needs of the body for thyroxine or for insulin.

Water has been associated as the carrier of the goiter toxin by all peoples from the remotest times.²⁶ All the experiments so far conducted with water have yielded negative or doubtful results. These results could be as easily interpreted as indicating a deficiency of some essential element, iodine, as indicating the presence of some specific substance. It is not in accord with the facts to state that water in goitrous regions is always polluted. There is the interesting experiment of Portland, Ore., where the incidence of goiter rose sharply after the introduction of the water from Mount Hood, which, from the standpoint of organic contamination, is one of the purest of waters.

One substance in water, calcium, stands out as an important factor in goiter and has been considered an etiologic factor for more than a century.²⁷ The high calcium content of water in many goiter regions is significant, but there are many areas where the calcium content is high without goiter and other areas where the calcium content is low with goiter. This would indicate that calcium is not an essential factor, though it probably is an important contributing factor.

A low iodine content of water, food and soils in regions where goiter was common was first established by Chatin.²⁸ His work was unfortunately discredited and further advance was blocked for forty-five years, until Baumann²⁹ and his pupils discovered the normal occurrence of iodine in the thyroid. Hirsch's³⁰ criticism of Chatin's work may be quoted as representative of the prevailing opinion up to the time of Baumann's discovery.

A short lived opinion was that advocated by Chatin (before him by Prevost and Maffoni and after him by Marchand and Fourcault) to the effect that the cause of goiter and cretinism lay in the absence of iodine in the drinking water and in the air. Chatin pointed to his numerous inquiries which showed that wherever the amount of iodine was relatively large, as in the basin of the Seine, Yonne and other rivers, the two diseases were unknown, that they both became prominent with a smaller amount of iodine, as in the Rhone valley, and that this inverse ratio obtained with even greater force in the valley of the Isere. If Chatin's theory is true it would then remain a question, and a very doubtful one, whether iodine has a prophylactic power against goiter as well as a curative.

Virchow³¹ also voiced his opposition to the idea that the absence of a substance could be a causal factor in goiter and insisted that the active agent must be a positive factor.

Deficient chlorides (also indicating a low iodine content) in waters of goiter regions was pointed out by

Eulenberg.³² Today Chatin's observations have been generally confirmed by all workers, including McClelland³³ and Remington³⁴ in this country, von Fellenberg³⁵ in Switzerland, and Hercus³⁶ in New Zealand.

The two positive contributions that have come out of all the early work on the etiology of goiter are (1) the high calcium and (2) the low iodine content of water in districts of endemic goiter.

Most of the recent experimental work has tended to add further support to both the low iodine and the high calcium intake as factors in the etiology of goiter.

The part that calcium plays in goiter development is not understood, although the recent experimental work of Tanabe,³⁷ Hellwig,³⁸ Thompson³⁹ and others abundantly confirmed the older geological and chemical studies and established the fact that an excessive intake of calcium in some manner increased the goiter-producing effect of a given diet. There is some evidence that it acts partly by neutralizing the effect of thyroid secretion, that is, by creating a relative insufficiency of iodine. Thus, Zondek and Reiter⁴⁰ showed that the metamorphosis of tadpoles by thyroxine was notably delayed by adding a soluble calcium salt (CaCl_2) to the water. The work of Abelin⁴¹ and others showed that calcium greatly lessened the metabolic effects of thyroxine, that is, animals (rats) given an excess of calcium in a given diet showed much less effect from thyroxine administration than did the controls. The work of Tanabe showed that when excessive amounts of calcium chloride were given to rats in the drinking water, together with a low iodine intake, enlargement of the thyroid occurred. Hellwig has confirmed this observation. More recently Thompson has further extended this work with calcium and has demonstrated that calcium carbonate is increasingly effective the lower the iodine intake, she has further shown that always with a constant iodine intake the thyroid reaction is greatly increased by increasing the calcium intake. What effect the phosphorus and magnesium levels have on this action of calcium in blocking the action of thyroxine is not known. The parathyroids are constantly enlarged in the experimental (low iodine-high calcium) goiter of rats and also in the cabbage and alfalfa hay-cyanide goiter of rabbits.

A great many food factors are known to affect the thyroid. St. Lager stated that it was a common belief that a high fat diet was a factor. McCarrison, Mellanby and others have confirmed this view. Baumann and his pupils noted that feeding foods rich in iodine (codfish) caused a storage of iodine in the thyroid and that fresh meats caused a decrease in the iodine store. Watson also found that a meat diet caused hypertrophy of the thyroid. Marine and Lenhart showed that pig's liver was the most potent of a variety of meat products in causing thyroid hyperplasia in brook trout and dogs. Chesney and Webster reported that a diet consisting solely of cabbage often produced goiter in rabbits. This finding has been confirmed, but there are important

annual and seasonal variations in the goiter-producing capacity of cabbage. My collaborators and I have many times referred to the frequency with which thyroid hyperplasia develops in prepuberal rabbits maintained on a diet of alfalfa hay and oats. There are great differences in the goitrogenic action of different samples of alfalfa hay, which are related, but not entirely, to the variations in iodine content. We have frequently pointed out that methyl cyanide ("acetonitrile") materially augments the goitrogenic action of both cabbage and alfalfa hay diets and that traces of iodine entirely prevent the thyroid overgrowth with these diets. It should be pointed out that both cabbage and alfalfa have high calcium and relatively low phosphorus contents and that they do not produce goiter unless the iodine content is low.

In recent years, vitamin deficiencies⁴² have been brought forward as causal factors in goiter. There is no evidence that a vitamin deficiency plays any primary role, although there is some evidence that deficiencies of vitamin B complex and vitamin C are contributing factors. Radioactive substances in water have also been considered causal factors, but no positive connection has been established.

Halsted⁴³ first produced experimental congenital goiter in puppies by removing most of the mother's thyroid early in pregnancy. Marine and Lenhart⁴⁴ confirmed this and showed also that congenital goiter could be easily prevented in such experiments by giving the mother a few milligrams of iodine during pregnancy. The extensive studies of the relations of iodine to histologic structure in representative series of mammals including man have shown that this element was always lowered to a critical level before hypertrophic changes in the thyroid began.⁴⁵ It was further shown that hypertrophic and hyperplastic changes could be readily controlled by giving or withholding traces of iodine, in puppies 1 mg of potassium iodide administered by mouth at weekly intervals was more than sufficient to prevent thyroid enlargement, while control puppies of the same litter, living in the same kennel and partaking of the same food, developed large goiters.⁴⁶ Similar evidence of iodine controlling the growth of thyroid transplants located in any part of the body has been reported by Manley and Marine.⁴⁷

To sum up the evidence at present available concerning the etiology of goiter, I believe that the view that goiter is caused by a specific virus or toxin or by the presence of a specific substance may be permanently abandoned and that one is justified in concluding that simple or endemic goiter is a work or compensatory hypertrophy instituted immediately by the thyrotropic hormone of the anterior pituitary in response to the demands, normal or abnormal, of the body for thyroid secretion. The essential cause of simple goiter centers about the supply of thyroxine and the needs, normal or abnormal, of the thyroid for iodine. Since there is no evidence that the ability of the thyroid to build up di-iodotyrosine and thyroxine is lacking in such thyroids, one must conclude that goiter is a deficiency disease due to an insufficient supply of iodine. This iodine

deficiency may be relative or absolute and may result from (1) factors that increase the needs of the body for thyroxine, such as puberty, pregnancy, the menopause, certain infections and intoxications, exposure to cold excess of certain substances in the dietary, including fats, proteins and calcium (the ratios of the latter with phosphorus and magnesium are also important), and deficient oxidation (for instance, thyroid reaction in anemias or in the presence of oxygen deficiency such as occurs at high altitudes), (2) factors that interfere with the absorption or utilization of a normal intake of iodine, and (3) factors that bring about an abnormally low intake of iodine.

All the factors enumerated in group 1 are examples of relative iodine deficiencies. In specific examples, such as pregnancy, the relative insufficiency is assumed to be associated with increased physiologic demands. An excessive calcium intake might neutralize thyroxine or protect the cells against thyroxine, or the calcium effect might be due to altered ratios with phosphorus and magnesium. Deficient oxidation might result from a lowered oxygen transport, anemia or lowered oxygen pressure in the atmosphere.

Concerning the second group there is no knowledge. It has been suggested that the flora and fauna of the alimentary tract might divert the iodine intake. It has also been suggested that the thyroid cells, through age or heredity, might lose their capacity to build up di-iodotyrosine and thyroxine, but no one has obtained such evidence, and with a moderately extensive experience I have seen nothing that would support such a view.

Regarding the third group, the outstanding facts are (1) that in districts in which goiter is common the iodine content of the soil, water and foodstuffs is low, (2) that in experimental goiter a low iodine intake is essential for goiter development, and (3) that the addition of from 0.5 to 1 microgram (one millionth of a gram) of iodine daily will prevent the occurrence of goiter in rats.⁴⁸ Iodine effective in such amounts would appear to be acting in the realm of a true physiologic need rather than as a neutralizer of toxins or as an antiseptic.

While it does not seem likely now that a single positive agent—physical, chemical or biologic—will account for all thyroid hyperplasias and even though the iodine deficiency (relative or absolute) theory does account for all the known facts, nevertheless one must still consider the possibility that some positive agent may be found and must bear in mind that much of the advance so far made has been due to the zeal with which individual investigators have followed up different hypotheses.

PREVENTION

There is sufficient evidence to show that during the last century, in both the severely and the mildly endemic regions, the incidence of goiter has slowly decreased. This result is probably an indirect effect of the general economic betterment—higher standards of living, improved sanitation, larger varieties of food, control of infectious and contagious diseases, and, in particular, better and more rapid means of transportation. Prevost⁴⁹ especially emphasized the need for better transportation facilities as a fundamental factor in planning control.

Historically, the methods suggested for controlling goiter have reflected the views as to its cause prevailing at the time. Thus, when heredity was considered a causal factor, marriage with individuals from non-goitrous regions was recommended. Changing and purifying water supplies as a means of prevention have been practiced for more than a century, primarily on the theory that water was a carrier of the noxa, whether it was some inorganic or organic chemical substance or a living virus. The search for methods of prevention was one of the main purposes of the goiter commissions appointed by the Sardinian government in 1845, by the Austrian government in 1860, by the French government in 1863, by the Swiss government in 1908 and more recently by the Italian government.

The theory of Chatin²³ that goiter was due to a deficient intake of iodine would probably have quickly led to the prevention of goiter by supplying additional iodine if supporting facts of the physiology, pathology, pharmacology and chemistry of the thyroid had then been available. The keystone for this scientific background was supplied by Baumann and his pupils in 1896 when they discovered that iodine was a normal constituent of the gland. Within fifteen years after this discovery sufficient physiologic, pathologic, pharmacologic and chemical correlations of iodine with thyroid function were available to supplement the observations of Chatin and to establish an adequate scientific basis for large scale experiments in goiter prevention with iodine.

Such experiments were carried out (1909-1910) in a colony of approximately 400,000 brook trout, varying in age from newly hatched to 4 years.⁵⁰ It was demonstrated that iodine added to the water supply at its source in amounts not exceeding 1 mg per liter entirely prevented the development of goiter and brought about involution in those fish with hyperplastic thyroids. It was later shown that changing the diet from fresh pig's liver to whole sea fish (as the source of iodine) was equally efficacious. McClendon has recently pointed out that the low incidence of simple goiter in Japan is probably due to the widespread consumption of sea foods, particularly seaweed, among the inhabitants. Following the brook trout experiments, the administration of iodine in some form or manner has been extensively and successfully applied in the large scale prevention of goiter and cretinism in sheep, cattle, pigs and domestic birds.

All attempts to arrange large scale experiments in goiter prevention with iodine in man were unsuccessful until 1917, when through the efforts of Dr O P Kimball, a former teacher in the high schools of Akron, arrangements were made to carry out such experiments in the school population of Akron.⁴⁶ The simplest and cheapest method had to be used, and it was decided to administer 2 Gm of sodium iodide in 0.2 Gm doses distributed over a period of two weeks, to be repeated each spring and autumn. Reexamination of the pupils at the end of the first year revealed essentially the same striking preventive and curative effects that had been observed in the lower animals, and the generalization made from the work with fish, birds, sheep and pigs that goiter is the simplest, easiest and cheapest of all known diseases to prevent was equally applicable to human endemic goiter. Experiments in the prevention of human goiter were begun in Switzerland by Klinger⁵¹ in 1918 with such striking results that in 1922 the

Swiss Goiter Commission recommended the introduction of state-wide prophylactic measures against endemic goiter.

Iodine is effective in prevention when administered in any form and by any means. This fact introduces difficulties and advantages—difficulties in selecting the most convenient form and means and advantages in that prevention may be accomplished with certainty by the use of iodine in any form. Historically and quite unknowingly, iodine-containing salt (sea salt) was the first means of administration, and since 1920, when artificially iodized salt was first introduced in this country at the suggestion of Dr H G Sloane of Cleveland, it has largely replaced other means of administration for general, practical prophylaxis. During the seventeen years since large scale prophylaxis of simple goiter in man with iodine was begun in the United States, it has been extended to Canada,⁵² Switzerland,⁵³ Germany,⁵⁴ Austria,⁵⁵ Italy⁵⁶ and New Zealand,⁵⁷ with equally favorable results.

During the first years of goiter prophylaxis there was considerable opposition, both here and in Europe, because of possible untoward effects, especially that of aggravating or even causing exophthalmic goiter. During the past five or six years this criticism has largely disappeared. The reports of Plummer⁵⁸ and of McClure⁵⁹ showed a distinct increase in the number of goiter operations in the years 1926 and 1927 in Michigan and Minnesota. This increase occurred mainly in the group of patients with long standing adenomatous goiters (so-called toxic adenomas), who had undoubtedly received too much iodine. I have had an opportunity of investigating twelve cases in which physicians thought the exacerbation was entirely due to the iodized salt, but in each instance it was established that other preparations of iodine had been used at the same time. Coindet⁶⁰ had noted in 1821 that iodine administration to individuals with adenomatous goiter often had injurious effects. Kocher⁶¹ was perhaps the greatest opponent of iodine therapy in cases of adenomatous goiter, and Plummer,⁶² in a large series of carefully studied cases, clearly established that iodine, instead of bringing about a temporary remission as in cases of exophthalmic goiter with diffuse parenchymatous goiter, more often increased the metabolic rate. Undoubtedly much of the literature on "iodine-Basedow's disease" and Kocher's opposition to the use of iodine in goiter came from administering iodine in susceptible or latent cases of exophthalmic goiter presenting adenomatous goiters. There is sufficient evidence to show that there is a real danger in giving iodine to individuals with adenomatous goiter, and unquestionably the more concentrated iodized salts (from 1 10,000 to 1 5,000) cause injurious effects (iodine-Basedow's disease) in this particular group of patients, while such doses, as is well known, have no injurious effects in normal individuals or in individuals with simple parenchymatous goiter. The elimination of this group with long standing adenomatous goiter I believe will largely prevent

the occurrence of iodine-Basedow's disease and remove the most important objection to generalized iodine prophylaxis. In the Akron experiment, lasting three years, eleven instances of mild iodism and no case of exophthalmic goiter occurred in 2,190 girls between the ages of 10 and 20 years. Klinger in 1921 did not observe a case of iodism or of exophthalmic goiter in more than 1,000 children observed over a period of sixteen months. These earlier observations have been repeatedly confirmed and offer the best explanation for the decline in the criticism against iodine prophylaxis.

The daily amounts of supplementary iodine required for prevention of goiter obviously must vary with different districts, with different age groups, with different physiologic epochs of life and with different diets and climates. The normal requirements of the body for iodine are not yet known. It has been stated that from 0.04 to 0.08 mg probably would cover the normal daily needs of an adult.⁶³ The most commonly used iodized salts now contain an added quantity of from 5 (1/200,000) to 10 (1/100,000) mg of potassium iodide or its equivalent per kilogram of salt. In Switzerland the former concentration has been in general use for the past nine years, with no untoward effects. As recently pointed out by de Quervain⁶⁴ it has reduced the incidence of goiter in school children from as high as 100 per cent to 5 per cent and has controlled congenital goiter, but there has been no change in the incidence of goiter of pregnancy or of goiter in army recruits. These observations further illustrate that amounts of iodine sufficient to prevent goiter may be insufficient to cure goiter and also that the amounts of iodine administered were insufficient to meet the greater requirements for iodine in the physiologic epochs of puberty and pregnancy. I myself feel that the addition of 10 mg of potassium iodide per kilogram (1/100,000), because it takes care of a wider range of iodine deficiencies with no appreciably greater risk, is the concentration to be preferred. As Cameron⁶⁵ has pointed out, it would not be desirable to use minimal normal requirements of iodine, if these were known, because of the highly variable requirements previously referred to.

There are several side-effects of goiter prevention that may be mentioned. The first is the elimination of congenital goiter and cretinism. This result becomes manifest within the time limits of a single pregnancy, but in man it will require a complete reproductive cycle to provide full proof.

The second is the reduction in the number of individuals requiring partial strumectomy. This result is beginning to become manifest after ten years of general prophylaxis. McClure in 1934 reported that the number of thyroid operations in seven southern Michigan hospitals had fallen from 1,452 in 1927 to 591 in 1933, a drop of 60 per cent in thyroid operations as compared with a drop of 17 per cent in all surgical operations during this period.

The third benefit—the decline in the incidence of benign and malignant epithelial tumors of the thyroid—will likewise require another decade in the case of benign and longer in the case of malignant tumors before adequate statistical proof becomes available. The figures given by Wegelin⁶⁶ for malignant tumors of the thyroid in Berlin, where the incidence of goiter

is low, and in Bern, where it is high, illustrate the influence of goiter on thyroid carcinoma and indicate the change that must take place when the incidence of goiter in the tumor age group is reduced. In Berlin there were thirteen malignant thyroid tumors in 13,426 necropsies while in Bern there were 159 malignant thyroid tumors in 15,250 necropsies.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING ARTICLE HOWARD A. CARTER, Secretary

ELECTROSURGERY

A DISCUSSION OF INDICATIONS, ADVANTAGES,
DISADVANTAGES AND WARNINGS CON-
CERNING ITS USE

HARRY E. MOCK, M.D.
CHICAGO

In presenting this article I do not intend to dwell on the technique or attempt to add to the knowledge of men who have specialized in this method, but rather to present to the general profession certain surgical conditions in which electrosurgery has been tried and found good, and to point out both the advantages and disadvantages of this method of surgery. The Council on Physical Therapy has studied and evaluated many different kinds of electrosurgical machines and has placed their approval on a number of them. This does not mean that the Council feels that electrosurgery is the method of choice for the general man in a great many of the surgical conditions for which it has been recommended, either by manufacturers' agents or by certain authors who have more or less specialized in electrosurgery. It has become quite apparent that, if electrosurgery is to retain its proper place in the surgical world, the profession must be enlightened concerning the disadvantages as well as the advantages of this form of surgery.

Electrosurgery, or the application of certain electrical currents to the body tissues for surgical reasons, is no longer experimental but is rapidly becoming the procedure of choice in a limited number of surgical conditions. There are three end results which can be obtained by the application of certain electrical currents to body tissues: dehydration, coagulation and section, or a cutting effect. A different type of electrical current is necessary to obtain these various results. In dehydration, as the name implies, there is an actual drying out or shrinking of the tissues, while coagulation produces more destruction, a homogeneous granular debris, as when applied to sensitive tumor cells. In cutting, there is a rapid destruction of a thin line of tissue, with a separation resulting, quite similar to that obtained by incision with the scalpel.

There are a great many electrosurgical machines on the market. The majority of them will give these types of currents, although some may excel in one current and be deficient in another. In selecting a machine, the surgeon must bear in mind that constant improvements and certain refinements are being added to these machines for the purpose of making them fool proof or prolonging their usefulness, or to make the three currents uniformly adequate in the given machine.

It is not necessary for the surgeon to master the physics of the machine producing these currents, but

⁶³ Eggenberger, H. *Munchen med Wchnschr* 71: 972 (July 18) 1924.
⁶⁴ de Quervain, F. *Centralbl f allg Path u path Anat. (abst)* 60: 360 1934.
⁶⁵ Wegelin, C. *Handb d spez path Anat u Histol* 8: 306 1926.

it is imperative that every surgeon attempting to use electrosurgery should become thoroughly familiar with the effects on the tissues of these various currents. This can be obtained at first by experimentation on dead tissues and on the tissues of experimental animals. Naturally, continued use of electrosurgery in operative work adds to the surgical proficiency in the method. The mere possession of an electrosurgical machine by a physician in his office, or by a hospital, for his use, does not mean that that physician or the staff members of the hospital are competent to perform surgical operations. Surgical experience and judgment are still of paramount importance. Knowledge in the use of electrosurgery alone does not mean that one can enter one or all of the special fields of surgery through this gateway. One must have mastered thoroughly the special fields of surgery before one is competent to perform operations by means of electrosurgery. This statement is so obvious that it seems unnecessary, yet there are manufacturers' agents who are selling these machines on the premise that it makes surgery easy and can make a specialist out of any surgeon.

Three things have limited the use of electrosurgery, even in those surgical conditions in which it is definitely indicated and offers the greatest advantages and greatest safety to the patient:

- 1 The experienced surgeon has become so familiar with the use of the scalpel that he is slow to give up this method for the adoption of another method which requires more or less special training in its use.

- 2 Too many inexperienced surgeons have adopted electrosurgery, and have used it in special fields wherein they were not even specialists, with an ever increasing number of poor results and an accompanying condemnation of electrosurgery.

- 3 Many hospitals have bought electrosurgical machines, too often on the advice of the salesman rather than at the special request of a staff member deeply interested in the method. Lukewarmly, various members of the staff have tried to use the machines without first making themselves proficient in the method. The operations were not successful, and, naturally, the staff ceased to use electrosurgery.

Recently a surgeon from a neighboring city visited the clinic with which I am associated, for the purpose of observing electrosurgery in the case of malignant breast tumor. He stated that his hospital had two electrosurgical machines, but, for some reason, the staff was lukewarm about using them. On further questioning, it soon became evident that none of the surgeons on this staff had perfected themselves in the use of these currents. One must guard against over-enthusiasm in this method. My associates and I have learned by sad experience not to attempt operations by this method in fields in which the specialist's judgment and his familiarity with the parts involved are of greater importance than simply knowing how to use electrosurgery. Fortunately, there is an ever increasing number of surgeons trained both in their specialty and in the use of electrosurgery to insure an increasing use of the method in the limited number of conditions in which it is definitely indicated.

These warnings cannot be overemphasized. Ward¹ says:

As in any surgical procedure, the essential feature of success in the use of the electrosurgical method in the treatment of malignancy is the development of an accurate judgment as to the extent of the disease and a thorough knowledge of the current being used, and the extent of the after-slag with the chosen current. This is obtained by practice. It is impor-

tant, however, that any one attempting to develop the perfect technic should have a thorough surgical training. By no means can electrosurgical methods be picked up quickly and in a slipshod manner. One is dealing with a tremendous force which, when rightly applied, produces splendid results, but if carelessly handled, causes disaster.

Skallern,² from the standpoint of the specialist, in his discussion "Is Electrocoagulation the Best Method for the Removal of the Fauical Tonsil?" emphasizes these facts as follows:

It is the most difficult and dangerous method in the hands of the inexperienced. The dangers and difficulties are multiple in ratio to the lack of knowledge, and no one who is not capable of removing tonsils by other surgical technic and meeting all complications that may arise during or after the operation should ever attempt their removal by electrocoagulation.

ANESTHESIA IN ELECTROSURGERY

One of the drawbacks frequently mentioned in the use of electrosurgery is the danger of explosions when general anesthesia is used. It goes without saying that electrosurgery should never be used in the same room in which ethylene is being given. One should refuse to use it if ethylene was given in the same operating room within the last thirty minutes. On the other hand, I do not hesitate to use either ether or nitrous oxide anesthesia in all electrosurgical operations except those about the mouth and face. The combination of nitrous oxide and ether anesthesia is not used because, when combined, they are more explosive.

When the indication is for a general anesthetic in a thyroidectomy, performed by electrosurgery, I have used both ether and nitrous oxide on many occasions. The one precaution taken is that a wet blanket hangs between the ether or nitrous oxide mask and the field of operation. A sterile sheet covers this wet blanket. The same is true in breast amputations. This wet blanket should be tucked well around the mask and close to the sides of the patient's face, and down behind the shoulders, so that the ether fumes cannot get under the sterile sheet and run the slight risk of being ignited by the electrosurgery. Careful attention to these details makes the use of ether and nitrous oxide possible in all operations except those in the immediate neighborhood of the mask, namely, the mouth and face.

In the latter situations, a local anesthetic is always used. It may be preceded by morphine, scopolamine or sodium amytal. For the removal of small benign tumors or other lesions on the body, local anesthesia is usually indicated. Patients seldom complain of the electric current under local anesthesia.

WOUND HEALING

From actual clinical observations in a large series of malignant conditions of the face, neck and breast especially, I am convinced that the wound made by electrosurgery is just as free of sepsis as is true of scalpel surgery, but wound healing is slower and, the larger the wound, the slower is the healing. Furthermore, the resulting scar from the incision through the skin by electrosurgery, other things being equal, is just as good as the scar following the scalpel, but the skin wound heals more slowly. Because of this fact, unless there is definite contraindication because of the nature of the tumor, I always make the incision through the skin with the scalpel. In electrosurgery the skin sutures are left in situ for two to five days longer, depending on the extent of the incision. Provisions for drainage of

¹ Ward, G. E. Electrosurgery chapter 8 in volume 7 of *Lewis's Practice of Surgery* p. 10.

² Skallern, S. R. *Arch. Phys. Therapy* 13: 587 (Oct.) 1932.

serum should always be made when much tissue has been removed, and especially if much coagulation has been necessary.

Burgess of England and John D. Ellis of Chicago have done considerable experimental work in the healing of wounds in electrosurgery. Burgess³ says:

Provided that an equally rigid aseptic technique be adopted as is employed in scalpel surgery, my experience is that operations performed by electrosurgical methods—the cutting current for the incisional work and the coagulating current for all but the largest vessels, and using fine tungsten wire as the electrode—are attended by primary healing with a frequency at least equal to that of scalpel surgery. On theoretical grounds one would expect healing to be rather slow since with the cutting current, there must necessarily be some slight necrosis of the wound surface, however microscopic, which will require to be dealt with by the phagocytes as a preliminary step toward healing. I therefore usually retain the skin sutures two or three days longer than when scalpel surgery has been used, though I am not convinced that this is essential. The ultimate scar can be just as inconspicuous, as supple and as strong as after the scalpel, and some of the scars upon the face and neck of female patients of the inconspicuousness of which I, and they, too, are most proud, have resulted solely from electrosection.

Ellis⁴ writes:

Experimental cuts were made with both types of current on the skin of the human being, dog, rabbit and frog. The first three of these have a skin with a stratum corneum, and in the presence of this layer, some coagulation results before penetration of the skin can be accomplished, even with a pure cutting current. This coagulation does not necessarily interfere with primary healing, but only 60 per cent of the cuts produced in dog's skin healed by primary intention. The skeletal muscle and muscular layers of the stomach and intestine can be severed by a cutting current without coagulation. The phenomenon of vessel closure with a coagulating current is interesting, involving collapse, shrinkage and agglutination of the vessel walls without extensive thrombus formation. A large amount of thrombokinase seems to be liberated in the cutting of capillaries and small vessels. There are many serious errors to be avoided in the coagulating of vessels. Too rapid coagulation causes explosion and subsequent hemorrhage.

In coagulation of tissues, the specific resistance of the tissues varies tremendously, e.g., fat is more than eight times as resistant as muscle, making the direction of the penetration of deep coagulation uncertain and dangerous.

INDICATIONS FOR ELECTROSURGICAL TECHNIC⁵

Electrosurgery, from a theoretical standpoint, is an ideal method in the majority of major and minor surgical procedures. From a practical standpoint, however, its usefulness is limited by the cumbersome machine, by the lack of trained assistants in its use, and by the fact that in the majority of conditions the scalpel is just as simple and just as safe a method. Certainly, in the hands of the inexperienced in electrosurgery the scalpel is a much safer method in the average surgical operation. I am positive that electrosurgery will never replace the scalpel, scissors and artery forceps. There are certain surgical conditions, however, which I am just as positive can be handled better and more safely, from the standpoint of the patient, by means of electrosurgery.

The chief indications for electrosurgery are found in those cases of malignant conditions located on the skin, in the oral cavity, in the extremities, in the breasts, or in other locations where it is easy to use as an

adjutant to scissors and the scalpel. It is indicated in extremely toxic goiters for the same reason that it is indicated in malignant growths, namely, to seal the blood vessels and the lymphatics and to prevent the entrance of thyroid toxins into the general circulation. It has been used and is sometimes indicated in attacking certain septic conditions for the same reason. A notable example of this is complete excision of the necrotic core of a carbuncle from the back of the neck. It is indicated, according to certain authorities, for the removal of badly infected tonsils or for the removal of tonsils in debilitated patients. Next to malignant conditions, electrosurgery is chiefly indicated for the removal of moles, benign tumors on the surface of the body, and certain types of nevi. Finally, it is indicated in certain conditions in neurologic surgery, chest surgery, gynecology and rectal surgery, in which the elimination of hemorrhage, in order to facilitate the operation, is the chief desideratum.

Some authorities have advocated the use of electrosurgery for many other surgical operations, for example, in amputations, in incising the abdomen, in stomach and intestinal resections, in hysterectomies, in cholecystectomies,⁶ and in many minor operations. Space will not permit the discussion of these operations. It will take considerably more experimental and clinical work to convince the majority of surgeons, including myself, that some of these operations can better be performed by electrosurgery than by the usual methods.

The indications for electrosurgery can best be approached, first, from the point of view of the general surgeon and, secondly, from the point of view of the specialist. As a general surgeon, I have used electrosurgery in approximately 500 operations. I am convinced of its value in selected cases, for example, the following:

BREAST

Malignant tumors of the breast can best be attacked by electrosurgery for the following reasons:

(a) If, as many people believe, it is possible to disseminate cancerous cells by direct implantation on healthy tissue by means of the scalpel or by dissemination of the cancerous cells through the blood stream or the lymphatics to other parts of the body, any method of operation that will kill the cancerous cells if the tumor is accidentally cut into or which will seal the blood vessels and the lymphatics at the time they are sectioned is certainly the method of choice. Tissue cells that remain on the electrode are immediately coagulated or killed and therefore cannot be transplanted. The cutting current, especially if combined with a slight coagulating current, will not only section the tissues but also seal the blood vessels and the lymphatics at the same time. Thus electrosurgery, not only in breast tumors but in any other type of malignant condition, offers the best means of preventing the spread of the cancerous cells during the period of operation, provided the hypothesis concerning lymphatic and blood stream dissemination is correct. I realize that this is a disputed point.

(b) The operating time, after one becomes familiar with electrosurgery, can be reduced approximately one third. One can incise the tissues more rapidly with the cutting electrode than with the scalpel, owing to the fact that the smaller blood vessels are immediately sealed and therefore bleeding does not interfere with

³ Burgess, Arthur. *Lancet* 2: 1355 (Dec. 16) 1411 (Dec. 23) 1933.
⁴ Ellis, J. D. *Electrosurgical Incisions*. *Arch. Surg.* 26: 981 (June) 1933.

⁵ Throughout this article the term electrosurgery is used synonymously with electrosurgical methods, procedure or technique.

⁶ Thorek, Max. *Electrosurgical Obliteration of the Gallbladder*, *J. A. M. A.* 103: 169 (July 21) 1934.

the process. The larger blood vessels must be grasped with artery forceps. A dozen artery forceps containing these larger bleeding vessels can be touched by the coagulating electrode, resulting in sealing of the vessel grasped in the forceps in the same time that it would take a fast operator to ligate two of these vessels. It is rare for a vessel thus sealed to bleed again, provided one has not grasped too much of the surrounding tissue in the artery forceps. Time and again I have performed radical breast amputations without using more than two ligatures throughout the operation. Recently, an entire breast amputation was performed without the use of a single ligature. The chief saving of time, therefore, in a radical breast amputation by electrosurgery is found in this method of hemostasis.

(c) The absence of pain following a radical breast amputation by electrosurgery is so universally noted that it has caused frequent comment, both on the part of my associates and on the part of the patients themselves. Recently I have operated on the opposite breast in the case of a doctor's sister whose first breast had been removed by the scalpel. She commented time and again on the absence of pain in her second operation as compared with the pain she suffered following the first amputation. True, some patients still complain of pain, but the number who go through their convalescence without a single complaint is noteworthy.

Burgess³ in commenting on the advantages of electrosurgery, says

In comparison with scalpel surgery, electrosection has, I am convinced, certain advantages and foremost among these I would place the lesser amount of after pain, not only in the immediate postoperative period but throughout the whole course of wound healing. Dividing nerve fibers by this method seals over their ends in such a way as to render them much less sensitive than after being divided with a knife, and in extensive operation wounds, such as those of large amputations of limbs or radical breast operations, this difference is strikingly manifest.

(d) Shock and hemorrhage are less in these radical breast amputations when electrosurgery is used. The reduction of shock naturally follows the reduction of hemorrhage. The diminished afferent impulses along the nerve fibers account for further reduction of shock. Considerable heat is generated in the tissues from the electric current. By the careful protection of the already resected portion of the breast by warm wet packs, much of this heat can be retained. Without question, this lessens the shock. If one uses a machine that will give both a cutting and a coagulating current, it is possible to do a radical breast amputation without losing a noticeable amount of blood. Unless the operator pays particular attention to securing exactly the right type of current, there may be just as much loss of blood by this method as by the scalpel method. However, I have removed breasts without having a drop of blood on my gown at the end of the operation. In order to secure this result, one must take more time, but too often, in the haste to complete an operation, sufficient attention is not paid to securing this desired current.

In regard to this view, Burgess says

I am not convinced that hemorrhage is lessened to any great extent if the purely cutting current only is used. With this oozing from the capillaries is slightly less and is earlier spontaneously arrested, but vessels of any size require to be picked up with forceps much as in scalpel surgery, and either ligatured in the usual way or sealed with the coagulating current. Some high frequency machines deliver a current which is a compromise between the purely cutting and coagulating current,

and with these hemorrhage is undoubtedly less, but only because of the greater degree of coagulation produced over the entire wound surface, with its consequent lesser probability of perfect primary union.

In performing a radical breast amputation with electrosurgery, I always make the incision through the true skin with the scalpel. The incision starts at the xiphoid process, extends upward and outward to the lower angle of the breast, passes on either side of the breast—usually 3 to 4 inches from the nipple—and converges again at the upper angle of the breast, and then extends upward toward the clavicle, well above the anterior axillary fold, and curves outward onto the deltoid. This incision when the wound is finally closed and healed, prevents the scar from extending across the anterior portion of the axilla, a condition that usually limits the abduction and elevation function of the arm. For the same reason, the arm is never bound to the side of the body, but the patient is encouraged to abduct and elevate the arm over the head several times every day after the end of twenty-four hours. It is rarely that a patient has loss of arm function, and it is rare to have a swollen, painful arm, if this plan is followed out. The reason for making the incision through the skin with the scalpel is that the healing of the skin wound is undoubtedly faster than when the incision is made with the cutting current. Bleeding from this incision is slight and is soon checked when the cutting current is applied.

Electrosurgery is now used for the remainder of the operation, with the one exception to be detailed. By means of the cutting and slightly coagulating currents the skin and fat flaps are now dissected away from the breast, the inner flap of the skin being turned back until the midline of the body is reached, and at the upper angle until the inner third of the clavicle is reached. At this upper margin it is resected back until the clavicle itself is exposed. The outer flap of skin is dissected downward and outward until the entire axilla and the margin of the latissimus dorsi are exposed. One may now start the radical amputation of the breast. This may begin by electrosection throughout the insertion of the pectoralis major into the humerus and clavicle, next resecting the insertions of the pectoralis minor and turning these inward on the chest, exposing the axilla. Or, in many cases it may be more advantageous to start the amputation of the breast by cutting through the pectoralis major muscle attachments to the ribs, beginning near the xiphoid process and extending outward over the chest wall and likewise dissecting the pectoralis minor from the ribs when this muscle is reached, first lifting the entire breast off of the chest wall, leaving all the ribs exposed. These muscles can then be divided from the clavicle and the humerus, the axillary vein and artery having first been exposed to guard against damage to these. Since this dissection is done with the sealing of the lymphatics and the blood vessels, either of these procedures may be followed. The glands and areolar tissue in the axilla immediately below the axillary artery and vein, immediately above these vessels and above the brachial plexus, under the clavicle, and from all other spaces in the axilla surrounding these vessels, are now removed by blunt dissection, as is done when the scalpel is used. As soon as these vessels have been completely exposed by the removal of the glands and areolar tissue, further dissection of the axilla is performed by a combination of blunt dissection and the use of electrosurgery. As one becomes more proficient in electrosurgery, one can use the method closer and closer to these large vessels. There is a certain amount

of the work, however, that must be done by blunt dissection. This is the only weak point in the operation.

When the operation is completed, one has the entire breast and every bit of the areolar tissue and glandular tissue of the axilla completely removed, with the ribs, the axillary artery and vein, and the lower portion of the brachial plexus exposed. A counter opening is made at the lower angle of the outer flap, through which a soft drainage tube is inserted for drainage of this space. The operation is then completed by closing the skin flaps.

There are certain disadvantages that must be mentioned in connection with this operation by electro-surgery.

(a) Wound healing is somewhat slower. I have learned from experience to leave the sutures in place for fourteen to sixteen days rather than remove them on the tenth or twelfth day, as is done with scalpel surgery. In only one case has a wound broken completely open after the sutures were removed, and in this case they were removed on the tenth day.

(b) In the majority of cases there is more serous drainage than occurs with scalpel surgery.

(c) Hemorrhage may follow this method just as it may follow scalpel surgery. In only two cases has there been large hemorrhage, with formation of blood clots filling the axilla. There were no bad results in these two cases, except the delay in healing, due to its being necessary to open a portion of the wound for evacuation of these clots.

(d) Caution must be used in removing the pectoralis major and minor muscles from the ribs to prevent cutting or coagulating the intercostal tissue. In one case the current penetrated this tissue, opening the pleura. The small opening was immediately closed by suture, without any bad effect on the patient.

(e) Postoperative irradiation is now used in almost all of my cases. Dr. William Brown, radiologist, and I have become convinced that it is better to wait at least ten days before applying radium in these cases. Used earlier, the skin reaction seems more marked, and in one case there was marked sloughing of the skin. This would seem to indicate that there is more disturbance of circulation to the skin by this method.

Only one postoperative death in approximately 200 radical breast amputations, performed either by the scalpel method or by electro-surgery, has occurred. In this case the method used was electro-surgery. On the second day following the operation, a massive collapse of the left lung suddenly occurred and by the next day there was a serous discharge from the wound, cultures from which showed hemolytic streptococci. Death occurred at the end of the third day. At autopsy there was an opening into the pleural cavity, between the third and fourth ribs in the midaxillary line. A rubber drainage tube that had been inserted lay in proximity to this opening. It is my belief that the tissues at this point were weakened by the electro-surgery, and the pressure of the tube against this point caused an ulceration into the pleura. Since then, only the softest rubber drainage tubes have been used, and great caution has been exerted to avoid damaging the intercostal tissue.

THYROID

In 1930 I⁷ gave the first published report on electro-surgery in thyroidectomy. At that time only fifteen thyroidectomies had been performed by this method, but since then I have used it in approximately fifty cases. Its use is reserved for cases of marked thyrotoxicosis and for the purpose of preventing the spread of thyroid toxins into the general system by means of sealing the blood vessels and lymphatics while removing the goiter. For the average case that is not

highly toxic I prefer the scalpel. It seems that there is less serous secretion with subsequent drainage and better wound healing when the scalpel is used than when electro-surgery is used. In the majority of thyroidectomies I use a combination of the scalpel and electro-surgery. Much time can be saved in this operation by sealing all but the largest blood vessels with the coagulating current, reserving ligatures only for the latter. Without doubt, the use of the scalpel is more artistic and appeals to the surgeon more than the use of the cumbersome electrode. However, I am convinced that electro-surgery should be used in the extremely toxic cases. In thirty-five serious cases, with metabolism rates at the time of operation varying from 35 to 95 and showing extremely toxic symptoms, the operation was performed with electro-surgery without a single case showing the postoperative reaction or crisis that is so terrible to witness in some of these cases when only the scalpel is used. Several surgeons, by personal communication, have testified to the value of electro-surgery in these extremely toxic goiters. Dr. Martin Tinker⁸ is quoted by Clark⁹ as follows:

I have found the high frequency knife to be successful in goiter operations. Electrosurgical outfits have been used by a number of outstanding surgeons in this country for a good many years, especially in the management of malignancies. Several advantages have become apparent to many members of the profession, and I believe that shortly the electrosurgical unit will be considered a necessary part of every modern operating room, especially where much goiter surgery is done.

The advantages and disadvantages of electro-surgery in thyroidectomy, as set forth in my previous article, apply in almost all conditions wherein electro-surgery is used. For this reason, these are quoted in full.

Although this is too small a series of cases to justify positive conclusions, a few definite advantages are apparent.

1 The time of the operation is definitely shortened by this method through the sealing of the bleeding vessels rather than the use of the time-consuming method of applying ligatures.

2 In every case, even in the most serious, with marked cardiac involvement, there has been a complete absence of postoperative shock. One patient was in such extreme condition that his family physician called at the hospital just before the operation and begged both the patient and his wife to forego the operation, stating that he would surely die if submitted to this ordeal, yet the patient made an absolutely normal recovery, free from all shock and pain.

3 A convalescence so free from postoperative pain that even the patient remarks about the complete lack of suffering is almost the universal rule. This result, occurring in a group of patients who are usually emotional, given to complaints and often seeking sympathy, is especially noteworthy.

4 When one has used the electrosurgical method in the removal of a large number of malignant growths in breasts, tongues, lips and parotid glands, one becomes deeply impressed with the bloodless field, the absence of postoperative shock and the freedom from postoperative pain. The greatest impression, however, and the greatest sense of security, lie in the sealing of the blood and lymph channels simultaneously with the incision in and around the malignant growth. The old fear of opening up channels for the escape of carcinomatous cells to other parts of the body is at once eliminated to a great extent.

The same principle holds true in the removal of a very toxic goiter by the electrosurgical method. There has been no case thus far in this small series that has shown the least evidence of a postoperative thyroid toxicosis. It would seem logical to ascribe this to the same sealing of the blood and lymphatic channels, thus preventing the escape of toxic substances from the cut thyroid gland.

⁷ Mock H. E. Electro-surgery in Thyroidectomy. *J. A. M. A.* 94: 1365 (May 3) 1930.

⁸ Tinker M. B. *Surg., Gynec. & Obst.* 52: 508 (Feb. 15) 1931.
⁹ Clark W. L. in *Principles and Practices of Physical Therapy* Hagerstown Md. W. F. Prior Company 1934.

I am not yet ready to say that this will be my method of choice in every case of thyroidectomy. I am, however, convinced that it is by far the most rational procedure in all cases of malignant growths susceptible of being attacked by electro-surgery. For the same reasons, it would seem an equally rational procedure in malignant conditions of the thyroid or in severe cases of toxic or exophthalmic goiter.

DISADVANTAGES

1 The machine for the generating of this electric surgical current is large and cumbersome and is transported from one hospital to another with great inconvenience. It is an expensive apparatus and therefore will usually be purchased only by surgeons or hospitals interested especially in malignant conditions or by those who may come to recognize its value in thyroidectomies. Its general usefulness is therefore greatly limited.

2 The surgeon must have at hand a carefully trained assistant who understands the mechanism and who can manipulate the various switches that modulate the current from a light cutting stage, through intervening stages, to a heavy coagulating current. Unfortunately there are only a few persons thus far trained to operate this particular machine.

3 It requires considerable experience to use just sufficient current to make a clean-cut incision in the skin that will heal as readily and with as little remaining scar as follows a properly executed scalpel incision. With practice, however, this can be accomplished. If too strong a coagulating current is used in sealing the blood vessels, one may have a greater amount of serum drainage than is the rule when hemostats and ligatures are used. Here, again experience with the current is necessary to overcome this difficulty.

4 Care must be used not to allow the current to come in contact with a hemostat lying across the skin or a metal retractor, otherwise, cooking of the skin or of the tissue under the retractor will follow to a degree depending on the strength of the given current. This of course can be easily avoided.

OTHER MALIGNANT CONDITIONS

Electrosurgery is adaptable to a considerable number of other malignant conditions, as follows:

Malignant Conditions of the Tongue—All malignant conditions of the tongue susceptible for removal with the scalpel can be attacked with the cutting current, or better, the cutting and slightly coagulating current, equally well. As much as two thirds of the tongue has been removed by electrosurgery with very little hemorrhage and very little more sloughing than follows the use of the scalpel. A wide removal of the malignant tumor is indicated, and this can best be done by sealing the lymphatics and blood vessels with the electric current at the same time the tumor is removed. Extensive tumors, requiring resection of the mandible for their attack, have been removed by means of electrosurgery.

Radical dissection of the glands of the neck may be performed by a combination of scalpel and blunt dissection and electrosurgery. Removal of an isolated gland of the neck after it has been exposed can well be performed by electrosurgery.

Malignant Conditions of the Lips—There are many malignant conditions of the lips that can best be treated by radium. In many of these, consultation with a dermatologist is definitely indicated. There are certain malignant conditions of the lip, however, that must be widely resected. A number of these have been removed, the entire operation being performed by electrosurgery, including the incision of the skin. As a rule, a slight incision through the skin can be made by the scalpel, and then the cutting current is resorted to. However, with a pure cutting current quickly drawn through the skin, there is little delay in healing, and the resulting scar is practically as good as when the scalpel is used.

Malignant Conditions of the Face—A number of extensive malignant growths about the nose, cheeks, parotid gland and ears, and involving the eye, have been attacked by means of electrosurgery. Some of these have been so extensive that no effort at operation would have been made if scalpel surgery alone was available.

Some of these tumors can be completely excised and the wound closed. In one case of extensive malignancy of the nose and eyelids and involving the orbit, the entire dissection was done, including the enucleation of the eye and the cleaning out of the orbit, with electrosurgery. The wound was left open to granulate. Within two weeks there was such a good granulating surface that a pedicle graft was turned in to close the defect of the orbit, and Thiersch grafts were applied to the granulating surface of the nose. The resulting defect was not repulsive. This patient lived five years, and at the time of his death from pneumonia had no evidence of recurrence. Without doubt, electrosurgery offers the means of attacking some of these extensive, foul-smelling, ulcerating growths with considerable relief to the patient and the prolongation of his life. In many of these, surgery with a scalpel would be contraindicated.

In these lesions, as well as in malignant growths of the tongue and the lip and other skin cancers, one may prefer to coagulate thoroughly the entire cancer. By introducing the needle at various places around the margin of the cancer and working from the margin toward the center, and after the tumor is thoroughly coagulated, the cutting current may be used to incise the charred tumor mass. This method is indicated in certain of these tumors and is the method that is preferred by many operators. The wound remaining when a tumor is thus treated is usually left open and allowed gradually to close.

There have been a few cases of cancer of the breast of a year or more standing in which large ulcerated, foul-smelling areas have been removed by electrosurgery. Some of these have been recurrences following a radical breast amputation. These foul-smelling, ulcerated areas can be completely removed by means of electrosurgery with little hemorrhage if the current is damped, or made partly coagulating, and a large granulating area is left behind, which, in one case, healed sufficiently to allow skin grafting. Many of these patients can be relieved of their discomfort and suffering by this palliative operation, made possible only by electrosurgery.

Electrosurgery has been used as an adjunct to ordinary surgery in resection of the stomach, resection of the bowel, and resection of the rectum in the presence of malignant growths. After the mass is once freed, usually by careful scalpel and scissors dissection, its removal can be facilitated by resorting to electrosurgery.

NONMALIGNANT CONDITIONS

The chief nonmalignant conditions in which electrosurgery has been used have been moles, small benign tumors of the skin, excision of ulcerated areas following radium burns, two cases of plantar warts, and a few cases of large hemangiomas.

Recently a hemangioma that was slightly larger than an egg and was raised about half the height of an egg, and which was located on the front of the chest of a girl, aged 4 years, was removed. An elliptic skin incision was made by means of a scalpel around this nevus, completely outside the discolored area. The complete dissection of the nevus, down to the pectoral

muscles, was then made with electrosurgery. The cutting-coagulating current was used, and the entire mass was removed without a particle of hemorrhage. No ligatures were necessary after its removal. The skin margins were then undermined with the cutting current, and the wound was completely closed, giving only a hair-line scar, which, in time, will fade and will leave no noticeable defect. A similar nevus, about half the size of this one, was removed from a child's forehead with the same result. In the first case, Dr. William Brown, radiologist, was consulted before the operation was performed. It was his opinion that he could reduce the elevation of the nevus and the discoloration of the skin about 80 per cent, but could not eliminate the condition completely. He was consulted because I have referred several small nevi to him with their complete eradication by means of radium.* His opinion, therefore, was valued. Other nevi removed by this method have shown no signs of recurrence. In my opinion it is definitely indicated in the larger nevi that cannot be eradicated with radium.

Burgess says "In surgery of nonmalignant and non-infected conditions we are upon more debatable ground, and it has been in an attempt to ascertain for myself the possibilities of electrosection in general surgery that I have used it so largely and in such a variety of operations during the past six years." He has used the method a number of times in amputations of the extremities and stresses the point that there is less shock and less after-pain. He prefers it in operations on sensitive regions, such as the anal canal and says "The pain following operations for hemorrhoids, particularly that associated with the first action of the bowel, is markedly alleviated."

ELECTROSURGERY IN THE SPECIALTIES

Electrosurgery outfits have become a necessary part of the armamentarium of many of the specialists in surgery. There are certain operations in various fields wherein electrosurgery is now the only method used.

Brain Surgery—In 1931 Dr. Harvey Cushing¹⁰ published his article entitled "Electrosurgery as an Aid in Removal of Intracranial Tumors." Since then this method has been adopted by the majority of brain surgeons for attacking certain types of intracranial tumors. Cushing says

During the two years just elapsed since we hesitatingly began to employ electrical currents in craniocerebral surgery, 547 operations for tumors have been performed. Though for some of these operations the electrical methods were not essential, there were few of them, even when no tumor was found, in which they could not have advantageously been employed.

Dr. Ernest Sachs, in discussing a paper on this subject before a recent meeting of the American College of Surgeons, said "Electrosurgery is the most important addition to neurosurgical technic that has been devised in many years."

Dr. Loyal Davis¹¹ says

1 Electrosurgery is a distinct addition to the neurologic surgeon's armamentarium. It does not, however, completely supersede the well established principles of osteoplastic cranial cerebral surgery.

2 At present it may be employed to its greatest extent in the removal of meningiomas, in particular to the relatively inaccessible meningiomas.

3 The improvement of the use of electrosurgery in the treatment of gliomas offers the possibility for its greatest contribution to the surgery of the nervous system.

These authors and others who have written or spoken on the matter mention many of the disadvantages that have been previously brought out in this article. Davis points out the danger of electrosurgery leading to less meticulous care in the handling of these serious brain conditions. It must be stressed here, as elsewhere, that electrosurgery cannot be used safely in neurologic surgery unless one first is a thoroughly trained neurologic surgeon.

Eye—Surgical diathermy has proved itself in the field of the ophthalmologist. Walker¹² has said

Three years ago, surgical diathermy could have been dispensed with by the ophthalmologist and practically all the numerous valuable treatments which it provides could have been imitated and approximated by other treatments already at hand. Now, it has been definitely established, with the addition of separated retina to the list of surgical diathermic treatments, by the work of Larsson, Weve, Safar and others so that the ophthalmologist can hardly afford to ignore the subject longer from a practical standpoint, or, if surgically inclined, he should not be without recourse, either in office or hospital to at least the more economical surgical diathermic equipment.

Throat—Tonsillectomy by electrocoagulation has no doubt been abused. All of us have been questioned by the laity as to this easy, simple method. Skillern³ has best covered this subject.

I have talked to many laryngologists who are using this method, and they all tell me they have difficulty in removing the last vestige of tonsil, as it is very perplexing to differentiate tonsil from the surrounding tissue. If the experienced tonsil operator has difficulty, what must the occasional tonsil coagulator have when he reaches that remaining portion of the tonsil stump buried deep in the fossa and covered by a stiffened anterior pillar?

Dillinger, the champion of electrocoagulation for the removal of the tonsils, says "This method requires more skill and training than the ordinary surgical tonsillectomy, and no one except a throat specialist should attempt to use diathermy in the throat."

Beals speaks of the general practitioner being misled, because he believes he can easily master this apparently simple but in reality arduous method, and decries the unethical manufacturer adding chaos by sending out high pressure salesmen to sell to any one for the sake of a sale.

Coates, in discussing this paper, advocated that the laryngologist should include electrocoagulation to keep it out of the hands of those who are not qualified.

Myers reported thirty casualties and says that it is no method for the neophyte.

In spite of all this advice and warning by the leading men of the country, the manufacturers continue to install their machines wherever the salesman can procure an order.

When the public learns of the dangers and complications that may occur during the removal of tonsils by electrocoagulation, and, what may be even worse, leaving a buried focus of infection from an incomplete removal, it will shun this operation as it would a rabid dog, and the laryngologist will have difficulty in persuading the person with an otherwise inoperable condition to accept this method as the operation of necessity.

Occasionally cases are referred in which there is a history of advanced tuberculosis, exophthalmic goiter or myocardial degeneration requiring the removal of the tonsils. Electrocoagulation is the salvation of these patients.

10 Cushing, Harvey. Surg. Gynec. & Obst. 52:129 (Feb.) 1931.
11 Davis, Loyal. In Principles and Practice of Physical Therapy.

12 Walker, C. B. Am. J. Ophth. 17:1 (Jan.) 1934.

Again, there is the patient who has an actual horror of a hospital or a real fear of a general anesthetic but refuses a local anesthetic, as the sight of the instruments fills his very soul with terror. Here again electrocoagulation with its multiple applications of the needle cannot be mentioned in the same category with that of a clean surgical tonsillectomy by a trained operator.

I consider electrocoagulation a method of removing the tonsils that every laryngologist should master, as he will find it is necessary to remove them occasionally by this procedure. It should be spoken of not as the operation of choice but as the operation of necessity. It is the most difficult and dangerous method in the hands of the inexperienced. The dangers and difficulties are multiple in ratio to the lack of knowledge, and no one who is not capable of removing tonsils by other surgical techniques, and of meeting all complications that may arise during or after the operation should attempt their removal by electrocoagulation.

I have used electrosurgery in one case of carcinoma of the tonsil. This condition should be added to the definite indications for electrosurgery, and the same method is certainly indicated in all malignant conditions of the throat.

Chest—Electrosurgery is receiving a great deal of attention by specialists in thoracic surgery, especially for the removal of tumors or for the excision of a lobe when indicated, as, for example, in lung abscess. The following quotation from Matson¹³ shows the importance of this method in chest surgery.

My experience with the electrosurgical method has given me confidence in this method of cutting adhesions. Control of bleeding is the most dangerous problem and requires thorough knowledge of the character of the currents used. Electrosurgical cutting is accomplished without heat or smoke to disturb the view. There is a minimum of tissue reaction afterward, and while more complicated and technically more difficult than the galvanocautery method, it is without doubt a notable advance in this branch of surgery, which is being more widely employed.

Intrapleural pneumolysis by the closed method is not a fool-proof procedure with either the galvanocautery or the electrothermic method. The operator must be familiar with the appearance of the pleural cavity and at all times perfectly orientated regarding the nature of tissue to be cut. This training in the use of the thoracoscope in the pleural cavity is just as important to the surgeon or physiotherapist as a thorough knowledge of the cystoscopic image is to the urological surgeon. The operator should have experience with pneumothorax and must have surgical training.

Genito-Urinary—Electrosurgery has been used for years by many genito-urinary specialists for the removal of papillomas of the bladder and malignant growths of the bladder. In 1926 Harry Culver and I attacked a large, otherwise inoperable, carcinoma of the prostate and bladder wall with the cutting-coagulating current. The whole mass was completely excised, including considerable bladder wall. The patient, aged 76, was seen two years ago. He had lived seven years without any sign of recurrence and with the cystotomy wound completely healed. Corbus¹⁴ was a pioneer in the use of surgical diathermy in many different kinds of genito-urinary conditions. He has written extensively on the treatment of gonorrhea by diathermy and on the removal of bladder tumors by this method. In more

recent years, electrosurgery has come into prominence in genito-urinary work for transurethral resection of the prostate.

In 1933 Kretschmer¹⁵ gave his conclusions following 216 transurethral electric resections, as follows:

Age Incidence This paper is based on a series of 216 transurethral electric resections performed on 198 patients. The youngest patient in this series was 30 years of age and the oldest 89.

Postoperative Course Reactions following transurethral resections are generally very mild. Temperature reactions are less frequent than after prostatectomy, and, when they do occur, are less severe and do not last so long. In 117 resections in this series, the temperature lasted only from one to two days.

Hemorrhage As a rule, the urine remains blood tinged for a few days. Our efforts are toward sending the patient back to the ward relatively free from bleeding. As a rule, the urine is no longer blood tinged after the third day. In the occasional case it may be necessary to irrigate the bladder and to evacuate clots, but this depends upon the care exercised in controlling the bleeding at the time of the operation.

There was only one case in the 216 resections in which it was necessary to do a suprapubic for the control of hemorrhage, and that occurred early in the series. Primary bleeding can be controlled at the operating table. Secondary bleeding, that is bleeding which occurred between the tenth and the fifteenth day, was present in only seven out of the 216 resections. In six of them it was only necessary to evacuate the clots and irrigate the bladder with hot permanganate. In one case, a man with carcinoma of the bladder, it was necessary to resect the bleeding point.

Average Postoperative Stay in the Hospital No attempt was made to hurry the patients out of the hospital. The records show that the shortest stay in the hospital was two days, and the average stay six and one-half days. These figures refer to the straight resection cases.

The group prepared by suprapubic cystostomy had a slightly longer stay, since to the resection is added the time necessary for the suprapubic fistula to heal. These cases had an average stay of fifteen days.

Summary The results obtained justify the statements that have repeatedly been made to the effect that this new form of treatment carries with it a much lower mortality rate, and this in spite of the fact that many patients are operated upon by this method late in the progress of the disease, the delay having been caused because they had been told by the surgeon in charge that the case was inoperable. The records show that the mortality was only 2.77 per cent following 216 transurethral resections.

Dr. Harry Culver has furnished the following statement concerning the present status of electrosurgery in prostatectomy.

Electrosurgical methods applied to the genito-urinary tract have been in common usage for many years. It has been only within the last several years, however, that adequate electric current was available for other than electrocoagulation. Gradually loop resections of bladder tumor were done through an open bladder and even transvesical loop resections of obstructing prostatic carcinoma.

More recent developments have produced a current that will cut under water. This characteristic, together with a gradual development of nonelectrical transurethral operations, has resulted in the present status of transurethral resections of the prostate gland and certain tumors of the bladder.

All workers in this field are of the opinion that prostatic bars and prostatic carcinomas should be handled by the transurethral electro method, some being of the opinion that these two obstructions only should be handled by this method. The question of the removal of prostatic hypertrophies is one which, up to the present time, has not been thoroughly settled. There are enthusiasts of this method who operate on all hypertrophies, regardless of size or type if it is physically possible to pass the necessary urethral instruments, and a more conservative group that confines their transurethral operations to relatively

small hypertrophies, especially of the middle lobe type. Obviously there are many urologists whose work in this connection would place them all along the line between these two extremes. It would seem, after careful study of the present status of this method, that it is here to stay, but whether it will gain or lose in popularity will depend altogether upon the permanence of the relief obtained.

Gynecology—In conversations with many gynecologists, one is impressed with the fact that electrosurgery is not used in this field to the great extent indicated by certain authors. There are evidently only a few gynecologists who have used electrosurgery in the usual gynecologic operations, such as hysterectomy, oophorectomy, and salpingectomy. A large number of gynecologists have combined electrosurgery, either with x-rays or with radium, in attacking cervical carcinoma and large, otherwise inoperable carcinomas of the fundus. Here, again, surgical judgment, a thorough understanding of electrosurgical procedures and the specialist's knowledge in this field of surgery must be combined. The possession of an electrosurgical apparatus and knowledge of its use alone do not fit one to attack these major gynecologic operations.

Grant E. Ward¹ has recommended electrosurgery in the following gynecologic conditions:

Urethral Caruncle and Redundant Urethral Mucosa In treating either condition, a local injection of 1 per cent or 2 per cent procaine hydrochloride is first made, inclosing a wide margin beyond the disease, frequently requiring injection all the way around the urethral orifice. The caruncle is excised with a strong cutting-coagulating current.

Redundant mucosa is quickly destroyed by applying the monoterminial heating current directly to the surface, using a sharp needle electrode.

A thin, flat electrode, one-half inch long and one-eighth inch wide, is placed in direct contact with the mucosa. A slow biterminal current is preferred, as the entire depth of the mucosa should be destroyed.

Venereal Warts Local anesthesia is necessary here. The warts dry up quickly under the application of a monoterminial desiccating current.

Cysts Bartholin's gland cysts are opened with the cutting current with very little or no bleeding.

Infections in Skene's and Bartholin's Glands, causing recurrent infections in the urethra and cervix. A long, thin needle is inserted to the depth of the gland, the current turned on and continued until the tissues adjacent are blanched, indicating dehydration.

Endocervicitis In the more mild cases, the canal and external os are cleaned up with a biterminal current under local anesthesia.

Polyps Small vaginal or cervical polyps are readily destroyed with a short, thick monoterminial current.

Electrosurgery in hemorrhoidectomy has now been used in a considerable number of cases. In some of these the mucosa has been excised, exposing the varicose hemorrhoidal vessel, and this has been dehydrated or, in other cases, slightly coagulated, and an effort made to close the mucosa over the area. To be successful, the electric current used must be a very light one, and the operation is rather prolonged. If a strong coagulating current is used, there is danger of considerable slough and scar formation. In more recent years, electrosurgery has been used in connection with the clamp, quite similar to the old clamp-and-cautery operation, in the majority of the cases of large hemorrhoids. I am not convinced that electrosurgery, other than as an adjunct, offers many great advantages over other surgical methods of removal of hemorrhoids.

Ward¹ says

It should be noted in passing that large internal and external hemorrhoids can be dehydrated (desiccated) under local anes-

thesia in the office. One or two hemorrhoids require only local injections about them, whereas multiple ones necessitate injections around the anus and up above the internal sphincter. The sphincter muscle is then dilated, releasing the spasm which causes the hemorrhoid. A desiccating monoterminial current—a short thick spark—is preferable, being applied by a suitable needle electrode. The needle is thrown into the hemorrhoid and allowed to remain until the blood is dehydrated sufficiently as to clot. Larger hemorrhoids require clamping with any suitable hemostat, stagnating the blood and rendering dehydration and clotting more prompt.

In my experience there are few hemorrhoids that are suitable for operation in the office. From observation and from conversation with many other surgeons, I feel that an erroneous impression has been given to the profession at large to the effect that electrosurgery has made hemorrhoidectomy a simple procedure, possible of being carried out in the office.

Clark¹⁶ qualifies the use of electrosurgery in hemorrhoidectomy as follows:

The following technic for hemorrhoidectomy is almost identical with that of the clamp and cautery operation, except that electrodesiccation is used as the active agent instead of cautery.

Technic The usual preparation of the patient is carried out. Local infiltration anesthetization by classical technic may be employed, although in some supersensitive individuals a general anesthetic, preferably ether, is used. Caudal anesthesia is preferred by some operators. After stretching the sphincter muscle sufficiently, each hemorrhoid is pulled down in turn by means of suitable tenacula, and the pile is clamped at its base in the direction of the muscle fibers, which are at right angles with the anus. The pile is then electrodesiccated (by the technic described for other lesions) down to the clamp. The clamp is then removed and the hemorrhoid is permitted to slough away, or it may be excised at once not quite down to the clamp. The latter method is preferred. Postoperative hemorrhage is not greatly to be feared, there is no resulting cicatricial contraction, and as a rule postoperative discomfort is not great. In some cases, however, it is greater than in others. Patients should be hospitalized and remain in bed for a few days as a safe precautionary measure. The electrodesiccation method for removing hemorrhoids is an advance over the Whitehead ligature, clamp and cautery operations and the injection methods for the radical cure of hemorrhoids.

The electrodesiccation technic described has been found to be more satisfactory for hemorrhoidectomy than the more intense electrocoagulation method. The practice of passing the bipolar, high amperage current (diathermy) through a metal clamp after the hemorrhoid is engaged in the clamp, is not as satisfactory as the method described, owing to the possibility of unnecessarily electrocoagulating tissues adjacent to the hemorrhoids, the greater inflammatory reaction and the possibility of subsequent contracture of the lumen of the rectum.

There are many fissures, fistulas, papillomas, ulcers and certain malignant lesions of the rectum that can be attacked by electrosurgery. In resections of the rectum for a malignant condition, either with or without cholestomy, electrosurgery, when its use is thoroughly understood by the operator, offers the best method of attack. In localized malignant lesions here as elsewhere, great care must be exercised that the tumor is completely eradicated. If not, these localized growths are simply coagulated or cooked over, leaving the tumor base intact for direct extension or metastasis.

Skin—Without question, electrosurgery has been used in lesions of the skin to a greater extent than in any other field of surgery. It furnishes one of the simplest and easiest methods for the removal of moles. The monoterminial electrode is used, and the mole is dehydrated. It is natural that, from this simple pro-

¹⁶ Clark in *Principles and Practice of Physical Therapy* chapter 20 p 1

cedure, the operator is led on to attempt operations on many other skin lesions, especially epitheliomas. The majority of epitheliomas, however, can best be removed by the dermatologist by means of x-rays or radium. I believe therefore that electrosurgery should be reserved for those larger malignant skin lesions which are turned over to the surgeon by the dermatologist because the latter feels that surgery rather than the usual dermatologic procedures is definitely indicated. It is necessary to emphasize that too many malignant skin lesions are only half attacked by electrosurgery, in the hands both of the dermatologist and of the surgeon. Team work with the dermatologist is the best way for the surgeon to meet this situation. If either of them decides on using electrosurgery, the lesion must be widely excised, either with or without coagulation of the tumor proper. When coagulation of the tumor alone is done, it is impossible for the operator to know positively that he has completely eradicated the entire tumor.

Predicated on a thorough understanding of its dangers and limitations, electrosurgery attains its greatest scope of usefulness in surgery of the skin and mucous membranes.

Logical and sane advice is given by MacKee and Cipollaro¹⁷ in both benign and malignant conditions of the skin. Regarding verrucae keratosis, hypertrichosis, and moles they say:

Carelessness and ignorance when applied to medical diathermy may result in undesirable injury to the skin and even to the underlying structures. Surgical diathermy (electrosurgery) may cause injuries which are objectionable, painful, disfiguring and, at times, dangerous.

When employing electrocoagulation, the operator must take care that he does not destroy unnecessarily important, normal, adjacent tissue. Also, hemorrhage must be guarded against. During the application of the current, there is no hemorrhage because small vessels are occluded, but a large adjacent vessel may be damaged just enough to cause a severe postoperative hemorrhage.

The cutting current seals the small vessels but not the large ones. Hemorrhage from the large vessels can be controlled often by touching the vessel for a second or two with a strong desiccating or monoterminal coagulating current. However, it is preferable to ligate large vessels, either before or during the operation.

The coagulating and desiccating currents seal the lymphatic vessels completely. The cutting current does the same, but not so thoroughly. Advocates of electrosurgery believe that this instantaneous occlusion of lymphatic vessels prevents metastasis of malignant tumors. This is probably true when every part of the growth is accessible and the method is properly applied. As yet there has been no large collection of convincing statistics, however, to prove the contention. When dealing with an accessible malignant tumor, it is customary first to coagulate the tissue beyond the circumference of the growth by means of electrocoagulation or electrodesiccation, depending upon the size, depth and location of the lesion. The tumor is then thoroughly coagulated or desiccated, and the entire mass is removed with a curet or scissors (if small), or with the cutting current. Finally, the wound is electrodesiccated and dressed. It is usually advisable to remove tissue that has been thoroughly coagulated or desiccated, in order to prevent subsequent infection.

Electrosurgical enthusiasts believe that all biopsies, when there is any possibility of malignancy, should be made with the cutting current. This is not the opinion of such cancer experts as Francis Carter Wood, Douglas Quick, and such pathologists as Walter Highman, J. Frank Fraser, David Satenstein, and others, who are convinced that there is no danger in removing a piece of tissue from a malignant tumor with a sharp scalpel or a sharp biopsy punch as long as the lesion is not massaged, squeezed or roughly handled. Furthermore,

small pieces of tissue removed with a cutting current are likely to be so badly damaged as to be almost worthless for detailed microscopic study. With large pieces of tissue, the center is usually unaffected by the cutting current.

I would reemphasize the fact that biopsies can be obtained by means of electrosurgery which are equal to biopsy material secured by the scalpel. Dr. Howard T. Karsner¹⁸ states that "the thin film of coagulation is so slight that it does not interfere at all with biopsy studies, and, as a rule, there is less distortion of the tissues than is the case with scalpel biopsy." I would likewise refer to the article by Weidman and Guequierre,¹⁹ which also thoroughly supports this view. A word of caution, however, should be offered. If the bits of tissue are small, the injury to them may be such as to prevent satisfactory microscopic examination. Allowance should always be made for the zone of coagulation and destruction.

Continuing, MacKee and Cipollaro say:

The advocates of the cutting current aver that the incision may be sutured and that primary union will follow. This is true, but primary union very often fails. It is less likely to fail if the incision is freshened with scissors or a curet before it is sutured.

Major electrosurgery requires the same attention to asepsis as does major scalpel surgery. Minor operations do not necessarily require the same degree of asepsis. Nevertheless, it is advisable to employ the same care in this respect in minor surgical diathermy as in minor scalpel surgery, both during and after the operation. Even in such a simple procedure as the surgical desiccation of a small, superficial skin lesion, it is advisable, at least, to paint the area with iodine. If alcohol is used, the current should not be applied until the alcohol has been removed by evaporation or with a piece of gauze.

Keloids and hypertrophic scars are rather common subsequent to surgical diathermy, especially after electrodesiccation. It is well to inspect the scar weekly for a month or two and to apply radium or x-rays at the first evidence of hypertrophy.

CONCLUSIONS

1 Electrosurgery offers a distinct advantage over scalpel surgery in a limited number of surgical conditions.

2 Surgeons must understand the differences between the dehydrating, coagulating and cutting currents and must learn through much experimentation how to control and use these various currents before attempting to do electrosurgery.

3 Knowledge in the use of electrosurgery is of secondary importance to surgical experience and judgment. The possession of an electrosurgery apparatus and a little instruction by a manufacturer's agent does not fit one to attempt surgical operations by this method. No physician not thoroughly trained in scalpel surgery should attempt electrosurgery.

4 Electrosurgery is useful in many operations in the various fields of special surgery. Here again the specialist's knowledge and surgical experience are of paramount importance before attempting to use electrosurgery.

5 Electrosurgery is the best means of attacking malignant lesions of the skin, breast, the various orifices, and even the deeper malignant lesions after they have been exposed by scalpel surgery. It has proved of great value in neurologic, thoracic, genito-urinary, skin and thyroid surgery. It has a limited field of usefulness in many of the other specialties.

SATURDAY, JUNE 29, 1935

POLICIES ADOPTED BY THE HOUSE OF DELEGATES

The annual session of the American Medical Association held in Atlantic City, June 10 to 14, was extraordinary from the point of view of its contributions to the advancement of medical science and as a demonstration of a well-nigh perfectly organized meeting. Letters are pouring into the headquarters office expressing commendation of the Scientific Exhibit and of the lectures presented in the General Scientific Meetings.

The House of Delegates functioned efficiently and completed its business with such celerity that many observers commented on the apparent quiet of the proceedings. This was no doubt due to the fact that the reference committees were so well selected and so assiduous in the performance of their duties that most difficulties were ironed out in the committees. Many listened for hours to those representing various points of view, and the reports which they brought in took cognizance of these expressions and were therefore adopted without opposition from the floor.

In THE JOURNAL, June 22, appeared the reports of the first session of the House of Delegates, wherein resolutions were introduced on radio broadcasting, contraception, medical care and the teaching of medical economics. The House of Delegates encouraged the Board of Trustees to do its utmost to control the broadcasting of fraudulent claims for pharmaceutical preparations and to eliminate the broadcasting of claims for alleged cancer cures from Mexico. By the action of the House of Delegates the Board of Trustees was authorized to appoint a committee to study problems concerned in contraception and to present a preliminary report to the House of Delegates at the 1936 session. The chairman of the Legislative Committee described in his report, which appears in this issue of THE JOURNAL, the manner in which the Association has cooperated with the American Legion and the Veterans' Bureau in relationship to medical problems affecting these groups. He described also the steps that have been taken to bring various medical organiza-

tions into accord with the policies of the American Medical Association relating to economic problems. The Bureau of Medical Economics, pursuant to the action taken at the special session of the House of Delegates held in Chicago in February, presented at this time a report on more than two hundred plans now in operation in various parts of the country in an attempt to provide all the people with adequate medical care. This report of the Bureau, with various modifications, was adopted by the House of Delegates and will appear in an early issue of THE JOURNAL.

The actions of the House of Delegates as reported in last week's issue and in this issue of THE JOURNAL are given in considerable detail. It is desirable that all those who are interested in the policies of the American Medical Association make a thorough study of these reports and familiarize themselves with the problems concerned. Only to the extent to which all the membership of the Association is familiar with these activities and supports them can the Association function efficiently.

PUBLIC HEALTH UNDER THE ECONOMIC SECURITY BILL

Two sections of the Economic Security Bill¹ are specifically devoted to public health: title V, which deals with maternity and child welfare and the care of crippled children and which is to be administered by the U. S. Children's Bureau, and title VI, which has to do with public health programs in state and local communities and which is to be administered by the U. S. Public Health Service. Both sections provide for federal subsidies to states and territories in varying amounts and under varying conditions. In order to set in motion machinery for the administration of the act, a conference was called by the Surgeon General of the U. S. Public Health Service and another by the Chief of the Children's Bureau, both conferences meeting in Washington, D. C., immediately following the meeting of the State and Provincial Health Authorities of North America at Atlantic City. Representatives of the American Medical Association, including two trustees and two members of the headquarters staff, were invited and were in attendance at both conferences.

Title VI of the Economic Security Act provides ten million dollars for preventive medicine to be administered by the U. S. Public Health Service. Of this, two million dollars is to be used by the service itself for research purposes and eight million dollars for aid to states. It is contemplated that this eight million dollars shall be used for aid to the state and territorial health departments in providing adequate facilities especially for the promotion and administrative guidance of full time city, county and district health services, to strengthen the service divisions of state and territorial

¹ H. R. 7260 (Report No. 628) Calendar No. 661 Seventy Fourth Congress first session

health departments and to aid city, county and district health departments. The administrative plan advanced by the U S Public Health Service, as amended and accepted by the Conference of State and Provincial Health Authorities, provides six basic requirements for a state or territorial health department: namely, a qualified full time health officer, adequate provision for administrative guidance of local health services, acceptable vital statistics service, acceptable state public health laboratory service, special services for study, promotion and guidance of local activities for preventable disease control, and study, promotion and supervision of environmental sanitary control. Similar provisions are made with relation to city, county and district health departments.

The financial allotments are under five major divisions. First is a flat grant, under which \$400,000 will be allocated among the fifty-one divisions (that is, forty-eight states, the District of Columbia, Alaska and Hawaii), amounting to \$7,843 for each jurisdiction. This money is an outright grant, not to be matched by state funds. The sum of four million dollars is to be allotted to the states on a per capita basis and must be matched by state funds in two ways, that is, two million dollars on a per capita basis to be matched dollar for dollar from existing appropriations for state health work and another two million dollars allocated on a per capita basis but to be matched dollar for dollar with new appropriations, except that where a state has already customarily appropriated liberally for public health work the requirement of new appropriations may be waived and the state may receive its allotment by matching dollar for dollar with existing funds. The sum of \$1,200,000 is to be allotted for the purpose of equalizing the burden of public health work in accordance with economic conditions and needs of the states and territories, this having been determined by expressing by states the total income of the population on a per capita basis and determining the need of the individual state by its deviation from the median per capita income of the fifty-one state and territorial jurisdictions. Another \$1,200,000 is to be allotted to the states and territories on the basis of such geographically limited health problems as hookworm, malaria and plague, this is to be matched by state and local funds. An additional \$1,200,000 is set aside for purposes of training and provision of reserve personnel. Payments to states from allotments will be made dollar for dollar only to the extent that these funds are actually called for by plans submitted and approved.

To summarize. The outright gift to the fifty-one health jurisdictions and the equalization fund based on financial requirements need not be matched by state and local funds, other allotments must be matched, but exceptions may be made in the matching requirement with respect to the population-basis allocation of funds. The training fund will be administered by the U S

Public Health Service, allotments will be made to the several states but need not be matched.

The conference recognized that the most pressing need in connection with the administration of programs under the act would be qualified personnel. No adequate reservoir of qualified personnel exists. Therefore a special committee was charged with the duty of drawing up qualifications for personnel. These qualifications were accepted by the conference for four principal classes of personnel, namely, medical, nursing, engineering, and technical and sanitary. It was further recognized that there exists not only a dearth of qualified personnel but a total inadequacy of training centers for the training of those who may be desirous of meeting the qualifications established. Under the act the U S Public Health Service is empowered to strengthen existing training centers and to establish new ones for the training of personnel to carry out the purposes of the act in the state and local health jurisdictions. Sound progress depends on providing trained personnel, and haste in the expenditure of funds merely because they are available will be fatal to the success of the program. A provision in the act which makes unexpended funds available until the end of the second fiscal year seems to favor careful and considered deliberation in the execution of the purposes of the act.

A committee on uniform record forms also was created and presented a report to the conference establishing standards for uniformity in the recording and reporting of public health work. Since the act requires reporting to both the U S Public Health Service and the U S Children's Bureau in order to receive the quarterly allotments from federal funds, the necessity for uniformity of recording and reporting is manifest.

At the conference called by the U S Children's Bureau a plan was presented for carrying into effect title V of the Economic Security Act, which has to do with maternal and child health and care of crippled children and makes available \$3,800,000 for each fiscal year beginning with 1936. This is divided into a matched fund giving \$20,000 to each state, the District of Columbia, Alaska and Hawaii, and dividing among these jurisdictions in proportion to the number of live births the sum of \$1,800,000, as much of these two apportionments as may be used are to be matched dollar for dollar with state funds. There is also provided in this title of the act a free fund of \$980,000 to be allotted according to the financial need of the individual state as determined by the Secretary of Labor, taking into consideration the number of live births. Conditions required to be included in state plans for maternity and child welfare which shall be approved by the Chief of the Children's Bureau include financial participation by the state, administration or supervision by the state health department, such reports as the Secretary of Labor may require, extension and improvement of local maternal and child health services, cooperation with

medical, nursing and welfare organizations, and development of administrative services in needy areas

Services for crippled children are to be carried out through the Children's Bureau by means of a matched fund of \$20,000 to each state, the District of Columbia, Alaska and Hawaii, and no free fund. This program differs from the rest of the programs under the act in that it is not a program of public health and disease prevention but is frankly a program for the medical care of crippled children. It may not always be administered by the state health department as the other activities under the act will be. It contains the same general requirements as outlined for the maternity and child welfare functions, including cooperation with medical, health, nursing and welfare organizations. This is the part of the program that is most directly liable to be in competition with the private practice of curative medicine. This portion of the program is being studied by the Bureau of Medical Economics with respect to its possible relationship to the Bureau's special report adopted by the House of Delegates at Atlantic City.²

In the plans that the Children's Bureau has drawn up for administration of the maternal and child health provisions of the act are plans for cooperation with state medical societies and with nursing, welfare and other agencies and organizations through advisory committees and cooperative and educational activities. A similar cooperative relationship with county medical societies is proposed in carrying out the local programs.

The act provides for advisory committees to the Surgeon General of the United States Public Health Service and the Chief of the United States Children's Bureau. The intention has been declared to request official representatives from the American Medical Association to serve on these committees. The State and Provincial Health Authorities of North America adopted a resolution requesting publication in medical and dental journals of a statement outlining the general purposes of public health plans under the act and assuring the medical profession that they do not contemplate competition in the private practice of curative medicine.

The conference with the Public Health Service and that with the Children's Bureau were marked by a frequently expressed desire and determination to cooperate with the medical profession in the making and carrying out of plans. It is therefore important that each state medical society shall be prepared to cooperate with the state health officer, the responsible administrative head in each state or territorial jurisdiction, in the development of plans that accord with the principles of organized medicine. Such cooperation might be through the council of the state medical society or such other body as might be designated for the purpose.

Full information, including copies of the reports as amended and adopted, will be distributed to secretaries of state medical societies as soon as they can be prepared by the Bureau of Health and Public Instruction.

SYMPATHECTOMY FOR THROMBO- ANGIITIS OBLITERANS

Thrombo-angitis obliterans (Buerger's disease) affects predominantly young male adults. Anatomically the condition is characterized by a progressive thrombosis of the peripheral arteries and veins. The clinical picture is characteristic. In a more or less regular sequence there appear coldness of the digits, intermittent claudication, postural color changes, diminution or loss of pulsation in the peripheral arteries, localized pain during periods of rest, trophic changes in the digits leading to gangrene, and, sooner or later, involvement of the opposite extremity. The milder forms are amenable to conservative treatment consisting of rest in bed, contrast baths, postural exercises, careful application of heat, and vaccine protein therapy. In a considerable percentage of cases the condition is progressive. For these sympathectomy merits consideration.

Herrick, Essex and Baldes¹ demonstrated in carefully controlled experiments that, following lumbar sympathectomy in a dog, the flow in the femoral artery on the sympathectomized side was about twice as great as that on the intact side. Diez² began to perform lumbar sympathectomies for the cure of thrombo-angitis obliterans in 1924. Analysis of the early as well as of the late results in his series of seventy-five cases indicated that 75 per cent were definitely benefited by the operation. This work was soon followed by that of Adson and Brown,³ who reported 100 sympathectomies. Eighty-nine of these were bilateral lumbar sympathetic ganglionectomies and trunk resections, and fifteen were bilateral cervicothoracic ganglionectomies with resection of the upper portion of the thoracic sympathetic trunk. An "average degree" of improvement occurred in 80 per cent of the cases and a useful extremity in 76 per cent. Filatov⁴ collected 273 sympathectomies for thrombo-angitis obliterans performed between 1929 and 1934. With his own thirty-four cases and Hesse's fifty-one cases collected up to 1929 the total number was brought up to 379. Filatov's analysis of these cases indicates that 80 per cent were benefited and that 20 per cent were not. The mortality amounted to 4 per cent.

The proponents of the operation believe that the failure to obtain good results in 20 per cent of the cases

is to be charged to either a faulty selection of operative cases or to a faulty operative technique. The operation is not indicated for mild cases that respond to the conservative medical treatment. It is likewise contraindicated in cases of extensive thrombosis or massive gangrene. It may be used, however, in slowly progressing cases that do not respond to conservative measures. A good result from sympathectomy can be expected only when the blood vessels of the extremity are still capable of dilatation. Of the several tests, that developed by Brown and consisting of intravenous injection of typhoid vaccine gives the clearest indication as to the vasomotor response. Brown and Adson found that, whereas the mouth temperature of a normal person will increase on an average two degrees following vaccine injection, the temperature of the skin over the digits will increase from four to six. The explanation of the phenomenon, according to the authors, is that the peripheral arteries have been opened by inhibition of the vasomotor center and that more blood has been permitted to flow to the periphery. This test makes it possible to determine in patients with thrombo-angitis obliterans the presence of vasomotor spasm of the collateral vessels and unoccluded arteries. Unless the rise in temperature of the skin over the digits is two or more times greater than the oral temperature, the condition is to be considered inoperable. It was found at the same time that administration of vaccine for the purpose of producing fever and vasodilatation was most effective in relieving symptoms and encouraging the healing of abrasions and ulcers. However, while the vaccine therapy gave only temporary improvement, the increase in the blood flow to the extremity and the temperature increase following a sympathectomy continuously increased. Filatov calls attention to other valuable criteria of the test, namely, the subjective sensations of the patient and the improvement or the return of arterial pulsation.

The technical requirements for a successful sympathectomy imply the most complete desympathetization possible. Leriche's own experience with periarterial sympathectomy demonstrated the inadequacy of partial desympathetization. Brown and Adson insist on bilateral removal of the third, fourth and fifth lumbar sympathetic ganglions and the intervening sympathetic trunks. It should be emphasized that the recognition of the sympathetic fibers and trunks is not always a simple matter. It is not unlikely that some of the failures were due to the removal of the lymphatic trunks, which closely resemble the sympathetic trunks. It must be further emphasized that the operation is not only technically difficult even for the expert neurosurgeon but likewise a formidable procedure for the patient. The most serious complication is suppuration of the wound, which is particularly frequent in cases complicated by gangrene. The mortality even in the hands of the expert is not less than 4 per cent.

Current Comment

INTEGRATION OF THE MEDICAL PROFESSION

Recently there was introduced and passed in the legislature of the state of Oklahoma a statute integrating the dental profession. In the legal profession the movement toward integration has been under way for some years. Apparently there are movements afoot both in Oregon and in South Dakota for integration of the medical profession. This term implies the organization by statute of all licensed practitioners of medicine within a state into a public corporation, which corporation is authorized by law to determine the professional fitness of those who seek admittance into the profession in that state. The corporation would also be authorized to supervise and regulate the professional activities of every member of the profession. Thus it would determine who is and who is not eligible for admission, supervise the conduct of members, and reprimand, suspend or remove them when circumstances indicate the desirability of such action. Of course a member expelled from a corporation would thereby cease to be authorized to practice medicine. In such an integrated profession, every licensed practitioner would be entitled to vote for the managers of the corporation and would also be assessed for the cost of its management. An integrated medical profession would therefore take over the activities of medical examining and licensing boards. The movement would not apparently have great popularity among physicians, who are, of course, on a different basis than either dentists or lawyers, because of the cultists of various types who enter into the practice of medicine and because of the strength and usefulness of voluntary medical organizations. Certainly until the situation has been much more extensively studied and all the possibilities worked out, the medical profession will do well to avoid being drawn into any such movement.

A CHAIN LETTER HITS THE DOCTORS

Among the peculiar phenomena of the chain letter craze is one that has just come to the attention of the headquarters office of the American Medical Association. It is planned apparently to take advantage of the interest of physicians in organized medicine. The chain letter, which is headed with the name of the Association, suggests that the physician who receives it send \$10 in cash or in check to the doctor whose name appears on the top of the list and that he leave the name of that person off and add his own name at the bottom of the list. The list includes presumably ten names of men who are physicians or who are interested in organized medicine, many of them officers of county and state medical societies. An analysis of the list reveals in the center the names of two men who are not physicians and who will thus eventually receive considerable sums of money from the medical profession. It is assumed that few doctors will have minds so unscientific as to participate in a chain letter orgy.¹

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE EIGHTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 10 14, 1935

(Continued from page 2271)

Second Meeting—Tuesday Morning, June 11

The House of Delegates was called to order at 9 30 a m. by the Vice Speaker, Dr Nathan B Van Etten

Report of the Reference Committee on Credentials

Dr J D Brook, Chairman, reported that Dr E A Meyerding, Minnesota, who was alternate delegate for Dr J T Christison, wished to be seated as alternate delegate for Dr H M Johnson, who was not present and whose alternate could not serve. He moved that Dr Meyerding be so seated. The motion was seconded by Dr Isaac A Abt, Section on Pediatrics, and carried

Dr Brook stated that there was a total registration of 162.

Roll Call

It was moved by Dr C S Gorsline, Michigan, seconded by Dr Olm H Weaver, Georgia, and carried, that the signed attendance slips constitute the roll call of the House.

Presentation of Minutes

On motion of Dr J Allen Jackson, Pennsylvania, seconded by Dr William H Seemann, Louisiana, and carried, the House dispensed with the reading of the minutes

Report of the Reference Committee on Sections and Section Work

Dr T B Throckmorton, Chairman, presented the following report

The report of the Council on Scientific Assembly is clear, concise and to the point. It is with genuine pleasure that your committee approves in the highest commendable manner, the efforts of the Council in arranging the joint program in which the two greatest organizations in medicine on the American continent will participate, namely, the American Medical Association and the Canadian Medical Association. Such a program will redound to the glory of scientific medicine as it is known and practiced among the professions of these two nations, and it will do much to reflect to the world at large the good will, the professional feeling and the kindred interests that have ever existed between these two great medical associations.

Your committee likewise commends the Council on Scientific Assembly for the arrangements that it has caused to be made for the carrying on of the meetings of the various sections of the Scientific Assembly. That much time and effort have been spent in the preparation for proper meeting places goes without saying, but it should be borne in mind that the Council assumes the very great responsibility not only in supervising the work of the sections but also in seeing that suitable meeting places are provided for those who are in attendance on these meetings. For these efforts your committee wishes to commend the members of the Council on Scientific Assembly in the highest possible manner.

Evidently the program initiated last year of holding General Scientific Meetings on Monday and Tuesday of the week of the annual session of the Association met with favorable response for your committee notes that arrangements have been made by the Council to carry on the work so nobly begun. This too meets with the approval of your committee, for it believes that such meetings are a distinct step forward in the progress of scientific medicine.

The Council is to be further commended for the arrangements it has made for those persons who are interested in the

study of anesthesia, of the history of medicine, and of military medicine. These subjects, while of importance, evidently are not considered by the Council to be of such scope as to justify the establishment of a distinct and separate section for each of them, yet, classified under the Section on Miscellaneous Topics, these subjects can be brought to the attention of the profession in such a supervised and well directed manner as to assure the presentation of a well rounded program on topics that well merit a place on the program of the Scientific Assembly.

For all the manifold duties that the Council on Scientific Assembly has so ably performed during the past year, your committee wishes to express its heartiest thanks, believing that in so doing it but reflects the sentiment of the House of Delegates.

Respectfully submitted,

T B THROCKMORTON, Chairman
JOHN W AMESSE.
ISAAC A ABT
G HENRY MUNDT
HOLMAN TAYLOR.

On motion of Dr Throckmorton, seconded by Dr H B Everett, Tennessee, and carried the report was adopted.

Report of Reference Committee on Medical Education

Dr Irvin Abell, Chairman, presented the following report

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

1 The Council is to be commended for its thorough survey of the existing schools of occupational therapy. Its proposed Essentials of an Acceptable School of Occupational Therapy as outlined in Supplement A, pages 123, 124, 125 and 126 of the Handbook is recommended for adoption.

2 The activity of the Council with reference to the staffs of hospitals approved for intern training comprising only members in good standing in their local county societies is noted and its completed report at the next annual session will be awaited with interest.

3 Your reference committee records with approbation the progress of the Council in developing comprehensive plans for the identification of qualified physicians specializing in the various fields of medicine.

4 Your reference committee would urge the Council to speed its efforts to meet the urgent need for postgraduate work and would suggest that this could well be done by carrying the instruction directly to the practitioners in their various fields.

5 Your reference committee recognizes the present unsatisfactory methods of compensating radiologists for their service in hospitals and recommends that for the remainder of the sentence, line 6, page 120, of the Handbook, 'but that in no case should there accrue to the hospital a substantial profit over and above the reasonable cost of maintaining the department nor should the patient be exploited through excessive fees' the following be substituted: "but that in no case shall an economic arrangement be operative which is designed to provide a direct profit to the institution from private patients."

6 In view of the growing tendency to delegate purely medical functions to lay individuals, your reference committee would exhort the Council to continue its interest to the end that a definite position on the subject can be stated.

7 Your committee would urge the Council to continue its efforts to restrict the entrance of optometrists into any phase of medical practice.

8 and 9 Your reference committee visualizes the value of the complete report of the Council based on the resurvey of medical schools promised for next year and regards this work as equal in importance to any undertaken by it. The restriction of poorly prepared matriculants provides a genuine service to the student body as well as to the public.

10, 11 and 12 The Council reports commendable activity in the survey of hospitals, of sanatoriums caring for patients with tuberculosis and of schools for the training of physical therapy and laboratory technicians. Your reference committee would direct attention to the net gain in the number of approved hospitals for interns and residents as being of great import to the cause of medical training and service.

13, 14 and 15 Your reference committee desires to direct the special attention of the members of the House of Delegates to the importance of the factual data assembled in the Hospital Number of THE JOURNAL, issued March 30, 1935. These are of value not only to the profession but also to the lay people of every state involved, revealing, as they do, conditions that have a direct bearing on the cost of medical care.

**RESOLUTION MAKING MEMBERSHIP A PREREQUISITE FOR
QUALIFICATION AS SPECIALIST ON LIST OF COUNCIL
ON MEDICAL EDUCATION AND HOSPITALS**

The resolution adopted by the Arkansas Medical Society, April 17, 1935, presented by Dr Brooksher, would require pathologists and radiologists to become members of their respective county and state medical societies as a prerequisite for qualification as a specialist on the Council's list. Your reference committee recommends the approval of the resolution in principle, with the application of the requirement to all graduates of and after 1930.

RESOLUTION ON TRAINING OF INTERNS

The resolution introduced by the Council on Medical Education and Hospitals, June 10, 1935, urging officers and members of state and county societies to give due consideration to the problems of intern training in the approved hospitals with which they may be connected, is recommended for adoption.

**RESOLUTION ON ESTABLISHMENT OF COURSES IN MEDICAL
ECONOMICS IN ALL MEDICAL COLLEGES
IN THIS COUNTRY**

The resolution of the board of trustees of the Medical Society of the State of Pennsylvania, June 10, 1935, introduced by Dr Walter F Donaldson, urging the Council on Medical Education and Hospitals and the Bureau of Medical Economics to continue their endeavors until courses in medical economics have been established in all the medical colleges in the country, is recommended for adoption, with the suggestion that the Council in collaboration with the Bureau of Medical Economics outline the principles to be covered in such a course.

Respectfully submitted

IRVIN ABELL, Chairman.
WALTER F DONALDSON
GEORGE BLUMER.
W H SEEMANN

On motions of Dr Abell duly seconded and carried, the report was adopted by sections and as a whole.

**Report of the Reference Committee on Hygiene
and Public Health**

Dr J N Baker, Chairman, presented the following report:

Dr Holman Taylor, Texas, presented a resolution referring to broadcasting, which had been adopted by the State Medical Association of Texas.

The Reference Committee on Hygiene and Public Health gave that resolution careful consideration, both as to its content and as to its implications, and recommends that the House of Delegates of the American Medical Association substitute therefor the following resolutions:

WHEREAS The American Medical Association stands for and is willing to approve only the highest standards of broadcasting and

WHEREAS The American Medical Association acting through its House of Delegates has previously affirmed its opposition to any station or

program broadcasting material which is or might be detrimental to the health of the public therefore be it

Resolved That it is the sense of the House of Delegates of the American Medical Association that the broadcasting of matter coming from an adjoining country, which is untrue or dangerous or both as it pertains to the public health be brought to the attention of the Federal Communications Commission and be it further

Resolved That this commission be requested to take up through proper official channels any practices in radio broadcasting now existing or which may hereafter exist in an adjoining country in conflict with the foregoing declared principles, with the view of having such practices corrected.

Respectfully submitted.

J N BAKER, Chairman
W F BOWEN
J D HAMER.
V E STAMPSON
O S WIGHTMAN

Dr Baker moved that the report of the reference committee be adopted. The motion was seconded by Dr J Newton Hunsberger, Pennsylvania, and carried after discussion by Dr Olin West, Secretary, and by Dr Holman Taylor, Texas, who endorsed the substitute resolutions.

**Report of the Reference Committee on Legislation
and Public Relations**

Dr Charles E. Mongan, Chairman, presented the following report:

A resolution referring to radio broadcasting was submitted by Dr James F Rooney, New York, at the request of the Medical Society of the State of New York, and was referred to your Reference Committee on Legislation and Public Relations.

Your committee is informed that the Director of the Bureau of Investigation and the Director of the Bureau of Health and Public Instruction of the American Medical Association appeared recently before the Federal Communications Commission, submitted evidence of the evils of the present poorly regulated broadcasting system so far as the health of the public is concerned and presented their views with respect to the improvement of the situation. There is every reason to believe that the commission will do whatever may be possible under existing law to improve conditions. Your committee recommends, however, that this matter be referred to the Board of Trustees, with a view to promoting the enactment of such federal legislation and, if necessary, the adoption of such international conventions as may be necessary to cure the existing evil.

Respectfully submitted

CHARLES E. MONGAN, Chairman
E G WOOD
EDWARD M PALLETTE.
JOHN Z BROWN SR.
S P MENGEL.

On motion of Dr Mongan, seconded by Dr George W Kosmak, New York, and carried, the report of the reference committee was adopted.

**Report of the Reference Committee on
Miscellaneous Business**

Dr John F Hagerty, Chairman, presented the following report:

The Reference Committee on Miscellaneous Business, appreciating the importance of the catgut problem in surgical work, and the necessity for thorough study of all the problems connected with its use, viz., mechanical bacteriologic and allergic reactions of tissues, approves the resolution introduced by the Medical Society of the State of New York and recommends the appointment of a committee, under the supervision of the Council on Pharmacy and Chemistry, to investigate and formulate standards governing the manufacture of catgut for surgical use.

Respectfully submitted.

JOHN F HAGERTY, Chairman
D F CAMERON
L J KOSMINSKY

It was moved by Dr Hagerty that the report be adopted and Dr George W Kosmak, New York, seconded the motion. The Secretary suggested that the report be amended so as to

approve the appointment of the committee that is already in existence. Dr Haggerty and Dr Kosmik approved of the suggested amendment, and the report was then adopted as amended.

Resolution on Opposition to Continuation of Dick Scarlet Fever Patent

Dr J M Birnie, Massachusetts, introduced the following resolution, which was referred to the Reference Committee on Legislation and Public Relations

Resolved, That the Massachusetts Medical Society is opposed to the continuation of the so called Dick scarlet fever patent and the control of this patent by the Scarlet Fever Commission, and further that the delegates to the American Medical Association be instructed to bring this resolution before the House of Delegates

Resolution on Tests for Licensing All Drivers of Motor Vehicles

Dr Burt R Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations

WHEREAS The medical profession has an interest in public safety and in the preservation of life and the prevention of injury and

WHEREAS The motor vehicle has been responsible for an ever increasing loss of life and limb and

WHEREAS The damage to humanity may be curtailed by careful physical examination of motor vehicle drivers including stringent tests of sight and hearing as well as other physical and mental qualifications therefore be it

Resolved That the Section on Laryngology Otology and Rhinology requests the House of Delegates to appoint a special committee to study such legislation as may be required to regulate and prescribe appropriate tests for licensing all drivers of motor vehicles and to recommend such uniform legislation in the several states

Resolutions on Opposition to the Copeland Pure Food Bill and to Advertising of Drugs and Drug Products by Pharmaceutical Houses to the Laity

Dr John F Haggerty, New Jersey, introduced the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations

The delegates of the Medical Society of New Jersey have been requested to present to the House of Delegates of the American Medical Association the following resolutions, which were adopted by the board of trustees of that society, June 10, 1935

Resolved That the House of Delegates of the American Medical Association be requested to express its opposition to the passage of Senate Bill No. 5 (Copeland Pure Food Bill) and urge a Congressional investigation of the enforcement of the present Wiley Pure Food and Drugs Act and be it further

Resolved That the Medical Society of New Jersey is opposed to the advertising of drugs and drug products by pharmaceutical houses to the laity and requests the American Medical Association to refuse advertisements for any medical journal controlled by the American Medical Association or by its constituent state associations of pharmaceutical houses which resort to this practice.

The House recessed at 10 15 a m and reconvened at 10 45 a m.

The Speaker, Dr F C Warnshuis, took the chair

Report of Board of Trustees

Dr J H J Upham, Chairman, stated that the Board of Trustees desired to bring the following three subjects to the attention of the House

1 INTEGRATION OF MEDICAL PROFESSION

The Board of Trustees has been advised that at least two states have had under consideration, and that one still has under consideration, the matter of the reorganization of the medical profession along lines similar to those that are being followed in a number of states for the reorganization of the legal profession, namely, by a process of what is known as "integration" Under this process the entire profession of the state is organized by law, or in the case of the legal profession, in some instances, under direction of the courts, into a public corporation or its equivalent. Every licensed practitioner in the state is by reason of his status as a licensed practitioner a member of the corporation and entitled to a vote in its management. He pays such dues as the corporation imposes on him. The corporation through its proper officers, passes on the qualifications of every

person seeking a license to practice in the state, supervises their professional activities while they are licensed, and disciplines them as circumstances require in case of misconduct. Expulsion from the corporation and revocation of license are synonymous, for no one can practice who is not a member of the corporation.

It will be seen that under this system the profession is organized into a guild, as it were, and controls its own affairs, except that it has no right to pick and choose its members if they are morally and professionally qualified. It combines the functions of a medical licensing and examining board and of a state professional society. As has been pointed out, this kind of organization is being rather extensively followed by the legal profession. It has already been adopted by law in Oklahoma for the dental profession. It has been considered in one state and has been and still is being considered in another. It seems probable that other state associations will in due time give consideration to the form of organization described. For this reason, and in view of the revolutionary character of the change described, the Board of Trustees has deemed it best to submit it to the House of Delegates for determination of the policy of the Association with respect to it.

2 IMMIGRANT PHYSICIANS

At the recent Chicago special session the House of Delegates adopted a resolution directing that efforts be made to procure such legislative action as might be necessary to stop entirely the selective injustice to the American physician" resulting from the immigration into the United States of foreign physicians. This resolution was preceded by a preamble reciting that the immigrant physician was exempted from the limitations imposed by law on the immigration of foreigners into the United States, under the 1917 immigration law. The Board of Trustees has been advised that the immigration law of 1917 does not impose quotas on the several nations of the world with respect to the immigration of their nationals into the United States but limits the immigration of persons from foreign countries into the United States under prearranged contracts of employment. Physicians are exempted from the provisions of that act and may enter notwithstanding the fact that they come in under prearranged contracts. How many have done and are doing so, however, it has been impossible to ascertain. The quotas allotted to the several nations of the world for immigration into the United States were allotted by the immigration act of 1924, and under this act physicians are given no preference over other immigrants.

A study of the records of the Bureau of Immigration shows that the proportion of immigrant physicians entering the United States annually from and including 1931 to the number of physicians entering the medical profession by examination each year is lower than at any time since 1919, and the percentages in 1932 and 1933 were the lowest at any time since 1904, when records of this character first became available.

The Board has been advised that it seems practicable to exclude immigrant physicians, not by depriving them of any privileges now granted them by reason of their status as physicians, but by making them a selected group against which restrictive legislation would have to be directed. Such legislation would take the form either of depriving them of their right to enter the United States under contracts of employment prearranged or of imposing on them limitations not imposed on other quota immigrants. How far the number of immigrant physicians would be reduced by depriving them of their privilege of coming in under prearranged contracts of employment is uncertain because no figures are available to show the number entering in that way. Whether the Association desires to sponsor legislation undertaking to exclude physicians as a class even under the quota privileges to which they would otherwise be entitled is a matter involving such serious public policy that it has seemed proper to submit the matter to the House of Delegates for further consideration before entering on that course.

3 COMMERCIAL USE OF THE WORD "DOCTOR"

The attention of the Board of Trustees has been called to the commercial use of the word "Doctor" in connection with advertising, notably in connection with the advertising of shoes, in cases in which no doctor has had anything to do with the origination of the article advertised or with approving it from the

medical standpoint. It has been urged that the Association take steps to prevent the misuse of the word in that manner.

Obviously, the prevention of the misuse of the word "Doctor" must depend to a large extent on state legislation, since federal legislation can apply only to interstate and foreign commerce. Even with respect to state legislation, difficulty arises because of the present misuse of the word "Doctor" in other than commercial ways. Without considering such formerly honored titles as Doctor of Philosophy and Doctor of Laws, we now have Doctors of Osteopathy, of Chiropractic, of Naturopathy, of Podiatry, of Chiropody, and of other similar titles in which the doctor is to be debased. Legislation should begin, therefore, not in an effort to prevent the commercial misuse of the word "Doctor" but in an effort to procure the enactment of legislation that will regulate the conferring of the degree of Doctor and prevent its misuse for any purpose whatever. Along with this will go legislation to prevent fraudulent advertising of all kinds, whether by the misuse of the title "Doctor" or otherwise. The matter is respectfully submitted to the House with the recommendation that it approve legislation such as is suggested here and commended for the favorable consideration of the several state associations.

The Speaker referred the first section of the report to the Reference Committee on Reports of Board of Trustees and Secretary. The second and third sections of the report were referred by the Speaker to the Reference Committee on Legislation and Public Relations.

Report of the Reference Committee on Reports of Officers

Dr. Arthur J. Bedell, Chairman, presented the following report:

ADDRESS OF SPEAKER

Your committee hopes in opening this report, that it may be deemed within its prerogative to offer the sympathies of this House to the Speaker in the great bereavement which he has just suffered, and that his anguish may be somewhat appeased when he is reminded of the high regard in which all those who serve our Association in an official capacity are held.

Your committee notes with pleasure the details included in the Speaker's address and recommends that every member of the House of Delegates be enjoined, on returning to his constituency, to make a prompt, accurate and comprehensive report of the activities of this House of Delegates, since it is apparent that there is urgent need for bringing to every member and Fellow a clear and intimate knowledge of the policies and activities of the Association. Misunderstandings will be mitigated when the Fellows are intelligently informed.

ADDRESS OF PRESIDENT

Your committee has considered, with a deep interest, the splendid address of President Bierring. We wish to commend him for the breadth of view expressed and the scholarly grasp of the Association's activities which he has displayed throughout the nation. One of the gratifying impressions gained in his contacts with the members of our Association was their sustained interest and manifest devotion to scientific medicine.

Your committee reviewed the pronouncements made by him in relation to the activities of the various standing and special committees and concurs in his expression of appreciation of the fruitful services rendered by the General Secretary, the chairman and the members of standing and special committees. It particularly approves of his restatement that the development of adequate medical care is necessarily closely and intimately associated with the ethical conduct of all physicians. Such conduct has always been governed by precept and example, and to keep the professional shield untarnished is one of our sacred obligations.

Your committee heartily approves of the President's commendation of the work of the Council on Medical Education and Hospitals, especially as it applies to the inspection and reclassification of medical schools.

Your committee commends and approves his statement relative to Federal Emergency Relief. The organized medical profession is sympathetic with the humanitarian purpose of this movement

but looks with disfavor on the administration of its medical provisions by lay direction or its extension beyond the present emergency period.

With regard to the program contemplated by the national government in the extension of public health activities, your committee feels that the responsibility for carrying out a public health program is the duty of organized medicine, which is the only group qualified by training and experience to administer such a service so as to safeguard fully the public interest. Your committee is constrained to believe that it is not possible to maintain a high quality of medical service unless there are provisions for complete medical control of those who are to deliver the service.

Your committee wishes to place on record its approval of the devotion which Dr. Bierring has displayed during his strenuous year of administration and to thank him for the sustained interest which he has shown in the welfare of the medical profession of this great country.

ADDRESS OF PRESIDENT-ELECT

Your committee senses the fine discretion implied in the President-Elect's address in that he confines his remarks largely to commendatory statements with respect to the recent activities of the Association. Your committee notes, however, with pleasure that he points to a potential danger which lies in the continued growth of the Association in the direction of a separate entity, tending to remove its activities and purposes from that close relation with constituent societies necessary to healthy growth. He correctly suggests that the officers and Trustees are doing and should continue to do everything possible to forestall such a development and urges the individual members of this House to resist the further development of this harmful trend by acquainting the membership in their various communities with the nearness of the parent organization and its earnest desire to help them in the solution of their daily problems.

REPORT OF JUDICIAL COUNCIL

Your committee notes that as a result of the discussions and pronouncements of the Judicial Council there has been a steady improvement in the methods by which medical service is made available to the public. It regrets, however, that much remains to be accomplished, and it believes that the time has arrived when we should insist on the strict enforcement of the Principles of Medical Ethics by all constituent societies for, as so well stated by the Council, the Principles of Medical Ethics is accepted as a guide in professional relations and intelligently and faithfully followed by a large majority of the profession. There are, however, some isolated instances in which this is not true. The delinquents comprise individuals, certain groups and a few institutions. Solicitation of patients, particularly in industrial practice, unfair competition by clinics and groups, and unethical and unlawful practice of medicine by hospitals, dispensaries, insurances and universities furnish outstanding examples.

The Council further states, "Public confidence in our avowed declarations for medical control over things medical cannot be successfully cultivated or maintained unless we exclude or remove from the ranks of our organized profession those who ignore our ethical code, especially as it applies to the true professional spirit in our relations with each and every patient." It will be recalled, the Council continues, that "last year the House of Delegates amended its Principles of Medical Ethics so clearly that there can be no misunderstanding of the conditions mentioned but the present method of procedure of preferring charges makes the pronouncement ineffective." Your committee, therefore, deems it advisable to extend the origination of charges, in certain situations manifestly too great for county societies to handle, to the state association and possibly in rare instances to the national organization. Your committee agrees with the Judicial Council that, when the House of Delegates sees fit to extend such jurisdiction in matters of discipline, the Council should have the duties and powers then enjoined on it but should not at any time be expected to function in an *ex parte* capacity.

The Judicial Council again reminds us that medical ethics follow every member of the American Medical Association, whether in hospitals, in universities, in clinics or in private practice.

tice. While the member is at all times subject to the ethics of the profession, the hospital, university or clinic, as an entity, is not. Through the Council on Medical Education and Hospitals, in cooperation with the Judicial Council, sufficient oversight, persuasion and, if needed, pressure can be brought to accomplish that which the physicians in such institutions, as individuals, cannot. With such concerted action between the two Councils and with such enforcing legislation as has been suggested, many harmful and obnoxious practices would cease and others, not now presenting any large problem, would be prevented.

Your committee, therefore, recommends that the Council on Medical Education and Hospitals, together with the Judicial Council, formulate a plan whereby all those associated in the delivery of medical service be included in the investigation of hospitals for classification and that approval be based in the future on the ethical practices of the institution as well as on its scientific work.

Your committee further recommends that, in order to remove the menace which the Judicial Council reveals with respect to overlapping membership in state associations, the Constitution and By-Laws be so amended as to remove any further difficulty in assigning a member to the state in which he practices.

Finally, your committee records its disapproval of any plan of organization of the profession in the United States that permits a member to hold affiliation with the Association in more than one state.

In order to effectuate the suggestions contained in this report, your committee requests the Judicial Council to submit amendments to the Constitution and By-Laws of the Association as are necessary to secure the purposes sought.

Respectfully submitted

ARTHUR J BEDELL, Chairman.
J GURNEY TAYLOR.
BEN R MCCLELLAN
JOHN W BURNS
C. W ROBERTS

On request of the Vice Speaker, the House by a rising vote extended sympathy to the Speaker, Dr F C. Warnshuis, because of the death of his son.

On motions, duly seconded and carried, the report of the Reference Committee on Reports of Officers was adopted section by section and as a whole.

The Speaker referred to the Reference Committee on Amendments to the Constitution and By-Laws the section of the report requesting an amendment to the Constitution and By-Laws, and referred to the Judicial Council the last recommendation in the report of the Reference Committee on Reports of Officers.

Resolution on Organization of a Committee on Medicolegal Blood Grouping Tests

Dr J Richard Kevin, New York, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations

Resolved That a committee, to be known as the Committee on Medico-legal Blood Grouping Tests, be organized for the purpose of acquainting the suitable authorities in the legal profession with the existence and reliability of the blood grouping tests so that statutes may be enacted authorizing courts to order individuals to submit to blood grouping tests when they are required in those jurisdictions in which blood tests are not obligatory at present.

Resolution Requesting the Proper Authorities in the War Department to Distribute Hygeia in the CCC Camps

Dr Ralph A Fenton, Oregon, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business

Whereas The Civilian Conservation Corps in its various camps throughout this country is supplied with books and periodical literature by the War Department and

Whereas Such literature should promote the dissemination of approved health information be it

Resolved That the Director of the Civilian Conservation Corps and the Surgeon General and other competent authority in the War Department be requested by this House of Delegates to contract for the supply of the magazine *HYGEIA* to each CCC Camp excluding any other so-called health magazine published by private interests for profit.

The House recessed at 11 15 a. m. and was called to order by the Speaker at 11 40 a. m.

Report of the Judicial Council

Dr George Edward Follansbee, Chairman, presented the following report of the Judicial Council acting as a reference committee

A resolution was reported to the Judicial Council as a reference committee without action by the House. It reads as follows

'Under the standing rules of the House of Delegates, page 53 of the Constitution and By-Laws, a section entitled Solicitation of Votes, adopted by the House of Delegates at Saratoga Springs, N Y, June 13, 1902, reads as follows *Resolved* That it is the sense of the House of Delegates of the American Medical Association that the solicitation of votes for office is not in keeping with the dignity of the medical profession nor in harmony with the spirit of this Association, and that such solicitation shall be considered a disqualification for election to any office in the gift of the Association.'

The reference of this resolution to the Judicial Council without action of approval by the House places the Council either in the position of acting only as a reference committee reporting back to the House approval or disapproval of the resolution, or in the position of assuming that the action of the House would approve the request for opinion asked in the resolution and submitting it forthwith.

The Judicial Council cannot presume to anticipate what the action of the House of Delegates may be on any subject, therefore, acting only as a reference committee, it recommends the adoption of the resolution as written.

However, if the House approves the recommendation of the Judicial Council as a reference committee and adopts its report, the subject matter of the resolution is very important and the occasion for offering the resolution appears to be urgent. Therefore, the Judicial Council is prepared to offer its opinion as requested in the resolution at the pleasure of the House.

Respectfully submitted

GEORGE EDWARD FOLLANSBEE, Chairman

Dr Follansbee moved that the report of the Judicial Council as a reference committee be adopted. The motion was seconded by Dr Arthur J Bedell, New York, and carried, after discussion by Dr Isaac A Abt, Section on Pediatrics.

Dr Follansbee then presented the report of the Judicial Council on the resolution concerning solicitation of votes.

This resolution asks the decision of the Judicial Council on a standing rule adopted by the House of Delegates in 1902, in respect to solicitation of votes, in which it is declared "that it is the sense of the House of Delegates of the American Medical Association that the solicitation of votes for office is not in keeping with the dignity of the medical profession nor in harmony with the spirit of this Association, and that such solicitation shall be considered a disqualification for election to any office in the gift of the Association." Two questions are asked (1) 'whether said section of the Standing Rules is still in force' and (2) "whether any person who is elected or nominated in violation of said rules is legally eligible for nomination or election to an office in the American Medical Association."

To the first question the answer is that this Standing Rule, adopted in 1902, has never been repealed and is in the same force and effect as it has been since its adoption.

In answering the second question, a number of factors must be considered. In amending the Constitution by addition or change, a period of one year must elapse between proposal and adoption. Amendments to the By-Laws must be held over for one day. Both require a two-thirds vote. A Standing Rule requires no delay and only a majority vote. The obvious difference in importance in the three sections of laws governing our organization is indicated by the size of majority required for adoption and the variation between them in the amount of time required to provide thoughtful consideration of the subject matter.

There are qualifications for general officers incorporated in the By-Laws chapter IV, section 2, in which it is stated "The General Officers must have been members of the Association and Fellows of the Scientific Assembly for at least two years next preceding their election." The Standing Rule under consideration imposes another qualification, viz., that "Solicitation shall be considered a disqualification." It would be at least

strange legislation to divide the qualifications for general officers between two such widely diverse sections of our law as the By-Laws and the Standing Rules of the House of Delegates. It is apparent to the Council that the Standing Rule in question was adopted at a time and under the spur of a provocative occasion when emotion superseded reason and when hasty and incomplete legislation was more soothing to the House than effective in carrying out its purpose. That the rule is loosely drawn is evident in the absence of definition of the offense, solicitation constituting disqualification. It simply says "solicitation shall be considered a disqualification." Solicitation by whom, the candidate or by his friends? How, by word of mouth, by letter to personal friends, by general circularization, by a friend of the candidate asking the support of his friend, or by trading of votes between groups? There is solicitation and solicitation some dignified, fair and entirely proper, some reprehensible and beneath the dignity of this national organization of highly educated cultured professional men whose Principles of Medical Ethics is higher than that of any other profession unless it be the ministry. It is a shame on our organization that there is ever an apparent need for such legislation.

The Council is further of the opinion that in practice the rule is unenforceable. It has, however, been a strong and, at times, an effective moral influence. It has been among our laws for thirty-three years and has never been called on to function, although it is well known, at least to the older members of the House, that violations have not been rare. Disqualification under this rule might be punishment for an offense committed not by the candidate but by overenthusiastic friends and even against his wishes and order. It is common law that no one can be punished for an act of which he had no knowledge or to which he was not a party. It is further common law that no one should be punished without an opportunity to defend himself in a fair trial. The element of time would make this procedure impossible in practice.

For the reasons detailed, the Judicial Council considers the Standing Rule on "Solicitation of Votes" to be illegal and of no force and effect. This being so, there can be no violation. There being no violation, the supposed person mentioned in the resolution is legally eligible for nomination or election. The Judicial Council believes that, if the House desires to have our laws disqualify for nomination on a basis of reprehensible solicitation, adequate legislation and phraseology can be found.

Respectfully submitted

GEORGE EDWARD FOLLANSBEE, Chairman

It was moved by Dr Isaac A. Abt, Section on Pediatrics that the report of the Judicial Council on the resolution on solicitation of votes be adopted. The motion was seconded by Dr H. B. Everett, Tennessee, and carried, after discussion by Dr William D. Chapman, Illinois.

Resolutions Protesting Federal Economics Harmful to Our National Defense

Dr Arthur J. Bedell, New York, read the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

WHEREAS It was thoroughly demonstrated during the World War that this country paid highly in blood and money because there was no adequate mechanism for speedy mobilization and training defensive forces of the nation and

WHEREAS The Medical Department of the United States Army was in no noteworthy better condition than other departments despite the fact that it must always be mobilized before combat and before other arms are mobilized and

WHEREAS Under authority of the National Defense Act since the World War the Medical Department of the Army has been maintaining Reserve Officer Training Corps Units in medical schools which supplied about one half of the new medical reserve personnel and gave valuable training preparatory to any national emergency but which have now been discontinued by act of Congress ostensibly as an economy measure leaving the War Department greatly embarrassed in the procurement of new medical officer personnel which embarrassment will increase to serious proportions after a very few years therefore be it

Resolved That the Medical Society of the State of New York protest federal economics harmful to our national defense and be it further

Resolved That the Medical Reserve Officers Training Corps Unit should be reestablished as soon as possible and be it further

Resolved That a copy of these resolutions be forwarded to the War Department the Surgeon General of the United States Army the Federal Congressmen from the state of New York and the American Medical Association

Remarks by Dr C. E. Mongan

Dr C. E. Mongan, Massachusetts, addressed the House as follows:

I think I might be derelict in my duty not only to my local county society but to this great body and its executive officers if I didn't tell you a very pleasant incident that happened during our campaign in Massachusetts with regard to furnishing adequate medical care to the citizens.

I requested the director of the economic division of this organization to send to Massachusetts all the literature relating to social insurance and medical economics. I asked for 300 sets. Inside of one week this organization placed at our headquarters 300 sets on social insurance. Those pamphlets—I think there are ten in all—you are all familiar with. I think such cooperation and such efficiency should not go unnoticed by our organization. I have no resolution to offer. I simply want to call your attention to the efficiency and the cooperation of your parent organization. More than that, it had a wonderful effect on every man who received one of those packages. One man came to me and said, "I have criticized the American Medical Association for not doing this. I wish to withdraw it."

I know that the American Medical Association executives are perfectly willing to do that for every man here. I hope that you will take advantage of this cooperation. It has a psychological effect that is inestimable on the rank and file of your organization.

Address of Dr George H. Simmons

The Speaker introduced Dr George H. Simmons, who addressed the House as follows:

Mr. Speaker and Gentlemen, Members of the House of Delegates: I came here not to talk but to listen. I must say that I thank you very much for your reception of me. I wish I realized that I deserve it. I couldn't help thinking of the interim between the time I was active in the deliberations of this body and now. That was thirty-five years ago, the first time the Association ever met at Atlantic City. We had so many receptions, we were so well taken care of, that we came back in two years and again in two more years. It looked as though we were going to make a biennial visit.

Those occasions are remembered by me very well because of two incidents or conditions. One was that the year before in February I had been elected Editor and Manager of *THE JOURNAL* and that at the previous meeting they made me Secretary, so I came to Atlantic City at the first meeting here with a good deal of trepidation and doubt as to what I was going to do and how I was going to do it. I know I worried a good deal, but everything went off all right, as it always does and your worry is temporary anyway.

The other incident was the fact that at that meeting a resolution was adopted creating a committee on reorganization. As the result of the appointment of that committee, the House of Delegates was created at the next meeting.

It has been a delight to go from then to now and see what the Association is doing, continually spreading out its good work. Could that have happened if that reorganization had not made this American Medical Association an organization representing the profession of the whole country and by the creation of this House of Delegates? I don't know.

It is well to look back over these things of the past, and it is a pleasure to see how the Association has gone through the depression. I want to congratulate the Board of Trustees and the officers of the Association in having weathered the storm and having made the best financial report ever made in the history of the Association.

Introduction and Addresses of Officers of Canadian Medical Association

The representatives of the Canadian Medical Association were escorted to the rostrum by the sergeant-at-arms.

The Speaker presented Dr J. C. Meakins, president of the Canadian Medical Association, who addressed the House.

Mr. Speaker, Members of the House of Delegates of the American Medical Association: It is hardly a year since we received in Calgary at our own annual meeting an invitation from you to hold a combined meeting in Atlantic City this week. I cannot tell you with what pride and honor and pleasure that

invitation was received with whole-hearted enthusiasm by our association.

Just the other day I think I was telling your President-Elect, Dr McLester, how in going over the ancient records of the early medical societies of Canada I found in a musty, yellow, old minute book certain resolutions and extracts from correspondence which had taken place between the Medical Society of Upper Canada and the Medical Society of Lower Canada, and the embryonic organization of the American Medical Association. That, I believe, if my memory serves me correctly, was in 1848. I think it might have been two years before your association was sufficiently founded. In the extracts of those minutes there was proposed and being explored the possibility of forming an American Medical Association which would include not only the state associations I presume they were then, but the provincial associations of Canada. For certain reasons this could not be brought about, and the proposed combined meeting was to take place in 1848 and was postponed for eighty seven years.

Now today on behalf of myself and our association, we have great pride and we appreciate the honor that you do us in permitting us to appear before you on the rostrum of your House of Delegates, and I bring from our council a resolution, which unanimously passed yesterday by standing vote, to invite you to be our guests in a combined meeting to be held in Canada in the near future. The resolution says before 1940. We would like to leave the date open so there would be no *anno Domini* interfering in any way with your accepting our invitation.

I take great pleasure in laying this invitation before you today. I thank you.

The Speaker then presented the chairman of the Council of the Canadian Medical Association, Dr George S Young, who addressed the House as follows:

Mr Speaker, Members of the House of Delegates. I take it that in front of me is the workshop of the American Medical Association and that you are the workmen, and that for the time being you have stepped down from the heights of scientific activity and are doing the drudgery work for the American Medical Association.

As a member of a similar organization which has a workshop on a smaller scale, I can keenly appreciate your difficulties and the magnitude of your work and I want to express my very keen appreciation of the invitation that was extended to me to come here today and to see you in your workshop. I am delighted indeed that that opportunity has been afforded me, and once more I want to express my appreciation for the invitation.

The Speaker presented the past president of the Canadian Medical Association, Dr J S McEachern, who addressed the House as follows:

Mr Speaker and Members of the House of Delegates. It seems rather an anomaly that immediately after I considered myself defunct I should be resurrected and exhibited as past president. I will not delay you except to extend to you our hearty good wishes for a successful meeting and to thank you for your great kindness in honoring me with an invitation to be present here.

The Speaker presented Dr Alexander Primrose, chairman of the Program Committee of the Canadian Medical Association, who addressed the House as follows:

Mr Speaker and Members of the House of Delegates. It is a very great pleasure for me to appear here today. I may say that a few years ago you did me the honor of electing me an Honorary Fellow of the American Medical Association. Therefore I can speak from that standpoint as well as past president of the Canadian Medical Association. I share the honors of Dr McEachern in that respect.

As a fact, we Canadians have appreciated for many years the relationship which has existed in medicine between Canada and the United States. Many of us in Canada are fellows of special societies in the United States and in that way we cooperate. Occasionally we have had these special societies meeting in Canada. As an instance, last summer we had the privilege of entertaining the American Surgical Association in Toronto. Now we hope that that has extended to the general profession in that the Canadian Medical Association and the

American Medical Association may repeat what is occurring at the present moment, and it is a great pleasure and privilege to be here at this initiation of combined meeting. I hope it is only one of many in the future, because I feel that the more we cooperate in the profession of medicine on this continent the better it is for the profession generally and also for the public, because in so doing we have an influence and a power over the community which we could not otherwise exert. I therefore in these few words express my great personal pleasure in being present here today.

The Speaker presented Dr T C Routley, the secretary of the Canadian Medical Association, who addressed the House:

Mr Speaker, the Members of the House of Delegates of the American Medical Association. I indeed count it a great privilege to associate myself with my colleagues in saying how deeply we appreciate the honor you have done us in asking us to meet with you in your country and in asking us to appear before you this morning in order that we might say to you face to face what is in our hearts, as has been said by the four previous speakers, namely, we are grateful that you in your wisdom saw fit to allow these nations, one so large the other so small, and yet with ideals which are always in harmony, to meet together.

I well recall some twelve years ago when it was my privilege to be the official fraternal delegate from Canada to your meeting in San Francisco, throwing out the suggestion that some day we might meet together. Twelve years—quite a long piece to look forward not so long to look back—and we are together.

Perhaps you will be interested in knowing that we moved our organization down here lock, stock and barrel. We have an attendance in our council of seventy-six out of one hundred and twenty-odd, which we consider an exceptionally splendid turnout.

Then perhaps, Mr Speaker, one of the most interesting observations I might make is this, that while meeting for the first time outside of our own country in a foreign land we completely revised our constitution and by-laws. I do not desire to appear to be boastful, but if you can find a better demonstration of international good will than that I would like to have it displayed.

I do trust, sir, that the invitation extended to you by our president, coming as it does, from the hearts of the Canadian people as well as the Canadian physicians, will cause you to find it possible in the not far distant future to accept that invitation and give us the pleasure of endeavoring to show you the best we can our appreciation of your hospitality extended to us on this occasion.

Response of Officers of American Medical Association

The Speaker called on Dr Walter L Bierring, President of the American Medical Association, who responded as follows:

Mr President, Mr Chairman of the Council, Officers of the Canadian Medical Association, and Fellow Delegates. I know that I speak for you when I express the appreciation of this body for this courteous visit, for this cordial invitation, and for this further manifestation of the unity of interest, symbolized as it is, by our many efforts together in the extension of English medicine throughout the new world. We feel that we have always been a family scientifically and fraternally and that from now on there shall be a still closer bond between these two nations, divided as they are by an invisible boundary line, common in their interests for the furtherance of scientific medicine and human welfare and we trust, too, that we may again join hands across the border in their Canadian city. We feel assured that warmth of hospitality which has ever been characteristic of our Canadian colleagues, will come to us then in fullest measure.

The Speaker called on Dr J S McLester, President-Elect of the American Medical Association, who spoke as follows: I want to read a telegram that I know will give you the same pleasure that it gave me.

The British Medical Association sends cordial greetings to the American and Canadian Medical Associations on occasion of first joint congress and best wishes for successful meeting.

ANDERSON

The House recessed at 12 30 p m, to reconvene at 2 30

Tuesday Afternoon, June 11

The House of Delegates was called to order at 2 30 p m by the Speaker, Dr F C Warnshuis

Report of the Reference Committee on Reports of Board of Trustees and Secretary

Dr H H Shoulders, Chairman, presented the following report

REPORT OF THE BOARD OF TRUSTEES

Your committee proceeded as follows in its consideration of the matters referred. Those who desired to offer criticism were given an opportunity to do so. No delegate appeared to offer criticism. Secondly, your committee requested officers and bureau heads to appear before the committee in order that they might increase our understanding of the various activities touched on in the report. Your committee found that the Board of Trustees had been unusually active during the past year. It held five meetings, which lasted from two to three days each, and the Executive Committee of the Board met at least once each month, except when there was a regular meeting of the Board. This fact was brought out in the hearings and your committee desired to transmit this finding to you as an indication of the thoughtfulness with which the membership of the Board has approached its responsibilities.

Your committee notes with satisfaction the financial position of the Association as portrayed by the report. This is an exceptional showing for an organization such as ours after some five years of depression.

The publications of the Association are in such form that each is made to serve a definite purpose. The slight financial loss experienced in the publication of some is warranted, in the opinion of your committee, by the benefits derived.

These publications have grown in popularity and usefulness. This progress is due to the sound policies followed, the energies exerted and the intelligence applied to them. The services they render cannot be appraised adequately. Your committee expresses a confidence in the cautious wisdom of the Board in the matter of taking on additional publications that might involve a financial loss without an increasing general benefit to the profession.

Your committee notes with satisfaction the increasing use of the Package Library Department maintained for the benefit of the membership. It is suggested that the delegates present take occasion to inform their constituents of the advantages offered by this service particularly to those members who do not reside in the neighborhood of an extensive medical library.

Your committee requested various executives to come before it for the purpose of increasing understanding of the matters touched on in the report. The following persons appeared: Dr J H J Upham, Chairman of the Board of Trustees, Dr Rock Sleyster, Dr Olin West, Dr Morris Fishbein, Editor of THE JOURNAL, Dr Paul Nicholas Leech, Secretary of the Council on Pharmacy and Chemistry, Dr R G Leland, Director of the Bureau of Medical Economics, Dr W W Bauer, Director of the Bureau of Health and Public Instruction, and Dr W C Woodward, Director of the Bureau of Legal Medicine and Legislation. Much was brought out in the discussions that took place by the members of the committee and heads of the departments. Dr Arthur J Cramp, Director of the Bureau of Investigation, was ill and could not appear.

Each of these officers seemed anxious and cooperative in his efforts to portray to the House the particular services being rendered the Association. The membership of your committee was impressed by the ability and sincerity of these men. Your committee found much evidence of the genius that has molded all these different activities into one coordinated, harmonious activity. For example, your committee found the Bureau of Health and Public Instruction giving aid to the Bureau of Legal Medicine and Legislation and vice versa.

Your committee wishes to commend the Board of Trustees on the care with which it has selected the personnel that heads the bureaus. Your committee would like to discuss many of the facts developed in the hearing, but time will not permit.

Council on Pharmacy and Chemistry. Your committee will mention particularly the activities of the Council on Pharmacy

and Chemistry. The secretary of this council reports to us that the membership of the Council, which serves without compensation, devotes many hours each week to the work of the council. Your committee is impressed with the thoroughness with which this department carries on its activities. This is evidenced also by the fact that commercial concerns and quacks have not challenged the accuracy and thoroughness of the work of this council with success before any court of the land. This is a remarkable record when the activities of this council are challenged on every side. This council has been in existence for about thirty years, its prestige with the public, we believe, is growing, the good it has accomplished for the profession and the public cannot be appraised. Your committee wishes to commend the members of the council on the self-sacrificing spirit and thoroughness that characterized their activities.

Bureau of Medical Economics. This portion of the report of the Board of Trustees was referred to the Reference Committee on Medical Economics for consideration.

Bureau of Legal Medicine and Legislation. It is obvious to every delegate that the activities of this bureau could not be covered in any brief report, nor would your committee adopt such a task. Your committee would rather commend the activities of the bureau and the tireless energies with which it has served and is serving the profession in the trying legislative period through which we are passing.

Bureau of Health and Public Instruction. Dr W W Bauer appeared before the committee to elaborate on the report of the Board of Trustees dealing with this bureau. Your committee finds that this bureau has exerted a most wholesome influence in the formation of the policies followed by various lay organizations, such as women's clubs and parent-teacher organizations. Officers of state organizations are to a degree familiar with the fact that socialistic groups have sought the political influence of various women's organizations in the promotion of their ends and purposes. Some of these women's organizations are particularly vulnerable to the approach of the socialistic groups and are unable to make a critical analysis of the matter they are requested to endorse or sponsor. Your committee finds that this bureau has been most helpful in the matter of influencing the course taken by many of the lay groups, with the result that they have become more cautious. Members of this bureau have been placed on important policy forming committees of the National Federation of Women's Clubs. It is suggested that delegates recommend to their state committees on public policy and legislation that they seek the advice of this bureau on all matters touching on the public health policies of state associations and in the matter of dealing with lay groups, and that the component units of state associations use this source of guidance and information in their dealing with local lay organizations in matters affecting the public health.

Your committee would like to emphasize the fact that through out the hearings it was impressed with the cooperative spirit that is displayed between the various bureaus of the Association. This serves to emphasize the wisdom of conducting all these activities directly under the supervision of the Board of Trustees, which enables the Board of Trustees to coordinate policies and activities in such a way as to accomplish the most beneficial results for the profession as a whole. It gives the Board freedom in the selection of a personnel whose congeniality permits of such cooperative endeavor.

It becomes apparent that time is required for a person, however capable, to acquire a familiarity with the duties to be performed in one of these bureaus or councils. It was made to appear that the Board has given consideration to the matter of selecting understudies who at the proper time will be adequately fitted to take over the duties and responsibilities of these various officers. Your committee commends this action on the part of the Board.

Concerning the action of the Board on the question of liability insurance for members. It approves this decision and action on the part of the Board.

In conclusion, your committee would venture to suggest that reference committees in the future call before them the various bureau heads as well as representatives of the Board of Trustees. It believes that such action would reveal much that would stimulate a higher appreciation and respect for the many duties that are carried on at the headquarters office.

REPORT OF SECRETARY

Your committee found much in the report of the Secretary that merits commendation. It is noted that the membership of the association has increased by more than 1,500 and that the Fellowship has increased.

It is also noted that the activities of the headquarters office in contacting component societies throughout the country has increased materially. Your committee feels that this is an important activity and that it might be further increased with beneficial results in the promotion of the uniformity of our activities throughout the various component units and the promotion of a more cordial understanding and sympathy.

The Annual Conference of Secretaries, however beneficial and helpful does not suffice to bring the heads of various departments of our national organization before the membership at large in the various states. It is recommended that the delegates present recommend to their constituents that they increasingly use members of the headquarters office on their state programs and in their various committee activities.

Your committee notes with satisfaction a statement by the Secretary to the effect that marked progress has been made during the past year in increasing the efficiency of medical organization throughout the land.

There is embodied in the report of the Secretary a brief statement of the proceedings of the extraordinary session of the House of Delegates. Your committee desires to give added emphasis, if possible, to the importance of this particular report. It should serve to emphasize that organized medicine presents a united front and that critics within our membership constitute an almost infinitesimal proportion of the whole.

Respectfully submitted H. H. SHOULDERS, Chairman

HENRY C. MACATEE.

E. F. COBURN

B. T. KING

FRED MOORE.

On motion of Dr. Shoulders, seconded by Dr. H. B. Everett, Tennessee, and carried, the portion of the report dealing with the report of the Board of Trustees was adopted.

Dr. Shoulders moved that the section of the report referring to the report of the Secretary be adopted. The motion was seconded by Dr. Ralph A. Fenton, Oregon, and carried.

It was moved by Dr. Shoulders, seconded by Dr. Arthur J. Bedell, New York, and carried, that the report be adopted as a whole.

Executive Session—Tuesday Afternoon, June 11

The Speaker ruled that officers of state organizations and members of county societies and of committees of state organizations, vouched for by their state delegates, would be permitted to remain for the Executive Session of the House.

The Sergeant-at-Arms polled the House, and on motion of Dr. H. B. Everett, Tennessee, seconded by Dr. C. S. Gorsline, Michigan, and carried, the House went into executive session at 1:45 p. m., with the Speaker, Dr. F. C. Warnshuis, in the Chair.

Report of the Special Reference Committee

Dr. Edward R. Cuncliffe, Chairman, presented the following report:

The Special Committee appointed to consider all resolutions concerning the control of reproduction begs leave to report that, after a careful study of these resolutions, it recommends that not any of them be approved as introduced. The committee desires to present as a substitute resolution the following, with this preamble: That the House of Delegates declares that nothing in the following resolutions be interpreted as a declaration or action either for or against birth control:

WHEREAS, Under the stimulus of large nonmedical groups the general use of contraceptives is being advocated and encouraged despite the existing law not only by the above mentioned groups but by commercial interests as well; and

WHEREAS, The ultimate effect of these measures on the health and general welfare of the population of the United States is unknown if not questionable and should accurately and extensively be studied by the medical profession in whose care the health of the people rests; and

WHEREAS, The laws both federal and local governing the physicians in their advice to individual patients where such advice is given as a thera-

peutic measure seem to be complicated, not well understood, and generally unsatisfactory and their interpretation difficult, therefore be it

Resolved, That a special committee be appointed after due consideration by the Board of Trustees to study these related problems and to present at least a preliminary report to the House of Delegates of the American Medical Association at the 1936 annual session and be it further

Resolved, That the trustees be requested to appropriate the funds necessary in order to carry out the purposes of these resolutions.

Respectfully submitted

E. R. CUNCLIFFE, Chairman

T. HENSHAW KELLY

J. ALLEN JACKSON

E. H. CARY

ALFRED A. WALKER

The report of the Special Reference Committee was adopted on motion of Dr. Cuncliffe, seconded by Dr. George W. Kosmak, New York, and carried, after discussion by Dr. G. Henry Mundt, Illinois.

Report of Reference Committee on Medical Economics

Dr. W. F. Braasch, Chairman, presented the following report:

1. Relative to the resolutions introduced by the Medical Society of the District of Columbia.

(a) Resolution on Medical Service Organizations. Your committee feels that no plan for the solution of the problems involved in this resolution has been perfected to such a degree that the American Medical Association would be justified in sponsoring it. Further, your committee recognizes the impracticability of sponsoring any specific plan but approves the establishment of principles governing such plans. The Bureau of Medical Economics has at its disposal most of the plans proposed by the various organizations and stands ready and willing to furnish these on request to any component county or state unit or any individual member thereof. In view of this fact, your committee deems it inadvisable for the American Medical Association to attempt to dictate any form or set-up for medical service but assures the members that the parent organization is always willing to advise and cooperate with any unit desiring assistance. Likewise, your committee would hesitate to recommend to the Board of Trustees an expenditure of a definite sum of money for such purposes as suggested in the resolution because of obvious reasons, among them being the impossibility of estimating the cost. Your committee recommends that this resolution be not passed.

(b) Resolution on Preparation of a Statement Regarding Medical Service Experiments. Your committee also realizes the inadvisability of the publication of incomplete experiments in medical service which might be presented to the President of the United States as recommended in this resolution. Your committee recommends that this resolution be not passed.

(c) Resolution on Care of the Indigent. In this resolution problems are raised which are similar to those involved in the other resolutions and the impracticability of their execution is quite evident. Your committee would recommend that this resolution be not passed.

2. Your committee believes that the survey made of the work done by the Bureau of Medical Economics during the past year is worthy of the highest commendation. It shows the wide scope of the bureau's activities and the immense amount of excellent work that it is doing. It endorses in detail the various suggestions and recommendations that the survey contains.

Your committee notes with approval that the demand for accurate information on sickness insurance and allied problems is being met by publication of articles in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* and in pamphlets. It would also commend the articles on sickness insurance and allied subjects that are published in *HYGEIA* for the benefit of the laity and would suggest that they appear more frequently. It would also be desirable that messages of a similar nature be more frequently transmitted over the radio. Your committee would recommend that articles on health insurance be sent to newspapers which would publish them. It would also be desirable that material accumulated by the bureau be furnished to editors of state medical journals in order that they may make this material more available to the readers of these publications.

Your committee would encourage every member of the profession to become more interested in the various problems of medical economics and to take advantage of the unlimited

sources of information at the disposal of the Bureau of Medical Economics

Your committee notes with approval the efforts made by the bureau in making available unbiased data published in the "Handbook on Sickness Insurance" which serve as a guide to debates, theses and addresses such as are carried on by high school and college students on the subject of state medicine, sickness insurance and allied subjects. In view of evident propaganda of a radical nature which is carried on in some schools, increased efforts should be made to disseminate accurate information.

Your committee commends with special emphasis the stand taken by the bureau with regard to group hospitalization. It is convinced that the natural development of such schemes would lead sooner or later to an inclusion of medical service in one form or another with inevitable deterioration in the quality of service. It is quite in agreement with the statement that there is grave doubt that any plan of group hospitalization is using an actuarially sound base for premium rates.

Your committee commends many of the efforts made by local county units to solve problems involved in the care of individuals in the low income group. It would voice its approval of the sentiments expressed at the special session of the House of Delegates in February 1935 in commending these efforts. It also notes with approval the careful survey made by the bureau of the various medical service experiments carried on by the different communities. It would recommend that even greater use be made of the parent organization's presentation of available material on which to base future plans.

Your committee would commend the Bureau of Medical Economics for the interest it has shown in the various problems concerning life, health, accident, casualty and malpractice insurance. It trusts that the bureau will continue its investigations.

Your committee approves the careful study made by the bureau of all available information in regard to relief measures for the indigent sick which is assembled in the report entitled "Care of the Indigent Sick," published last December, and it recommends its use for reference.

In reviewing the ten principles governing the practice of medicine that were adopted by the House of Delegates at the session in Cleveland in 1934, your committee finds that some confusion has arisen in regard to principle 6, which reads as follows:

However the cost of medical service may be distributed the immediate cost should be borne by the patient if able to pay at the time the service is rendered.

Your committee recommends that principle 6 be changed so as to read as follows:

In whatever way the cost of medical service may be distributed it should be paid for by the patient in accordance with his income status and in a manner that is mutually satisfactory.

Your committee recommends the excellent study of the distribution of physicians made by the bureau, which excels in every respect any survey previously made and should be endorsed as a reference for investigation of this subject.

Your committee recommends the thorough survey that has been made of the fee schedules of several hundred county medical societies. The material accumulated should be of great value to any one interested in this subject. In view of the impossibility of standardization of fee schedules, which are necessarily variable and of a temporary nature, it is evident that no standard schedule of fees can be established and maintained by any medical organization.

Your committee approves the timely study that is being made by the Bureau of Medical Economics on the subject of health services in colleges and universities. When completed this promises to be of great interest and practical value, and your committee would commend its speedy completion.

Although your committee appreciates the value of the publication of the work of the bureau in the monthly bulletins and in pamphlets, it nevertheless believes that much of this valuable material is lost to the average practitioner because of its volume. It seems to your committee that it would be highly desirable if the essence of the articles were transcribed in some form so that they could be easily assimilated by the average medical reader. Material accumulated by the bureau

should be published in such a manner that it will attract the attention of the casual reader and be easily appreciated.

3 In reviewing that portion of the report of the Bureau of Legal Medicine and Legislation, as printed in the Handbook, dealing with subjects of economic interest, your committee notes with interest the development of the federal health insurance bill. Of particular interest is the fact that the name of the proposed "Social Insurance Board" has been changed to "Social Security Board" and that no duty is now devolved on the board to study or make recommendations with respect to health insurance. The board, however, is at liberty to make such an investigation regarding social insurance under its general commissions.

Under the subject of state health insurance, your committee notes that of the various bills proposed in the various state legislatures for health insurance, including the Epstein bill and bills of similar nature, there is no state in which such health insurance bills have been enacted.

Your committee has read with interest the resumé of the various provisions made by the Federal Emergency Relief Administration and it notes with alarm the unlimited number of persons who are entitled by law to relief under the United States Employees' Compensation Commission. The situation, however, is somewhat mitigated by the fact that persons employed under this act will not be entitled to all the benefits available to regular employees of the federal government but will receive benefits including medical services only for traumatic injuries arising out of and in the course of their employment.

In closing your committee would again commend the great work done by the Bureau of Medical Economics but we would urge the desirability of developing methods by which that storehouse of data accumulated by the bureau be made more readily available and the approach more practical to every member of the medical profession and to each county unit as well as to the various state medical societies.

Respectfully submitted

GUY W. WELLS
FRED B. CLARKE

W. F. BRAASCH, Chairman
HENRY A. LUCE
CHARLES J. WHALEN

On motions, duly seconded and carried, the report of the Reference Committee on Medical Economics was adopted section by section and as a whole.

On request of Dr. C. E. Mongan, Massachusetts, for information concerning the situation in California with respect to health insurance, Dr. William R. Molony Sr., California, called on Dr. T. Henshaw Kelly, California, who addressed the House.

Report of Committee on Legislative Activities

Dr. E. H. Cary, Chairman, presented the following report which on motions of Dr. Cary, duly seconded and carried, was adopted by sections and as a whole.

Mr. Speaker, Members of the House of Delegates

Your Committee on Legislative Activities begs, first, to commend the wisdom of the Board of Trustees and this honorable body in adding to the original committee Dr. R. L. Sensenich. His appointment followed the adoption of the resolution that it would be wise to make more definite contact with certain groups. Just how far the committee could go in this direction was not known, but it had always been the policy of the Committee on Legislative Activities, as constructed, to make important contacts with leaders of other groups, particularly those concerned with legislative affairs. It was decided within the committee that the new member should contact leaders of various organized groups in industry, education and labor and at frequent intervals communicate with the various state secretaries to assist in organizing a broad and direct approach to the lay public in opposition to harmful legislation. It was hoped in this manner to stimulate on the part of the leaders of the different state organizations a real sense of responsibility and the desire to cooperate in all legislative undertakings. A vast amount of this work has been done and undoubtedly much good has been accomplished.

At the Cleveland session your committee reported that a spirit of friendliness and cooperation had been developed between the

leaders of the American Legion and the American Medical Association. Reference was made to the significance of the Reed bill, which continued the four point program of the American Legion. The point of special interest to the medical profession was section two which opened the way for hospitalization benefits to World War Veterans without service connected disabilities. Your attention was directed to an oath prescribed within the law, which related to the veteran's financial ability to take care of his own hospital needs, particular emphasis was laid on the great import of this one point. Your committee is happy to state that leaders of the American Legion and the administrator in charge of veterans' affairs have recognized the importance of this oath.

Section 29 of Public Law Numbered 141, Seventy-Third Congress, which amended section 6 of Public Law Numbered 2 as amended by Public Law Numbered 78, Seventy-Third Congress added the following proviso to the retained provision of section 6:

Provided That any veteran of any war who was not dishonorably discharged, suffering from disability disease or defect who is in need of hospitalization or domiciliary care and is unable to defray the necessary expenses therefor (including transportation to and from Veterans Administration facility) shall be furnished necessary hospitalization or domiciliary care (including transportation) in any Veterans Administration facility within the limitations existing in such facilities irrespective of whether the disability, disease or defect was due to service. The statement under oath of the applicant on such form as may be prescribed by the Administrator of Veterans Affairs shall be accepted as sufficient evidence of inability to defray necessary expense.

You will observe that there is no requirement as to which war or the length of service in connection with these applicants. This is a substantial liberalization of the benefits of domiciliary or hospital care. Section 29 makes it obligatory on the Veterans' Administration to accept the statement under oath of the applicant that he is unable to pay the necessary expenses, however, the provision has been duly supervised. Section 12 of Public Law Numbered 2, Seventy-Third Congress, provides a penalty (a fine of not more than \$5 000 00 or imprisonment for not more than two years, or both) for false statements made under oath.

One would think, because of the depression, that the demands of the veterans would have increased during the past year or two. Your committee found, however, while in Washington recently, that there were some 3,000 beds unused in the institutions for patients with tuberculosis, and some 6,000 beds in the hospitals devoted to general medical and surgical cases were not being used. It would seem that the oath, the regulations of the Veterans' Bureau, and the cooperation of the Legion itself, has definitely curtailed the demands for free hospital and medical care by those who are able to pay.

In the last annual report your committee made reference to a plan then effective in Illinois. There had been organized a medical commission, composed of district, county and post surgeons of the Illinois Department of the American Legion. This commission, as now constituted, acts as an advisory committee to the Rehabilitation Committee in the interests of ex-service men. It has been successful in improving this service and at the same time, has preserved the worth while ideals of the medical profession.

Drs C B Wright and F S Crockett of the committee were invited to be present at a conference of the Area D Rehabilitation Committee in Chicago last June. On this occasion Dr Crockett attended and initiated a conference between the American Medical Association and the American Legion. Later National Commander Hayes and certain of our leaders arranged for such a meeting, which was held in Chicago on Sept 7 1934. Drs Wright, Crockett, Woodward, Fishbein, Sensenich, West, Hayden and Cary were present on behalf of the American Medical Association. Commander Hayes, Messrs Cliff, Taylor Miller, and Drs Williamson and Fredrickson represented the Legion. The various possible beneficial channels of cooperation between the two organizations at interest were discussed at length. Your committee brings to you the major conclusions. For instance:

The contacts between the American Medical Association and the American Legion during the past two years were unanimously considered to have been of value, it was likewise thought that a feeling of confidence and understanding between the two groups had been developed.

Combined interest on medical and hospital matters should be maintained between the authorities of the two organizations.

The members of the Legion committee expressed pleasure that the American Medical Association had, at its Cleveland session, supported the idea of cooperation between the two groups.

It was agreed subject to the approval of the Legion National Convention, that each department rehabilitation committee or group should invite to its advisory membership two members of the state society pertinent to the American Medical Association.

When consideration leading toward possible requests for new hospital construction should arise, the matter was to be submitted to a committee of the Legion Rehabilitation group, which would include the medical advisory members, for recommendation before being acted on by a department convention. Under such circumstances it was also agreed to add temporarily to the canvassing committee one representative each from the American Hospital Association and the Veterans' Administration.

Another fundamental conclusion contemplated the continuance of the depression and a greater number of indigents. In this event, if waiting lists were increased and hospital facilities exhausted, the American Medical Association was to participate in seeking a solution satisfactory to the medical profession and to the American Legion.

The conferees reaffirmed a previously agreed on point that veterans suffering with tuberculosis or nervous and mental diseases, requiring hospital care, should be the responsibility of the national government in a federal institution.

Acute cases widely separated, in no instance were to constitute a legitimate demand for new hospitals. A far more economical and medically effective procedure could be adopted. For any emergency of a service connected character the disabled veteran would be taken care of irrespective of his location by merely gaining telephonic consent from the proper authorities in that particular district.

Several items, which required additional study because of some rather widespread misunderstandings, are enumerated here:

1 Acute service and non service connected cases in which added disablement or death is said to have occurred as a result of having to be transported from the places where the onset occurred, to governmental hospitals.

2 Number of cases in which veterans were ordered to government hospitals on recommendation of community physicians or other persons, and on examination found not to require treatment or operative procedure.

3 All procurable records and histories of instances in which acute cases did not receive treatment because of lack of appropriate local hospital facilities or because of inadequate funds or lack of tendency of community hospitals or physicians to extend care.

Your committee has stated only the important conclusions reached in the September conference.

Commander Hayes extended an invitation for representatives of the American Medical Association to be present at the Legion's annual meeting. Dr F S Crockett, member, and Dr E H Cary Chairman, of the Committee on Legislative Activities, were directed by the Board of Trustees to attend this convention of the American Legion, which was held in Miami Fla., Oct 22-25, 1934.

On Nov 12, 1934 the Chairman of the Committee on Legislative Activities made an extensive report to the Board of Trustees regarding the reception given its representatives and the general attitude of the leaders of the Legion. The recommendations that resulted from the joint conference held Sept. 7, 1934, and referred to herein, were presented to the Rehabilitation Committee of the Legion and endorsed later being unanimously accepted by the general convention. There is presented for your consideration a summary of what has been done with the hope that you will express similar approval.

In the November report to the Board of Trustees, the members of your committee attempted to record their own reactions to the many personal contacts made while in Miami, many of which seemed extremely valuable, and when assured of the Legion's acceptance of the recommendations agreed on at the joint conference, they developed the thought that the work accomplished by the Rehabilitation Committee of the American Legion was a part of the present philosophy of the medical profession toward caring for the sick. It was suggested that

any form of sickness insurance, governmentally controlled, would tend to break down hospital and medical benefits already gained. Those leaders who had the interest of the veterans at heart could easily foresee the implications of this new menace to the practice of medicine as it had been developed in this country. The widespread adoption of any one of the several forms of sickness insurance, which had been advocated from many sources, would change the whole philosophy of medical practice, and undoubtedly the special benefits enjoyed by the veterans would be disturbed. At the conclusion of the visit to this convention of the Legion, it was felt that powerful allies had been gained.

The members of the Committee on Legislative Activities, fortunately also members of the House of Delegates, were present at the Special Called Session held in Chicago on February 15-16 this year. When the House finally concluded its work by unanimously accepting the Reference Committee's report, the Committee on Legislative Activities felt that the time was at hand when leaders of other interrelated medical organizations should accept as final the action taken by the House of Delegates—the value of unity within our profession not being underestimated.

The members of special societies are primarily members of the American Medical Association and, as far as we knew, had not been given an opportunity to express an opinion on legislative matters except through their county societies, which are the governing units of our national organization. Your committee recognized that the impression had been created in Washington that medical opinion was greatly divided on the subject of compulsory health insurance. In view of the action of the House of Delegates, it seemed that the responsible leaders of any group of medical men could acknowledge the action of the House and correct the impression that was being used as propaganda for new legislation affecting the medical profession. We who practice medicine realized that any endorsement of the idea of compulsory health insurance on the part of certain medical men represented personal views, for, as previously stated, the members of these special societies had not been given an opportunity therein to indicate their attitude. In this connection, your committee acknowledges with appreciation the high service rendered by the distinguished secretary of the American Academy of Ophthalmology and Otolaryngology, Dr. W. P. Wherry. He was able to arouse the interest of a very large group of our medical men who were also members of special societies, all of whom gave expression of their support of the stand taken by the honorable House of Delegates of the American Medical Association.

On April 26, 1935, Drs. Crockett, Sensenich and Cary of the Committee on Legislative Activities, joined by Dr. Woodward, spent several days in Washington, meeting many old friends and developing new ones.

Methodically different phases of legislation were taken up with the leaders of various groups, and information was received that the highest authorities attached a great deal of importance to the alleged endorsement of compulsory health insurance by the American College of Surgeons. As the matter of the "impression" was considered to be very important, the members of the committee attempted to explain to those in high places the situation as they saw it. A man in high position indicated that he would convey, at an opportune time, to the President of the United States the information that the majority of the membership of the American College of Surgeons supported the action of the American Medical Association against compulsory sickness insurance.

Your committee calls attention to only a few of the many interviews had while on this recent trip.

From several sources in Washington, it was gratifying to learn that officials of the American Legion were sustaining the agreements made between the two groups in earlier meetings. In view of the large number of bills calling for construction of new hospitals, which had flooded Congress, an opportunity was had to verify the question of cooperation between the Legion forces and the American Medical Association.

From three different sources, information was received that no demand would be made for an appropriation for new hospital construction but that additions to hospitals if such were needed, would be financed through the allotment of funds under control

of the President, with the exception of one new hospital for Negroes and the replacement of a small institution located at Bath, N. Y.

Your committee made contact with the Legislative Committee of the American Federation of Labor as well as other important groups representing capital and industry. Many important members of Congress were visited, giving an opportunity of conveying the point of view of the medical profession. From these various contacts it was gained that members of local societies had been active in supporting the decision of this House.

Having in mind that the care of the low income group is a local problem, differing with the locality—the members of the Committee on Legislative Activities in all conferences and public contacts have pointed out that gratifying results are being developed by county societies throughout the country without the need of new legislation.

It was found that it had not been determined whether the United States Public Health Service would be given the care of the sick or differentiation between the employable and non-employable or whether those under relief would be assigned to that or some other agency. An impression was gained at that time that it would be assigned to that agency. The committee desires to bring to your attention that this would mean the enlargement of the activities of the United States Public Health Service to include the supervision and actual medical treatment of the sick. A very elaborate plan had been worked out, the details of which were given to your committee. In a few words, it was a plan which would be at this time in hands of medical men whose views are in harmony with the position of the Association. It was agreed by all that any workable plan, however sympathetically administered, would tend to promote and establish a health insurance system.

The matter of the differentiation of the employable and non-employable was then discussed with an official of the Federal Emergency Relief Administration, although it was stated that the Federal Emergency Relief Administration had not been instructed to assume this responsibility, who had recommended that men would be offered employment on the basis of their ability and experience, based on their history of normal employment prior to the depression. If they decline to accept employment, it will be up to some local agency to determine whether or not the individual is employable or in what manner his individual problem should be handled. Your committee points out that this method of handling the emergency is less disturbing, in that it does not contemplate an enlargement of the present method of handling medical relief, which is tolerable only on the basis that it is necessary to meet an emergency and must soon be discontinued. This official also stated that he did not know of any contemplated change in the medical care of the indigent and that the medical care of emergencies arising as a result of employment on the work program would be taken care of by the United States Employees Compensation Commission by physicians appointed under its jurisdiction, as it was at present being handled.

Your committee had the pleasure of discussing with a responsible representative of the President's Economic Committee the many questions which had arisen in that committee. Three of the many statements made were of particular interest.

One was that a definite impression prevailed in the minds of the President and others that the body of the profession as represented in the membership of the American College of Surgeons was committed to sickness insurance. It was considered exceedingly important that this impression be corrected if the facts were otherwise.

Second, and of extreme importance, the impression was gained that compulsory sickness insurance would not be pressed at this, nor very likely at the next session of Congress but that in all probability a bill would be presented as a sort of "trial horse" in order to obtain the public reaction.

The third important point was that a final report of the Economic Committee had not been written and that that committee was waiting for the chief statistician to report his conclusions for its information.

Knowing the personalities involved and much of the history of these matters, your committee became convinced that it would be wise for its members to go to New York for a conference

with gentlemen who were interested in social legislation, and hoped among other things to learn whether there was any influence being exerted from sources in New York to introduce at this session of Congress a bill of compulsory sickness insurance.

After considering all the factors involved, your committee felt that its duty was to explore all avenues leading to further agitation of this question and believed through past experience that personal contact and a presentation of the medical point of view would lead to a mutual understanding of the unwisdom of propaganda of this type.

As a committee we are hopeful of the future but do not deny that the next two years will require of you your active support in defending the principles you have outlined and the ideals which you cherish.

Respectfully submitted

F S CROCKETT
R. L. SENSENICH

E. H. CARL, Chairman

C. B. WRIGHT

Special Report of the Bureau of Medical Economics

Dr. R. G. Leland, Director of the Bureau of Medical Economics presented a Special Report, which was referred, without reading, to the Reference Committee on Medical Economics. on motion of Dr. Arthur J. Bedell, New York, seconded by Dr. G. Henry Mundt, Illinois, and carried.

It was moved by Dr. James F. Rooney, New York, seconded by Dr. J. D. Brook, Michigan, and carried, that the House arise from executive session into regular session.

Report of Reference Committee on Miscellaneous Business

Dr. John F. Hagerty, Chairman, presented the following report, stating that with the consent of the introducer of the resolution the committee has left out the words 'excluding all other magazines except *HYGEIA*'.

The Reference Committee on Miscellaneous Business has considered the resolution introduced by Dr. Ralph A. Fenton of Oregon, requesting the Director of Civilian Conservation Corps and the Surgeon General and other competent authorities in the war department to supply the magazine *HYGEIA* to each CCC Camp and other educational departments under their supervision, and approves of the same.

Respectfully submitted

E. N. ROBERTS
D. F. CAMERON

JOHN F. HAGERTY, Chairman

L. J. KOSMINSKY

On motion of Dr. Hagerty, seconded by Dr. William H. Mayer, Pennsylvania, and carried, the report of the reference committee was adopted.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. J. Richard Kevin, Chairman, submitted the following report:

The following portion of a resolution referred to our committee for consideration reads as follows: "Your committee further recommends that, in order to remove the menace which the Judicial Council reveals with respect to overlapping membership in state associations, the Constitution and By-Laws be so amended as to remove any further difficulty in assigning a member to the state in which he practices."

After studying the Constitution and By-Laws, your committee recommends the following modification in the By-Laws of chapter XI, section 1:

In line 19 after the word moved insert 'provided no member may hold membership in more than one constituent association at the same time.' also after the word 'Provided' in line 19 insert the word "further."

Since the provisions of the By-Laws provide that no changes in said By-Laws can be made without lying on the table twenty-four hours, your committee moves the adoption of the recommendations of the committee and a vote can be taken on Thursday which would allow the amendment to become a law at this session of the House of Delegates.

The House recessed at 4:40 p. m., to meet at 1 p. m., Thursday, June 13.

Third Meeting—Thursday Afternoon, June 13

The House of Delegates was called to order at 1 p. m. by the Speaker, Dr. F. C. Warnshuis.

Report of the Reference Committee on Credentials

Dr. J. D. Brook, Chairman, reported that Dr. E. H. Skinner, Missouri, alternate delegate for Dr. W. H. Breuer, who could not attend the session, did not have his credentials, which were being sent by air mail, but was vouched for by officers of the Missouri State Medical Association. Dr. Brook moved that Dr. E. H. Skinner be seated as a delegate from Missouri, and the motion was seconded by Dr. William H. Seemann, Louisiana and carried. He stated that 164 delegates had now been seated, and on behalf of the reference committee he thanked the delegates for the promptness with which they registered.

Roll Call

Dr. Olin West, Secretary, called the roll and announced that more than a quorum of the House had responded.

Presentation of Minutes

It was moved by Dr. J. H. Cannon, South Carolina, seconded by Dr. John Z. Brown Sr., Utah, and carried, that the Secretary be authorized to edit the minutes and publish them in *THE JOURNAL*.

Report of Reference Committee on Legislation and Public Relations

Dr. C. E. Mongan, Chairman, presented the following report:

1 With reference to the resolution offered by Dr. John F. Hagerty, on behalf of the Medical Society of the State of New Jersey, relative to S. 5, the Federal Food, Drug and Cosmetic Bill now pending in Congress, and to the enforcement of the present Federal Food and Drug Act, your committee is informed that the subject matter of this resolution has been and is under consideration by the Board of Trustees.

Your committee recommends, therefore, that this resolution be referred to the Board of Trustees.

2 With reference to the resolution offered by Dr. John F. Hagerty on behalf of the Medical Society of the state of New Jersey, relative to advertising, your committee recognizes the danger inherent in the advertising of drugs and drug products to the laity. It sees difficulty, however, in the way of compliance with the request for the refusal by the American Medical Association and its constituent state associations of all advertising whatsoever offered for publication in the journals controlled by them by pharmaceutical houses that offend against this principle.

The committee recommends that this matter be referred to the Board of Trustees for appropriate action.

3 In reference to the resolution presented by the Section on Laryngology, Otology and Rhinology, through Dr. Burt R. Shurly, your committee calls attention to the fact that the House of Delegates in 1925 and in 1930 approved certain standards of physical fitness for operators of motor vehicles, including visual, auditory and mental standards, and authorized the appointment of a committee to study the subject. It authorized also efforts to educate the public with respect to the dangers of the situation and the promotion of legislation to mitigate such dangers.

Your committee recommends that the House of Delegates reaffirm the action taken by it on this subject in 1925 and in 1930.

4 In reference to the resolution offered by Dr. J. M. Birnie on behalf of the Massachusetts Medical Society, relative to the continuation of the so called Dick scarlet fever patent and the control of this patent by the Scarlet Fever Commission, your committee reports that within the time at its disposal the assembling of evidence necessary to render judgment with respect to this matter has been impossible.

The committee recommends that the resolution be referred to the Board of Trustees.

5 In regard to the resolution of Dr. J. Richard Kevin, New York, relative to blood grouping tests, your committee finds that two practical problems are involved. First, the amending

of statutes so as to authorize courts to order individuals to submit to blood grouping tests when they are required, second, the taking of such action as may be necessary to acquaint the proper authorities in the legal profession with the existence and reliability of blood grouping tests. Your committee is of the opinion that the question of the advisability of the enactment of statutes authorizing courts to compel individuals to submit to blood grouping tests is one of law rather than of medicine, and that the House of Delegates should take no action with respect to it. With respect to the advisability of action for the purpose of acquainting proper authorities in the legal profession with the existence and reliability of blood grouping tests, your committee recommends reference to the Council on Scientific Assembly for study and report. The matter of blood grouping tests is highly technical and is one on which the membership of the House, unadvised by the Council on Scientific Assembly, should hardly be asked to express an opinion at the present time.

6 In reference to the Supplementary Report of the Board of Trustees in regard to the commercial use of the word "doctor" your committee, while condemning the use of the term "doctor" for commercial purposes, and particularly its fraudulent use for such purposes, recommends that the correction of the evil be left to action under the several state laws concerning advertising and to action before the Federal Trade Commission.

7 Your committee heartily endorses the spirit of the resolutions offered by the Medical Society of the State of New York in regard to restoring and maintaining Reserve Officers Training Camp Units in medical schools, and urges the reestablishment and maintenance of facilities for preliminary military training of medical officers in anticipation of need.

It recommends that a copy of these resolutions be sent to the President, to the Secretary of War, to the Surgeon General of the Army, and to the chairmen of the committees of the Senate and House of Representatives on Military Affairs and Appropriations.

8 In reference to the Supplementary Report of the Board of Trustees, concerning immigrant physicians a careful study of the records of the United States Bureau of Immigration fails to disclose any tendency toward an increase in the number of such physicians entering the United States, in fact, there seems to be rather a tendency toward a decrease. Moreover, immigrant physicians are not exempted from the provisions of the law allotting quotas of immigrants from the several nations of the world as was stated in the resolution adopted at the February session of the House of Delegates. They are exempted from the requirements of the Contract Labor Law prohibiting the entrance of immigrants generally who enter the United States under prearranged contracts. But no evidence has been found to show that any considerable number of immigrant physicians enter by reason of that exception. For these reasons, your committee recommends that action with respect to the resolution adopted at the Special Session in Chicago in February be held in abeyance until such time as the Board of Trustees finds evidence that will justify the enactment of legislation looking toward the exclusion of such physicians. No immigrant physician should be licensed in the United States under conditions less rigorous than those imposed on citizens of our own country.

Respectfully submitted

CHARLES E. MONGAN, Chairman
EDWARD M. PALLETTE.
E. G. WOOD
JOHN Z. BROWN SR.
SAMUEL P. MENGEL

On motion of Dr. Mongan, duly seconded and carried, the report of the Reference Committee on Legislation and Public Relations was adopted section by section and as a whole.

Report of Judicial Council

Dr. George Edward Follansbee, Chairman, stated that the Judicial Council felt that the recommendation presented by the Chairman of the Reference Committee on Amendments to the Constitution and By-Laws did not fully cover the situation which that committee was trying to correct. He suggested that he be permitted to present a substitute resolution for the recom-

mendation of the reference committee. On motion, duly seconded by Dr. Arthur T. McCormack, Kentucky, and carried, his suggestion was adopted.

Dr. Follansbee then stated that the report of the Reference Committee on Amendments to the Constitution and By-Laws did not cover the situation so as to make it necessary that each member of a constituent association be a member of a component society in that constituent association, and for that reason it did not fully correct the abuses which the Judicial Council brought up in its report. He added that the Judicial Council has therefore prepared the following resolution, which it hopes that the House will adopt in place of the recommendation offered by the Reference Committee on Amendments to the Constitution and By-Laws.

WHEREAS It is the intention that membership in this Association shall be based on membership in the component societies of constituent associations and

WHEREAS Some constituent associations admit to membership others than members of their component societies thus favoring a small number be it

Resolved That in order to equalize the privileges and duties of all members of the American Medical Association and in order to attain a fair distribution of delegates in this House based on the number of members of component societies forming each constituent association the first sentence of section 1 of chapter XI of the By-Laws be amended to read Membership in this Association shall continue only so long as the individual is a member of a component society of the constituent association through which he holds membership.

It was moved that the report of the Judicial Council be adopted. The motion was seconded by Dr. R. W. Fouts, Nebraska, and carried, after discussion by Dr. Arthur J. Bedell, New York, Dr. William D. Chapman, Illinois, Dr. Olin West, Secretary, and Dr. Follansbee.

It was moved that the first sentence of section 1, chapter XI, of the By-Laws be amended to read "Membership in this Association shall continue only so long as the individual is a member of a component society of the constituent association through which he holds membership." The motion was seconded by Dr. Arthur T. McCormack, Kentucky, and carried.

Report of the Reference Committee on Reports of Board of Trustees and Secretary

Dr. H. H. Shoulders, Chairman, presented the following report.

Your committee has considered the statement on integration of the medical profession. At its request, Dr. W. C. Woodward appeared before the committee to furnish such information as he has compiled on the subject.

Your committee developed the following facts. The "integration" of the medical profession implies the organization by statute of all licensed practitioners of medicine within a state into a public corporation, authorized by law to determine the professional fitness of persons seeking admission into the profession in that state and to supervise and regulate the professional activities of every member of it. The corporation would determine who is and who is not eligible for admission into the profession. It would supervise the conduct of every member after he has been admitted, reprimanding, suspending and removing members as circumstances dictate. A member expelled from the corporation would thereby cease to be authorized to practice medicine in the state. The corporation would take over the function of medical examining, licensing and supervising boards, the board of directors elected by the profession functioning as a board of examination and licensure.

If there were an integrated medical profession, every licensed practitioner of medicine in the state would be authorized after its initial organization under the statute creating it to vote for the directors of the corporation. Voting would probably be by districts, so that every part of the state would be represented in the management. The expenses of the corporation would be paid by assessments levied on its members by the directors.

An integrated profession is supposed by some to be better able, by reason of the democratic nature of its organization, to exercise control over the ethical and professional qualifications and conduct of the members of that profession. If the medical profession should be integrated, however, independently of the joint integration with it of osteopaths, chiropractors, naturopaths, and other cultists, the public would lose a good deal of

the benefit of integration for it is those cult groups that particularly need such supervision and control as integration implies. On the other hand, if all practitioners of the healing art were integrated into a single corporation, the votes of the osteopaths, chiropractic, naturopathic and similar groups would endanger the standards of the medical profession, and conceivably, by a combination of members of those cults, control might pass from the medical profession.

The disadvantage of integration lies in the fact that the average member of the corporation would be less likely to have a professional interest in its ethical, social and scientific activities than does the average member of such voluntary organizations as exist today. Being forced into the organization without any desire on his part and without his consent he would lack *esprit de corps*, and the poorly qualified, uninterested and unambitious member might well tend to degrade the standards of the whole group. There is no reason, however, why a medical profession integrated along the lines outlined, for purposes of ethical and professional control, should not be supplemented by private organizations devoting themselves to the protection and advancement of the science and art of healing in all its aspects.

Your committee is impressed with the possibilities for good in such a form of organization. It feels, however, that its information on the subject is not sufficient to warrant the formation of a definite policy on the subject by the House of Delegates at this time.

Your committee therefore recommends that the matter be referred to the Board of Trustees with the recommendation that the Board give careful study to the subject through the proper officers and bureaus of the Association, and that information thus gained be furnished to the various state associations by means of bulletins and communications from time to time. Your committee recommends further that the Board of Trustees make recommendations to the House at its next regular session concerning a policy on the subject.

Respectfully submitted

H. H. SHOULDERS, Chairman
BRIEN T. KING
HENRY C. MACATEE
E. F. CODY
FRED MOORE.

On motion of Dr. Shoulders, seconded by Dr. Leonce J. Kosminsky, Arkansas, and carried, the report of the reference committee was adopted.

Resolutions Opposing Acceptance of Commissions and Limiting Use of Audiometers, from Section on Laryngology, Otology and Rhinology

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, presented the following resolutions unanimously adopted by that section:

WHEREAS Certain agents and distributors of electric hearing devices have offered to physicians a commission or bonus for referring to them hard of hearing persons to whom they effect a sale, therefore be it

Resolved By the Section on Laryngology, Otology and Rhinology of the American Medical Association that it condemns as unethical and unfair to the purchaser the practice on the part of any agent or distributor of a hearing device who offers to pay to a physician or any one not an authorized agent any commission or bonus for referring a person to whom he makes a successful sale. The acceptance of such commission by a physician is interpreted as a violation of the principles of ethical practice and be it further

Resolved That it is the sense of this section that the use of audiometers in the hands of persons other than regularly qualified physicians be restricted to the measuring of hearing acuity for the purpose of detecting hearing loss and for selecting or constructing hearing aids best suited to the special needs of the individual hard of hearing person.

Dr. Shurly moved the adoption of the resolutions, and the motion was seconded by Dr. Ralph A. Fenton, Oregon, and discussed by Drs. G. Henry Mundt, Illinois, Dr. Austin A. Hayden, Trustee, and Dr. Shurly.

On motion of Dr. Arthur T. McCormack, Kentucky, seconded by Dr. Henry W. Meyerding, Section on Orthopedic Surgery, and carried, the resolutions were referred to the Judicial Council, with the request that that Council prepare and present to the profession an interpretation in consonance with the Principles of Medical Ethics.

Resolutions on Teaching and Consultation, from the Section on Ophthalmology

Dr. Emory Hill, Section on Ophthalmology, presented the following resolutions which were adopted on motion of Dr. Hill, seconded by Dr. Arthur J. Bedell, New York, and carried.

WHEREAS There have been many complaints regarding the action of some ophthalmologists in giving lectures to and consulting with opticians and optometrists and

WHEREAS It is universally conceded that to care for the diseases and conditions of the human eye demands the unusual knowledge of a graduate physician who has been especially prepared and

WHEREAS The eye is an integral part of the body, and

WHEREAS No one but a physician so trained should be permitted to diagnose treat or prescribe for eye conditions and

WHEREAS Lecture address or any other form of instruction to opticians and optometrists by ophthalmologists is not only a breach of the Principles of Medical Ethics which control our professional relationships, but is also to the detriment of the ocular health of the public by giving it a false sense of security and

WHEREAS General health and ocular comfort depend on the best medical care, therefore be it

Resolved That the Section on Ophthalmology of the American Medical Association declares that it is unethical for any member of the American Medical Association to give lectures or courses of instruction to or consult with any one not associated with the actual medical service and be it further

Resolved That the House of Delegates of the American Medical Association be asked to make a ruling to this effect.

Respectfully submitted

SECTION ON OPHTHALMOLOGY,
ARTHUR J. BEDELL, Chairman.
PARKER HEATH, Secretary

Nomination for Honorary Fellowship

Dr. Emory Hill, Section on Ophthalmology, presented the following nomination of Mr. Leslie Paton, London, England, for Honorary Fellowship, which was referred to the Council on Scientific Assembly.

Mr. Speaker and Members of the House of Delegates

The Section on Ophthalmology respectfully requests that Mr. Leslie Paton, M.A., B.Ch., M.B., F.R.C.S., of London, England, be made an Honorary Fellow of the American Medical Association.

Mr. Paton is a member of the Royal Academy, fellow and vice president of the Royal Society of Medicine, past president of the Section on Neurology, Royal Society of Medicine, past president of the Ophthalmological Society of the United Kingdom, member of the Ophthalmologische Gesellschaft, Heidelberg, honorary member of the Société française d'ophtalmologie, Sociedad oftalmológica hispano-americana, International Ophthalmic Council and the Japanese and Hungarian ophthalmologic societies. He is the author of many articles and an authority in ophthalmology and neurology.

This request is endorsed by the Section on Ophthalmology.

ARTHUR J. BEDELL, Chairman
PARKER HEATH, Secretary

Executive Session, Thursday Afternoon, June 13

On motion of Dr. Arthur J. Bedell, New York, seconded by Dr. H. B. Everett, Tennessee, and carried, the House went into executive session at 2:10 p.m.

Report of Reference Committee on Medical Economics

Dr. W. F. Braasch, Chairman, presented the following report.

On reviewing the special report issued by the Bureau of Medical Economics presented at the Executive Session of the House of Delegates on Tuesday afternoon, your committee is first impressed with its excellence and completeness. In consideration of the details of this report, your committee desires to call your attention to that part of the report on pages 20 to 23 inclusive which deals with the dangers inherent in any plan for distribution of medical care other than the present plan. Specifically, these dangers are listed under violations of medical ethics, methods of collection of payment for medical care, inflexibility of plans, and violations of ethics by groups. Your careful perusal of these pages is recommended.

Your further attention is directed to any conflict that might arise as a result of nonobservation of the ten principles laid down at the Cleveland session in 1934 and reaffirmed at the Special Session of the House of Delegates in February 1935 in Chicago, which are principles of a positive nature. These warnings may seem superfluous but we must remember that we are embarking on uncharted seas and it behooves us to proceed cautiously. Your committee suggests the insertion of the following statement just prior to the subheading "Good Plans Subject to Imitations" on page 24:

In designing and operating plans to provide medical care for the indigent and low income groups, county medical societies may well consider the dangerous destructive and unethical tendencies which even the most carefully conceived and constructed plan may assume. Some of these may follow an incomplete or inaccurate preliminary estimate of the medical situation; some may result from the unpredictable factor of human nature; others may follow as the natural outcome of changes in the general economic conditions entirely beyond the control of the medical profession. Regardless of the causative factors which may vary in different communities, county medical societies must be prepared to recognize and deal with complications affecting the organization of medical care under the specifications of a county plan just as their members are trained to deal with complications which often occur to change the course of the diseases which they treat. Some of these dangers and complications are:

- 1 The adoption and operation of a medical plan where it is unnecessary
- 2 The stimulus aroused by good plans among irresponsible organizers to develop and operate imitations and counterfeits
- 3 The establishment in medical practice of dangerous patterns following the adoption of undesirable types of plans
- 4 The compromise of medical societies in the corporate practice of medicine or in the operation of insurance companies as a result of an insufficient study of state statutes and case law
- 5 Failure in the operation of a plan to conform to the Principles of Medical Ethics
- 6 The almost inevitable transition of voluntary insurance plans into compulsory contributory sickness insurance systems operated by the state
- 7 The difficulties involved in or the failure adequately to provide for complete control of medical affairs by the medical profession
- 8 The freezing of medical fees at a point below that which is consistent with good medical service
- 9 Failure to bear constantly in mind that a medical society plan is an experiment in the methods of distributing medical service and that it may have only a temporary usefulness; may need frequent or drastic modifications or may need to be discarded entirely
- 10 Medical society plans must not be considered or accepted as a substitute for the regular practice of medicine as applied to the majority of people. If it is believed such plans may be useful they should be considered merely as supplementary facilities in the distribution of medical service. They should be used only so long and in such a manner as they serve efficiently to make more easily available to low income groups a high quality of medical care.

On page 16 of the report, your committee recommends that the sentence "Except for the indigent, the provision for medical service in minor illnesses is seldom an important problem" be changed to read "Except for the indigent, the provision for medical service in minor illnesses is seldom an important economic problem."

Your committee recommends a modification of the statement on the bottom of page 16: "Economic complexities make it impossible for the modern physician to have such detailed individual knowledge. Accurate appraisal now requires expert specialized work too extensive to be undertaken by the physician himself." Your committee believes that the family doctor often knows as much about the economic status of his patient as do social service workers. Although the periodic investigation by the trained social worker has a definite place, such social investigation should not supplant the knowledge acquired by the family physician in his intimate contacts.

Your committee believes that the first paragraph of the quoted section on page 17 referring to experiments conducted in Oakland County, Mich., be deleted and that the quotation be followed by the following paragraph: "Social service work as applied to medical service should always be guided by medical opinion."

A paragraph on page 26 of the special report reads: "Regardless of whether or not a plan to make medical services more easily available in a community is thought advisable it is to be hoped that the medical profession will never surrender or renounce that age-old privilege of relieving the suffering of those who are unable to pay." Your committee suggests that this paragraph be changed to read: "Regardless of whether

or not a plan to make medical service more easily available in a community is thought advisable, it is believed that the medical profession will never surrender or renounce that age-old privilege of relieving the suffering of those who are unable to pay."

Your committee suggests that the contemplation of medical society plans should be a joint responsibility of state and county medical societies, and that county medical societies should confer with the officers of their respective state associations relative to principles and procedures in order that the necessity for and nature of medical service plans be properly safeguarded.

Your committee would recommend that adequate provision be made for the continuance and expansion of the most important work of the Bureau of Medical Economics.

Your committee would recommend that this report be made available to the state organizations for distribution by their officers to every component member with the feeling that it is highly desirable that the information in this report be read by every physician.

Your committee wishes again to commend the Bureau of Medical Economics for the excellent special report which it has made and also wishes to commend the Board of Trustees on the complete cooperation that that Board has at all times given to the Director of the Bureau of Medical Economics.

Respectfully submitted

W. F. BRAASCH, Chairman
CHARLES J. WHALEN
FRED B. CLARKE
GUY W. WELLS
H. A. LUCE.

On motion of Dr. Braasch, duly seconded and carried, the report was adopted by sections and as a whole.

It was moved by Dr. Arthur J. Bedell, New York, seconded by Dr. William H. Mayer, Pennsylvania, and carried, that a few paragraphs indicating the general trend of the action of the House be prepared for release to the press and that the complete report be not released until it has been modified according to the recommendations of the Reference Committee on Medical Economics.

Conference with Leaders of American College of Surgeons

Dr. E. H. Cary, Texas, and Dr. James S. McLester, President, addressed the House on their impressions gained from a conference with leaders of the American College of Surgeons who agreed with the action of the House of Delegates of the American Medical Association taken at its session held in Chicago in February 1935.

The House arose from Executive Session on motion of Dr. James F. Rooney, New York, seconded by Dr. J. H. Cannon, South Carolina, and carried.

Dr. Olin West, Secretary, on request of the Speaker, read section 1, chapter IV, of the By-Laws referring to nominations.

ELECTION OF OFFICERS

Election of President-Elect

Dr. J. C. Whalen, Illinois, nominated for President-Elect Dr. Charles E. Humiston, Chicago.

Dr. Brien T. King, Washington, nominated Dr. J. Tate Mason, Seattle.

Dr. William H. Mayer, Pennsylvania, nominated Dr. J. Norman Henry, Philadelphia.

Dr. Emory Hill, Section on Ophthalmology, nominated Dr. Harvey Cushing, New Haven, Conn.

The speaker declared the nominations closed and appointed as tellers Drs. G. Henry Mundt, Illinois, J. R. McVay, Missouri, James Q. Graves, Louisiana, Vernon L. Treyner, Iowa, and C. W. Roberts, Georgia.

The Secretary announced that 158 delegates had been recorded as present and that 155 votes had been cast, of which Dr. Charles E. Humiston received 40, Dr. J. Tate Mason, 64, Dr. J. Norman Henry, 22, and Dr. Harvey Cushing, 29.

The Speaker announced that as no candidate had received a majority vote, a second ballot would be taken, eliminating the name of the one having received the least number of votes.

The Secretary announced that 158 delegates had recorded their presence and that 152 votes had been cast, of which Dr Charles E. Humiston received 34, Dr J. Tate Mason, 87, and Dr Harvey Cushing, 31.

The Speaker declared Dr J. Tate Mason, having received the majority of the votes cast, elected President-Elect of the American Medical Association.

Election of Vice President

Dr J. H. Cannon, South Carolina, nominated for Vice President Dr Kenneth M. Lynch, Charleston, S. C., and the nomination was seconded by Dr Walter E. Vest, West Virginia.

Dr William H. Mayer, Pennsylvania, moved that the nominations be closed, and the motion was seconded by Dr Arthur J. Bedell, New York, and carried.

On motion of Dr Arthur C. Morgan, Pennsylvania, seconded by Dr William H. Myers, Georgia, and carried, the Secretary cast the ballot of the House for Dr Kenneth M. Lynch as Vice President for the ensuing year, and the Speaker declared Dr Lynch elected Vice President.

Election of Secretary

Dr Orrin S. Wightman, New York, nominated Dr Olin West, Chicago, to succeed himself as Secretary of the American Medical Association. On motion of Dr A. A. Walker, Alabama, seconded by several and carried unanimously, the nominations were closed.

On motion of Dr A. A. Walker, Alabama, seconded by Dr Horace Reed, Oklahoma, and carried, the Speaker cast the ballot of the House for Dr Olin West as Secretary of the American Medical Association and declared Dr West elected Secretary for the ensuing year.

Election of Treasurer

Dr J. H. J. Upham, Chairman of the Board of Trustees, nominated for the office of Treasurer Dr Herman L. Kretschmer, Chicago. The nomination was seconded by Dr W. F. Braasch, Minnesota. Dr Arthur T. McCormack, Kentucky, moved that the nominations be closed, and the motion was seconded by Dr Joseph F. Smith, Wisconsin, and carried.

Dr B. F. Bailey, Nebraska, moved that the Secretary be instructed to cast the ballot of the House of Delegates for Dr Herman L. Kretschmer, Chicago, as Treasurer. The motion was seconded by Dr J. H. Cannon, South Carolina, and carried, and the Secretary cast the vote of the House for Dr Herman L. Kretschmer, Chicago, as Treasurer of the Association for the ensuing year and the Speaker declared Dr Kretschmer so elected.

Election of Speaker of the House of Delegates

Dr James S. McLester, President, took the chair and announced that the next order of business was the election of a Speaker of the House of Delegates.

Dr James F. Rooney, New York, nominated for Speaker of the House of Delegates Dr Nathan B. Van Etten, New York.

Dr T. Henshaw Kelly, California, nominated Dr F. C. Warnshuis, San Francisco, and the nomination was seconded by Dr B. F. Bailey, Nebraska.

On motion of Dr J. D. Brook, Michigan, seconded by Dr Walter F. Donaldson, Pennsylvania, and carried, the nominations were closed and the tellers spread the ballot.

The Secretary announced that 159 delegates had been recorded as present and that 151 votes had been cast, of which Dr Nathan B. Van Etten received 80 and Dr F. C. Warnshuis 71.

The President declared Dr Nathan B. Van Etten, New York, elected Speaker of the House of Delegates for the ensuing year.

Election of Vice Speaker of the House of Delegates

The Speaker, Dr F. C. Warnshuis, resumed the chair and after presenting Dr Nathan B. Van Etten, the newly elected Speaker, declared that nominations were in order for Vice Speaker of the House.

Dr B. F. Bailey, Nebraska nominated for Vice Speaker Dr R. W. Fouts, Omaha.

Dr H. B. Everett, Tennessee, nominated Dr H. H. Shoulders, Nashville, Tenn.

The Speaker declared the nominations closed and requested the tellers to spread the ballot.

The Secretary announced that 159 delegates had recorded their presence and that 143 votes had been cast, of which Dr R. W. Fouts had received 54 and Dr H. H. Shoulders 89.

The Speaker declared Dr H. H. Shoulders, Nashville, Tenn., elected Vice Speaker of the House of Delegates of the American Medical Association, as he had received the majority of the votes cast.

Address of President-Elect J. Tate Mason

Gentlemen of the House, I want to thank you from the bottom of my heart for the honor that you have bestowed on me, and I hope that I shall be worthy, I shall try to be worthy throughout my régime.

As I came up the steps with the men from my state I could not help remembering that forty-two years ago this month my father an old country practitioner of Virginia, brought me to Atlantic City, and on the sands here close to this hotel told me something of the ethics and the principles of ethics of medicine. I want you gentlemen to know that I think that those principles have changed none up to date. I know that in these changing times when some of our men have been somewhat apprehensive and some have been restless, if those men will just look over the last fifty years of the service that the physicians of America have given to this country they cannot be but satisfied. I feel that probably the only thing that we need to push forward at the present time is to know how to teach these men what has gone on before and to have more cooperation probably among ourselves than we have had in the past.

Election of Trustees

The Speaker declared the next order of business to be the election of a trustee for a term of five years to succeed Dr Joseph A. Pettit, Portland, Ore., whose term expired this year and who, according to the By-Laws, was not eligible for reelection.

Dr William R. Molony Sr., California, nominated Dr George H. Kress, Los Angeles.

Dr Burt R. Shurly, Section on Laryngology, Otology and Rhinology, nominated Dr Ralph A. Fenton, Portland, Ore.

Dr Bundy Allen, Florida, nominated Dr Albert Soiland, Los Angeles.

As there were no other nominations, the Speaker declared the nominations closed and asked the tellers to spread the ballot.

The Secretary announced that 159 delegates had been recorded as present and that 141 votes had been cast, of which Dr George H. Kress received 40, Dr Ralph A. Fenton 79 and Dr Albert Soiland 22.

The Speaker declared Dr Ralph A. Fenton, Portland, Ore., elected for a term of five years to succeed Dr Joseph A. Pettit, since Dr Fenton had received the majority of the votes cast.

The Speaker called for nominations for the office of trustee to be elected for a term of five years to succeed Dr J. H. J. Upham, Columbus, Ohio, whose term expired this year and who, according to the By-Laws, was not eligible for reelection.

Dr R. L. Sensenich, Indiana, nominated Dr F. S. Crockett, La Fayette, Ind.

Dr Walter E. Vest, West Virginia, nominated Dr James R. Bloss, Huntington, W. Va.

Dr L. J. Hirschman, Michigan, nominated Dr Carl F. Moll, Flint, Mich.

The Speaker, hearing no other nominations, declared the nominations closed and asked that the ballots be prepared.

The Secretary stated that 159 delegates had been recorded as present and that 142 votes had been cast, of which Dr F. S. Crockett received 33, Dr James R. Bloss 64 and Dr C. F. Moll 45.

Since no one had received a majority of the votes cast, a second ballot was spread for the two candidates having received the greatest number of votes.

The Secretary announced that 159 delegates had recorded their attendance and that 133 votes had been cast, of which Dr James R. Bloss received 89, and Dr Carl F. Moll 44.

The Speaker declared Dr James R Bloss, Huntington, W Va, elected for a term of five years to succeed Dr J H J Upham, since Dr Bloss had received the majority of the votes cast

Nominations for Standing Committees

Dr James S McLester, President, presented the following nominations for standing committees

Judicial Council Dr George Edward Follansbee, Cleveland, to succeed himself for a term ending in 1940

Council on Medical Education and Hospitals Dr Reginald Fitz Boston, to succeed himself for a term ending in 1942

Council on Scientific Assembly Dr A A Walker, Birmingham, Ala, to succeed Dr Frank Smithies, for a term ending in 1940

On motion of Dr Arthur T McCormack, Kentucky seconded by Dr Burt R Shurly, Section on Laryngology, Otology and Rhinology, and carried, the House confirmed the nominations

Election of Honorary, Affiliate and Associate Fellows

APPLICANT FOR HONORARY FELLOWSHIP

On motion of Dr Arthur J Bedell, New York, seconded by Dr Burt R Shurly, Section on Laryngology Otology and Rhinology and carried, Mr Leslie Paton London, England whose nomination by the Section on Ophthalmology had been approved by the Council on Scientific Assembly, was elected to Honorary Fellowship

APPLICANTS FOR AFFILIATE FELLOWSHIP APPROVED BY THE COUNCIL ON SCIENTIFIC ASSEMBLY

Barton A A Plains Pa

Place of 1936 Annual Session

The Speaker announced that the next order of business was the selection of the place of the 1936 annual session and called on the Board of Trustees for nominations

Dr J H J Upham, chairman of the Board of Trustees, presented the following report

Mr Speaker and Members of the House The Board of Trustees reports that invitations have been received from

Indianapolis, Miami, Fla, Chicago, and Kansas City, Mo Representatives of the Board of Trustees have investigated the facilities of the cities from which invitations have been received, and the Board reports that Kansas City, Mo., and Chicago have adequate facilities for taking care of the annual session

Dr J R McVay, Missouri, extended an invitation from the medical profession of Missouri and Kansas to have the American Medical Association meet in Kansas City, Mo, in 1936 The nomination of Kansas City was seconded by several

Dr Isaac A Abt, Section on Pediatrics, extended an invitation from the medical profession of Chicago to have the Association meet in that city in 1936

The Speaker requested that the ballot be spread, and the Secretary announced that 159 delegates had been recorded as present and that 126 votes had been cast, of which Chicago received 13 and Kansas City, Mo, 113

The Speaker declared that the House of Delegates had selected Kansas City, Mo, for its 1936 session

Vote of Appreciation

Dr J Newton Hunsberger, Pennsylvania, moved that the House of Delegates extend a vote of appreciation to all those who had been concerned with the Atlantic City session and who had made the stay so pleasant and profitable The motion was seconded by Dr E G Wood, Tennessee, and carried unanimously

The House of Delegates adjourned sine die at 4 45 p m

(To be continued)

Association News

THE ATLANTIC CITY SESSION

Report of the Golf Tournament

One hundred and thirty-two medical golfers from the United States and Canada played the interesting and baffling Northfield Country Club course in Atlantic City on the occasion of the twenty-first annual tournament of the American Medical Golfing Association. Rain postponed play in the tournament from Monday to Tuesday, June 11, when the contestants teed off from 7:30 a. m. to 3 p. m. Thirty-six holes were played by most of the entrants, but about twenty were satisfied with eighteen holes and entered the events limited to that play. Sixty trophies and prizes were awarded after the dinner, which was presided over by Dr. Charles Lukens of Toledo, Ohio. Dr. Walt P. Conaway, chairman of the Atlantic City Golf Committee, made the presentations.

CHAMPIONSHIP WON BY DR. L. C. FOSTER OF NEW HAVEN

The championship was won by Dr. L. C. Foster of New Haven, Conn., who turned in a score of 80-79—159 for thirty-six holes. He received the famous Will Walter Trophy. The Handicap Championship was won by Dr. W. H. Taylor of Greensburg, Pa., who bagged the Detroit Trophy. The Eighteen Hole Championship went to Dr. L. W. Pumphrey of Pittsburgh, who took home the Golden State Trophy. Second prize in this event went to Dr. E. G. Brittain of Bound Brook, N. J. Third prize to Dr. W. T. Lemmon of Philadelphia and fourth prize to Dr. D. M. Houston of Seattle. The Eighteen Hole Handicap Championship was awarded to Dr. D. Ray Murdock of Greensburg, Pa., who won the Ben Thomas Trophy. Second prize went to Dr. Jacob Manting of Detroit.

DRS. CULLOM AND CROSKY ARE WINNERS

The Maturity Event, limited to Fellows over 60 years of age, for the best eighteen holes net, was won by Dr. M. M. Cullom of Nashville, Tenn. He received the Minneapolis Trophy. Second prize went to Dr. George Hall, Chicago, and third prize to Dr. H. V. Hubbard of Philadelphia. Dr. John Welsh Crosky of Philadelphia won the Old Guard Championship, awarded to past presidents of the A. M. G. A. Dr. Crosky carded a sterling 71 net for eighteen holes and received the Wendell Phillips Trophy. Second prize was won by Dr. Will Walter of Charlottesville, Va., who organized the A. M. G. A. in 1915, and third prize by Dr. E. G. Zabriskie of New York.

FIVE FLIGHTS

The Championship Flight low gross was won by Dr. R. M. Harris of Miami, Fla., who gained the St. Louis Trophy. Other winners were Dr. J. J. Marek of Cleveland, Dr. R. C. Glenn of State College, Pa., and Dr. J. M. Dorsey of Rochester, Minn. The net prizes in this flight went to Dr. A. H. Weiland of Miami, who won the President's Trophy, presented by Dr. Charles Lukens. Dr. S. G. Pontius of Lancaster, Pa., won the second low net prize.

The First Flight gross winners were Dr. Roy E. Emanuel of Chickasha, Okla., Dr. W. C. Jones of Miami, Fla., and Dr. D. C. Brennan of Akron, Ohio. First prize among the nets was the Chairman's Trophy, presented by Dr. Walt P. Conaway and won by Dr. A. C. Smith of Wooster, Ohio. Second prize went to Dr. H. R. Mather of Latrobe, Pa., and third prize to Dr. W. B. Swartley of Philadelphia.

The Second Flight gross winners were Dr. C. P. Rutledge of Shreveport, La., Dr. O. E. Satter of Prairie du Chien, Wis., and Dr. Harry Mock of Chicago. Net prizes went to Dr. F. A. Carroll of Scranton, Pa., and Dr. J. E. Rannels of Scotch Plains, N. J.

The Third Flight gross winners were Dr. H. M. Schuffell of Canton, Ohio, Dr. S. B. Muncaster of Washington, D. C., and Dr. B. R. Almqvist of Pittsburgh. Net winners were Dr. W. Earl Clark of Washington, D. C., Dr. Anthony Bassler of New York, and Dr. John B. Morgan of Cleveland.

The Fourth Flight winners (net only) were Dr. J. S. Anderson of Greensburg, Pa., Dr. O. B. Snyder of Greensburg, Pa., Dr. O. A. Brines of Detroit, Dr. H. R. Miner of Falls City, Neb., Dr. H. N. Dorman of Washington, D. C., Dr. Joseph F. Hawkins of Providence, R. I., Dr. H. O. Barnes of Los Angeles and Dr. J. J. Waygood of Philadelphia.

The Kickers' Handicap was won by President Lukens of Toledo, Dr. G. G. Johnson of San Francisco, Dr. C. E. Moore of Harrisburg, Pa., Dr. J. W. Rae of Toledo, Ohio, Dr. W. H. McCombs of Pittsburgh, Dr. L. P. Sheedy of Pittsburgh, Dr. W. A. Cook of Tulsa, Okla., and Dr. W. L. Crawford of Rockford, Ill.

DR. W. E. GRAY WINS INTERNATIONAL EVENT

Dr. W. E. Gray of Milltown, New Brunswick, won the International Event and took home the beautiful trophy presented by Dr. Lukens, president of the A. M. G. A. The Ontario Event, symbolic of the Canadian Medical Association golf championship, was won by Dr. L. J. Austin of Kingston, Ont. Dr. F. E. Sinclair of Westminster, B. C., was second in this event.

Three special prizes were awarded. For the Fellow with twelve children, Dr. A. C. Smith was presented with an appropriate prize, the best dressed man, Dr. D. J. Leithauser of Detroit was well rewarded for his meticulousness, the most handsome man, Dr. John Pennington of Atlantic City, won the beauty award of the day.

ELECTION OF OFFICERS

Dr. M. M. Cullom of Nashville, Tenn., was chosen president of the A. M. G. A. for the ensuing year. Dr. W. Albert Cook of Tulsa, Okla. was elected first vice president, Dr. Walt P. Conaway of Atlantic City, N. J., second vice president. Dr. Lukens was made a member of the board of directors, composed of past presidents. The next tournament will be held in Kansas City at the time of the annual meeting.

MEDICAL BROADCASTS

Network programs broadcast weekly over the National Broadcasting Company and the Columbia Broadcasting System have been discontinued for the summer. Notice of resumption will be published several weeks prior to the first of the new series of programs. It is probable that the radio broadcasts will be resumed about October 1.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Bill Introduced—H. 655 proposes to repeal the laws regulating the possession, sale or distribution of narcotic drugs and to enact what apparently is the uniform narcotic drug act.

CALIFORNIA

Assign Additional Inspectors to Spider Problem—Fourteen new health inspectors were assigned to the Belvedere Gardens district of Los Angeles, June 19, to clean out the venomous black widow spider, which has infested the area. According to the *Chicago Tribune*, prevalence of the insect has been reported in other local areas.

DISTRICT OF COLUMBIA

Medical Bills in Congress—Bill Introduced S. 3084, introduced by Senator Copeland, proposes to make it unlawful in the District of Columbia for any physician, dentist or veterinarian to compound, manufacture or dispense any chemical, drug or medicine, for use as a medicine, even for his own patient, unless he has been licensed by the board of pharmacy as a medical "dispenser," dental "dispenser" or veterinary "dispenser." Physicians, dentists and veterinarians who are eligible to practice their respective professions in the District of Columbia when the bill becomes effective and who have been accustomed to compound, manufacture and dispense drugs and medicines for use by their own patients may be licensed by the board of pharmacy without examination. The qualifications of all other physicians, dentists and veterinarians are to be determined by the board of pharmacy, consisting of five pharmacists. A physician, dentist or veterinarian must pay to the board of pharmacy at the time of

examination a fee of \$10. Every physician, dentist and veterinarian who is licensed, whether with or without examination, must pay the board a fee of \$3 when he is licensed and a like fee every three years thereafter. The board of pharmacy is to be authorized to suspend or revoke the license of any medical, dental or veterinary "dispenser" for causes stated in the act.

The bill contains provisions intended to regulate the sale of poisons, including barbitol and derivatives of barbituric acid. It proposes that no medicine of any kind shall be compounded, manufactured or dispensed, or sold or distributed at retail, by any person other than a registered pharmacist, except that medical, dental and veterinary "dispensers" licensed by the board of pharmacy are to be permitted to compound, manufacture and dispense drugs for the sole use of their respective patients.

The board of pharmacy, if this bill be enacted, is to take over the duties of the health department and the police department in the enforcement of laws enacted for the District of Columbia and pertaining to the practice of pharmacy, the manufacture, production, sale, distribution and standard of strength and purity of drugs, chemicals and poisons. Since this bill proposes to reenact provisions of the present law relating to the treatment of persons addicted to the use of cocaine, morphine, opium and chloral hydrate, the bill proposes in effect that the board of pharmacy shall have supervision and control of the treatment of such addicts.

GEORGIA

New Headquarters for State Association—The Medical Association of Georgia moved, June 5, to new headquarters in the Atlanta Academy of Medicine and Dentistry. Until that time the association had held council meetings in the academy building.

Dr Bunce Honored—Dr Allen H Bunce, Atlanta, who has been secretary of his state association since 1920, was presented with a gold watch by the Medical Association of Georgia in recognition of his many years of service. Dr William R Dancy, Savannah, made the presentation on behalf of members of the association at a banquet of the Fulton County Medical Society. Dr Bunce has also been a member of the Board of Trustees of the American Medical Association for six years.

Society News—Speakers before the Eighth District Medical Society, April 9, included Drs Millard E Winchester, Brunswick, on "Use of Atabrine in Control of Malaria," and Marvin F Haygood, Atlanta, "Place of Surgery in the Treatment of Pulmonary Disease."—Dr Quinney A Mulkey, Millen, read a paper on "Relationship of the Doctors and Druggists" before the Burke-Jenkins-Screven Counties Medical Society at Millen, April 4.—Dr Cleveland Thompson, Millen, among others, addressed the Tattnall County Medical Society in Reidsville, April 12, on "Peritonitis."—At a meeting of the Muscogee County Medical Society, April 11, Dr James H McDuffie Jr, Columbus, discussed fibroids complicating pregnancy.—Dr Cyrus W Strickler presented a paper before the Fulton County Medical Society in Atlanta, April 4, entitled "Forced Spinal Drainage in Epidemic Encephalitis."—At a meeting of the Atlanta Academy of Medicine, June 20, Dr Edgar Boling presented a paper on "Treatment of Septic Peritonitis."

ILLINOIS

Bill Introduced—S 659, to amend the workmen's compensation act, proposes to make compensable occupational diseases arising out of any employment covered by the act.

Bill Passed—H 814 has passed the house, proposing to authorize the formation of corporations to operate nonprofit hospital service plans "whereby hospital service may be provided by the said corporation or hospital with which it has a contract for such care to those persons who become subscribers to said plan under a contract which entitles each subscriber to certain hospital care."

Society News—Dr Philip Lewin, Chicago, discussed arthritis before the Fulton County Medical Society, June 20.—At a meeting of the McHenry County Medical Society, June 20, Dr George de Tarnowsky, Chicago, spoke on the treatment of fractures.—Dr Leon Unger, Chicago, spoke on "Allergy, with Special Reference to Recent Advances in Hay Fever," before the Du Page County Medical Society, May 15.

Chicago

Hospital News—The tenth anniversary of the Illinois Educational and Research Hospital, operated jointly by the state department of public welfare and the University of Illinois College of Medicine, was observed, June 6, the program included the unveiling of a fountain statue symbolizing the fight by science and medicine to protect humanity from disease. A. L. Bowen, Springfield, director, state department of public welfare made the principal address.

Society News—Dr Irving F Stein's presidential address before the Chicago Gynecological Society, June 7, was entitled "A Consideration of the Phenomenon of Ovulation and Its Relation to the Sex Cycle", Luther S H Gable, PhD, discussed "Adventure with Radium."—Dr Thomas P Foley was chosen president-elect of the Chicago Medical Society at its annual meeting, June 19, and Dr Julius H Hess was installed as president. Dr Robert H Hayes was named secretary.

INDIANA

Society News—The Third District Medical Society held its semiannual meeting in Corydon, May 10, to observe the founding of the Indiana State Medical Association one hundred and fifteen years ago. Speakers included Drs Charles Emery, Bedford, on burns, Donald L Colglazier, Salem, hematology in general practice, James O Ritchey, Indianapolis, pulmonary complications of influenza.—The Davies Martin Counties Medical Society was addressed, May 28, by Dr Homer H Wheeler, Indianapolis, on "Carcinoma of the Rectum."—At a meeting of the St. Joseph County Medical Society in South Bend, May 8, Dr James H Stygal, Indianapolis, discussed "Differential Diagnosis of Chest Conditions." The society held its annual "doctors' party," May 22.—Dr Edward B Ruschli, Lafayette, spoke on fracture of the hip joint before the Fountain-Warren Counties Medical Society in Covington, June 6.—The Jefferson County Medical Society was addressed in Madison, May 27, by Dr John M Townsend, Louisville, Ky, on the "Irritable Female Bladder and Urethra." Dr Adolph B Loveman, Louisville, discussed diagnosis and treatment of the commoner skin conditions.—Dr Paul D Crimm, Evansville, was elected president of the Indiana Tuberculosis Association at its annual meeting in Indianapolis, April 16-17.

IOWA

A Death from Smallpox—The state health department reports the death of a middle aged man from smallpox during the week ended June 15. The man lived in a rural area in Warren County and had never been successfully vaccinated against smallpox.

Typhoid During 1934—There were 285 cases of typhoid reported to the state department of health in 1934, with fifty-four deaths. Six typhoid carriers were discovered in the investigations. Excluding cases associated with milk-borne outbreaks, which occurred at Waterloo, Boone and Fontanelle during the year, there were 141 cases representing what is often designated "residual" or endemic typhoid, the state journal reports.

Society News—Dr Tobias L Burnberg, St Paul, discussed "Eczema in Children" before the Cerro Gordo County Medical Society in Mason City, April 9.—At a meeting of the Cherokee County Medical Society, April 16, Dr Lester J Spinharney, Cherokee, spoke on hydramnios.—A symposium on obstetrics was presented before the Harrison County Medical Society in Missouri Valley, April 3, by Drs Roy H Cutler, Little Sioux, and Charles S Kennedy, Logan.

KANSAS

Society News—Dr Francis S Carey, Kansas City, presented a paper on "Common Complications Following Abdominal Operations and Their Treatment," at a recent meeting of the Wyandotte County Medical Society.

State Practically Free from Bovine Tuberculosis—The U S Department of Agriculture officially recognized Kansas as the nineteenth state practically free from bovine tuberculosis, May 1, thus establishing it as a modified accredited area, where tuberculosis among cattle has been reduced to less than 0.5 per cent. Other states are North Carolina, Maine, Michigan, Indiana, Wisconsin, Ohio, Idaho, North Dakota, Nevada, New Hampshire, Utah, Kentucky, West Virginia, Washington, Illinois, Oregon, Virginia and Minnesota. The campaign to eradicate bovine tuberculosis is progressing rapidly in other states. During March, 2,690,074 cattle in about 250,000 herds were tested, more than in any previous month in the history of the work.

MAINE

Society News—At a meeting of the Kennebec County Medical Association in Togus May 16, speakers included Drs Edward G Ahrens, "Recent Advances in the Treatment of Asthma", Hanson T Perkins, "Role of Electrocardiography in Modern Medicine", James K. Nealon, "Treatment of Pyelonephritis", Joseph E. Wheeler, "Treatment of Ununited Fractures of Long Bones," and Harry A Goalwin "Reconstructive

Surgery of the Eyelids and Lacrimal Passages"—Dr Seth M. Milliken, New York discussed "Traction in the Treatment of Fractures" before the Cumberland County Medical Society, April 25

MARYLAND

Resolution on Certified Milk.—The following resolution was adopted, May 17, by the Medical Milk Commission of the Medical and Chirurgical Faculty of Maryland

That the requirements for the production of certified milk under the Medical Milk Commission of Maryland shall include the regulations governing the production and handling of selected raw milk required by the Baltimore City Health Department in addition to such regulations as are found in the methods and standards for the production of certified milk adopted by the American Association of Medical Milk Commissions or as established by the Maryland Medical Milk Commission

This action refers to the regulations governing the production and handling of selected raw milk adopted by the commissioner of health of Baltimore recently and assures a single standard of sanitary requirement for the certified milk on sale in Baltimore

Appeal for Funds Successful.—Two years of charity work at Johns Hopkins Hospital, Baltimore, have been assured as a result of its recent appeal for funds, the first in many years. The campaign opened at a banquet, April 23. Recent reports state that the goal of \$200,000 has been exceeded by \$26,241. The institution provides 36 per cent of all local charity hospitalization, it was stated. Funds obtained in the recent campaign will enable the hospital to continue this work for two years and to open beds now closed in the children's surgical ward and the women's clinic. The success of the campaign and the forty-sixth anniversary of the opening of the hospital were observed at a luncheon, May 9, at which Dr. Simon Flexner, New York, director of laboratories of the Rockefeller Institute for Medical Research, was the principal speaker

MICHIGAN

Dr. MacCracken Resigns as Dean.—The resignation of Dr. Walter H. MacCracken as dean of Wayne University College of Medicine on account of ill health has been announced. He has held the position concurrently with his appointment as professor and head of the department of pharmacology and therapeutics since 1919. He will continue with the latter position. Aged 65, Dr. MacCracken is a graduate of the University of Louisville School of Medicine, class of 1903. Dr. William J. Stapleton Jr., Detroit, has been named assistant dean, it was stated. Wayne University College of Medicine was formerly known as Detroit College of Medicine

A Medical Symphony Orchestra.—The Wayne County Medical Society Symphony Orchestra will present its concerts next season at the Scottish Rite Cathedral of the Masonic Hall and the Art Institute. The orchestra has been rehearsing weekly, under the direction of Mr. Georges Miquelle. The personnel of the orchestra is

Violins: Drs. Raphael Altman, concert master; Jacob Agins, John D. Bryce, Charles R. Davis, Henry C. Galantowicz, Samuel D. Jacobson, Ezra Lipkin, D. Anneska Marcelli, Leon Rottenberg and Stephen S. Skrzycki.

Viola: Max Beitman.
Cello: Drs. Eugene A. Osins and William P. Woodworth.
Piano: Dr. Frank M. MacKenzie.
Saxophone: Dr. Edward W. Krass and Gerald Wilson Jr.
Clarinet: Drs. George C. Burr and Roy D. Tupper.
Trumpet: Drs. Arthur E. Hammond and Gerald A. Wilson Paul.
Walker and Miss Phyllis Hyde.
Flute: Dr. George H. Palmerlee.
Trombone: Dr. Fred W. Hyde and Fred Hyde Jr.
Percussionist: Harold C. Kahn, D.D.S.

The society's glee club is made up of Mr. Arthur H. J. Searle, director, first tenors, Drs. Lloyd E. Crick, Edwin J. Hammer and Rudolph W. Lignell, second tenors, Drs. Agins, Laslo Galdonyi and Douglas A. Jackson, baritones, Drs. John N. Salowich, Leo P. Rennell and Harry A. Pearse, basses, Carleton Fox, D.D.S., and Drs. Paul G. Brownell, Francis T. McCormick and Frank M. MacKenzie. Dr. MacKenzie is president of the orchestra, Dr. Woodworth, vice president, Dr. Agins, secretary, and Dr. Arthur E. Hammond, treasurer.

MINNESOTA

Fifty Years of Practice.—The Hennepin County Medical Society sponsored a dinner in honor of several of its members who have completed fifty years in the practice of medicine. The guests of honor were Drs. Thomas S. Roberts, Edward Josiah Brown, Thomas F. Qunby, Jesse E. Long, Richard Olding Beard, Horatio B. Sweetser Sr., Ethelbert O. Cosman, Henry L. Staples, John Phineas Barber, Henry Hooker Leavitt and Ralph St. John Perry. Dr. William B. Linton and Dr. Brown, a past president of the society, were unable to attend.

Seventy-Fifth Anniversary Celebrated.—The seventy-fifth anniversary of the first medical organization in Ramsey County was observed with a stag dinner at the Minnesota Club, St. Paul, May 18. According to *Minnesota Medicine*, the establishment of the St. Paul Academy of Medicine and Surgery, March 1, 1860, was the first attempt of the local profession to organize. Dues of \$25 were paid and the salary of the city physician, whose duties were performed one month each year by every member of the academy, was turned over to the society. A lot was purchased a library started and a microscope procured. During the Civil War, however, with many of its members in service, the academy languished until in 1866 it was disbanded. With its reorganization, Feb. 14, 1870, as the Ramsey County Medical Society, it became a component of the Minnesota State Medical Association.

MISSISSIPPI

Dr. Mull Resigns as Dean.—Dr. Philip L. Mull, since 1930 dean of the University of Mississippi School of Medicine, University has resigned effective June 1. Dr. Billy S. Guyton, adjunct professor of minor surgery, has been named acting dean, and Dr. James R. Simms Jr., assistant professor of bacteriology, pathology and clinical diagnosis, assistant to the dean. Dr. Mull will continue as professor and head of the department of anatomy, a position he has held for many years.

NEBRASKA

State Medical Election.—Dr. George W. Covey, Lincoln, was chosen president-elect of the Nebraska State Medical Association at the annual meeting in Omaha, May 14-16. Drs. William P. Wherry, Omaha, and John D. Reid, Pilger, were elected vice presidents and Dr. Claude A. Selby, North Platte, was installed as president.

NEW JERSEY

Honorary Membership in State Society.—Three physicians were made honorary members of the Medical Society of New Jersey at the annual meeting in Atlantic City, May 2. They were Drs. Wells P. Eagleton, Newark; Vanderhoef M. Disbrow, Lakewood, and Philip Marvel, Atlantic City, all of whom were cited for long and distinguished service.

Health at Camden.—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended June 15, indicate that the highest mortality rate (18.3) appears for Camden and the rate for the group of cities as a whole, 10.6. The mortality rate was 12.7 for Camden for the corresponding week last year and was 10.3 for the group of cities. The annual rate for eighty-six cities for the twenty-four weeks of 1935 was 12.3, as against a rate of 12.2 for the corresponding period of 1934. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may increase the death rate.

NEW YORK

Personal.—The University of California conferred the honorary degree of doctor of laws on Dr. George H. Whipple, dean and professor of pathology, University of Rochester School of Medicine, at its commencement exercises, May 18.

New York City

Lectures on Compensation Laws.—The workmen's compensation board of the Medical Society of the County of New York sponsored a group of lectures, the second in a series, at the New York Academy of Medicine, June 19. Speakers were Dr. Raphael Lewy, chief medical examiner, state department of labor, on "Aggravation, Activation and Acceleration of Pre-existing Disease in Its Relation to Trauma"; Dr. George N. Edson, Flushing, "Medicolegal Aspects of the Workmen's Compensation Law"; and Michael Murphy, acting director of the workmen's compensation division of the state department of labor, "Administration of the New Law and the Department of Labor."

Survey of Hospital Needs.—The United Hospital Fund is sponsoring a survey to determine the hospital needs of the New York metropolitan area until 1965. The Carnegie Corporation of New York has made a grant of \$40,000 to finance the study, which is to be completed in the fall of 1936. Five hundred and seventy institutions giving organized care for the sick, including 357 hospitals, will be studied with relation to the needs and facilities for care of the sick through institutions and agencies.

The area to be included in the study consists of the counties of Hudson, Union and Essex and parts of Bergen and Passaic in New Jersey, the counties of Westchester and Nassau, New York, the towns of Stamford and Greenwich, Conn., as well as the five boroughs of the city of New York. The population in this area is now about 10,250,000 and is expected to amount to 18,000,000 in 1965. The study committee in direct charge of the survey includes Drs. Sigismund S. Goldwater, Charles Gordon Heyd, John E. Jennings, Eugene H. Pool, Willard C. Rappleye and Nathan B. Van Etten. George E. Vincent, Ph.D., Greenwich, Conn., former president of the Rockefeller Foundation, is chairman of the survey, David H. McAlpin, Pyle, president of the United Hospital Fund, vice chairman and Dr. Haven Emerson, director of study.

NORTH CAROLINA

Outbreak of Infantile Paralysis—State and local authorities have canceled numerous gatherings scheduled for July in an effort to prevent the spread of infantile paralysis, which has attacked 127 persons in the state since June 1, according to the *New York Times* June 23.

Society News—Dr. Burton W. Fassett, Durham, was elected president of the North Carolina Eye, Ear, Nose and Throat Society, which was organized at a meeting in Pinehurst in May. Dr. James M. Lilly, Fayetteville, is vice president, and Dr. Casper W. Jennings, Greensboro, secretary. The first annual meeting will be held in Greensboro in October.

PENNSYLVANIA

Hospital News—The Bryn Mawr Hospital, Bryn Mawr, has opened a department for the treatment of selected cases of nervous disorders.

Society News—Speakers before the Cambria County Medical Society in Johnstown, June 6, were Drs. Oliver H. P. Pepper and Isidor S. Ravdin, Philadelphia, they discussed "Growing Appreciation of the Importance of Hypotension" and "Recent Advances in Postoperative Treatment," respectively, and held clinics in the afternoon.

Bill Introduced—S. 1627 proposes to authorize the governor to appoint a commission, to be composed of five chiropractors, a member of the senate and a member of the house, to examine and license persons to practice chiropractic. The commission is to report to the general assembly in 1937 a draft of legislation for the regulation of the practice of chiropractic.

Philadelphia

Commencement at Jefferson—Homer P. Rainey, Ph.D., president of Bucknell University, Lewisburg, delivered the valedictory address at Jefferson Medical College, June 7, to a graduating class of 142. His subject was "Relations of General and Medical Training." Clinics for Alumni Day and Ex-Interns' Day were held in Jefferson Hospital, June 5-6, and the annual alumni banquet was held at the Bellevue-Stratford, June 6, with Dr. John B. Lowman, Johnstown, Pa., president of the alumni association, presiding. The graduating class of 1935 presented to the college a portrait of the late Dr. Thomas Cook Stellwagen.

Personal—Dr. Edward Martin, Media, emeritus professor of surgical physiology, University of Pennsylvania School of Medicine, received the honorary degree of doctor of laws at the annual commencement at Temple University, June 13.—The honorary degree of doctor of laws was conferred on Dr. Ross V. Patterson, dean, and Sutherland M. Prevost, professor of therapeutics, Jefferson Medical College, at the annual commencement of Ursinus College, Collegeville.—Dr. Solomon Solis Cohen, emeritus professor of clinical medicine, Jefferson Medical College, received the fifth annual Keneseth Israel Alumni Award May 27.—Dr. Charles R. Turner, dean of the University of Pennsylvania School of Dentistry, received the honorary degree of doctor of science at the annual commencement of the Medical College of Virginia, May 26. Dr. Turner is an alumnus of the school.

Pittsburgh

Prizes for Interns' Case Reports—Dr. John Leo Gedgoud, intern at St. Margaret Memorial Hospital, won first prize in the annual case report contest conducted by the Allegheny County Medical Society with a paper on "Scorbutus in Pittsburgh, An Accident." Dr. Harry Fisher, Allegheny General Hospital, won second prize with a report on "Paraplegic Tetanus Involving Both Lower Extremities." The papers were presented at a meeting of the society, May 21, at which Dr. Francis F. Borzell, Philadelphia, gave an address entitled "What Does the Future Hold for the Medical Graduate?" and Dr. Bertram J. Miles, "A Study of Equilibrium of the Deaf."

TEXAS

Dr. Carter Again Dean of Medical School—Dr. William Spencer Carter, New York, who was dean of the University of Texas School of Medicine, Galveston, from 1903 to 1923, has again been appointed dean to succeed the late Dr. George E. Bethel. Dr. Carter, born in New Jersey in 1869, was graduated from the University of Pennsylvania School of Medicine in 1890. He went to Texas in 1897 as professor of physiology, in 1903 he was made dean, retaining his professorship until his resignation in 1923, when he became associate director of the division of medical sciences of the Rockefeller Foundation.

WASHINGTON

Personal—Dr. Wallace D. Hunt, Seattle, has been appointed health officer of King County, succeeding Dr. Charles L. Dixon, Renton, June 1.

Society News—Drs. Frederick A. Slyfield, Seattle, and Ross E. McPhail, Lakeview, addressed the Grays Harbor Medical Society, Elma, May 15, on the diagnosis and treatment, respectively, of tuberculosis.

In Memory of a Pioneer Physician—Whitman College, Walla Walla, is sponsoring a plan to celebrate in 1936 the one hundredth anniversary of the arrival of Dr. Marcus Whitman in the Northwest and the founding of the first American home in old Oregon Territory by him and his wife, Narcissa Prentiss Whitman. A four-day program is contemplated, with one day devoted to the medical profession and to consideration of Dr. Whitman's work as physician and surgeon.

WISCONSIN

Dr. Middleton Succeeds Dr. Bardeen as Dean—Dr. William S. Middleton, professor of medicine, University of Wisconsin School of Medicine, was named dean of the school by the board of regents, June 21, to succeed Dr. Charles R. Bardeen, who died June 12. A native of Pennsylvania, Dr. Middleton was graduated from the University of Pennsylvania School of Medicine in 1911. He came to the University of Wisconsin in 1912 as a member of the department of student health and has been a member of the faculty since that time except for service during the World War. In 1933 Dr. Middleton was president of the Central Society for Clinical Research and this year became president of the American Association of the History of Medicine at its annual meeting, May 6.

GENERAL

Officers of the Woman's Auxiliary—Mrs. Robert Fitzgerald, Milwaukee, was named president-elect of the Woman's Auxiliary to the American Medical Association at the annual session in Atlantic City, and Mrs. Rogers N. Herbert, Nashville, was installed as president. Vice presidents elected are Mrs. John Bonar White, Atlanta, Mrs. Otis Floyd Lamson, Seattle, Mrs. Elmer L. Whitney, Detroit, and Mrs. Prentiss Willson, Washington, D. C. Mrs. Charles C. Tomlinson, Omaha, is recording secretary, Mrs. Lawrence J. Jones, Wilmington, Del., corresponding secretary, and Mrs. Eben J. Carey, Milwaukee, treasurer.

Medical Bills in Congress—*Bill Introduced* H. R. 8528, introduced by Representative Rankin, Mississippi, proposes to provide domiciliary care and medical and hospital treatment to veterans of the World War and the Spanish-American War and to former members of the Army, Navy, Marine Corps or Coast Guard, who receive compensation or pensions for service connected disabilities. *Changes in Status* H. R. 6995, proposing that all laws in effect on March 19, 1933, granting pensions to veterans of the Spanish-American War, including the Boxer Rebellion and the Philippine Insurrection, their widows and dependents, be reenacted into law, has been favorably reported to the House. H. R. 7260, the so called social security bill, has passed the Senate in amended form.

Society News—The fifth annual convention of the Biological Photographic Association will be held at the Stevens Hotel, Chicago, September 12-14. Information may be had from Ralph P. Creer, chairman of the program committee, Box 266, Hines, Ill.—Dr. Eugene H. Pool, New York, was elected president of the American Surgical Association at the annual meeting in Boston, June 8. The association will meet in Chicago in 1936.—Dr. Albert M. Barrett, Ann Arbor, Mich., was elected president of the American Neurological Association at its annual meeting in Montreal, Canada, June 4. Drs. Howard C. Naffziger, San Francisco, and John Favill, Chicago, were made vice presidents.—Dr. Milton J. Rosenau, Boston, was elected president of the American Association of Medical Milk Commissions at the annual meeting in Atlantic City, June 10-11.

—Dr Catharine MacFarlane, Philadelphia, was chosen president-elect of the Medical Women's National Association at the annual session in Atlantic City, June 10, and Dr Sara Josephine Baker, Stamford, Conn., was installed as president.

Health Projects Aided by Relief Labor—Health and sanitation projects were cited as one of the major contributions of relief labor in a recent summary by Harry L. Hopkins, federal emergency relief administrator. Reviewing the work in forty six states, he pointed out that 553 hospitals have been built and 218 improved or extended. In addition, the following projects were listed: miles of sewers constructed, 2,259; improved 46, miles of water mains constructed, 1,594; improved 70, reservoirs built, 529, improved and cleaned, 218, mosquito-breeding swamps drained, 3,277 150 acres, requiring 28,363 miles of drainage ditches and affecting more than 34,000,000 persons, sewage-disposal plants built, 448, improved, 167, garbage disposal plants built, 45 improved, eight, sanitary privies built, 245,121, improved, 24,087, filter plants built, 15, septic tanks installed, 2,466. These figures are exclusive of work done under the civil works program and do not include the extensive sanitation projects carried on in Puerto Rico and many projects in progress in the United States and not yet reported which would appreciably increase the totals.

Government Services

Positions Open in Civilian Conservation Corps

Eight hundred physicians will be added to the Civilian Conservation Corps under an expansion program, which will increase the corps to 600,000 members, it is announced. At present there are 1,600 physicians in 1,625 camps and military hospitals throughout the country. It is planned to increase the number of camps to 2,917 by August 1. The operation of the camps and the enrolment of physicians are in charge of the various corps area commanders. General medical supervision is under the direction of Major Gen. Charles R. Reynolds, surgeon general of the army. It is the policy of the war department to select physicians for service with the Civilian Conservation Corps who are members of the medical reserve corps, but in some communities part time contract physicians will be employed who may not be members of the reserve corps. Medical department reserve officers training corps units at medical schools throughout the country are being discontinued this month by an act of Congress, which prohibits further expenditure of appropriated funds for their support. Heretofore these units have been the principal agencies through which young physicians have sought commissions in the medical reserve corps of the army. Because of the considerable number of physicians required to provide the medical service for the increased Civilian Conservation Corps, the war department through recent instructions has authorized corps area commanders to accept graduates of class A medical colleges of the 1935 class for enrolment in the medical reserve corps. It is planned to order to active duty several hundred members of the medical reserve corps who desire service with the Civilian Conservation Corps. Recent graduates of class A schools are authorized, under certain conditions, to participate in this active duty. Care will be taken not to employ *interims* before completion of their hospital service. Qualified physicians who desire to enter the medical service of the Civilian Conservation Corps should make application in writing to the commanding general of the corps area in which they reside.

The following is a list of the corps areas, the states included therein and the postoffice address of the headquarters:

First Corps Area Maine New Hampshire Vermont Massachusetts
Rhode Island and Connecticut Headquarters Army Base Boston 9 Mass.
Second Corps Area New Jersey Delaware and New York Headquarters Governor's Island N. Y.
Third Corps Area Pennsylvania Maryland Virginia and the District of Columbia Headquarters 311 St. Paul Place Baltimore Md.
Fourth Corps Area North Carolina South Carolina Georgia Florida Alabama Tennessee Mississippi and Louisiana Headquarters Fort McPherson Ga. Mail address Oakland City Station Atlanta Ga.
Fifth Corps Area Ohio West Virginia Indiana and Kentucky Headquarters Fort Hayes Columbus Ohio
Sixth Corps Area Illinois Michigan and Wisconsin Headquarters 1819 West Pershing Road Chicago Ill.
Seventh Corps Area Missouri Kansas South Dakota Arkansas Iowa Nebraska Minnesota and North Dakota Headquarters Baird Building Omaha Neb.
Eighth Corps Area Texas Oklahoma Colorado and New Mexico Headquarters Fort Sam Houston San Antonio Texas
Ninth Corps Area Washington Oregon Idaho Montana Wyoming Utah Nevada California and Alaska Headquarters Presidio of San Francisco Calif.

Foreign Letters

LONDON LETTER

(From Our Regular Correspondent)

June 1, 1935

The British Graduate Medical School

The opening of the new British Postgraduate Medical School by the king was described in a previous letter. For the first time graduate teaching is centralized in this country in a suitable hospital, staffed in every way necessary for the purpose. The hope has been expressed that London may become the world's principal center for graduate teaching. The position of certain continental countries that enjoyed a world reputation both as centers of research and of teaching has been damaged by the World War and still more by the destruction of liberty and the persecution of scientists which followed that catastrophe. Instruction in clinical medicine is provided by appointments to the wards of graduate students as clinical clerks for periods of three or more months. Intensive courses for physicians, lasting two weeks, will be given frequently. In these a disease or group of diseases will be demonstrated in their various aspects—clinical, pathologic, radiologic. It is also proposed to arrange a series of lectures and demonstrations one day in the week for London physicians. Graduates engaged in investigation who require clinical material can be accommodated in small numbers. Visitors for short periods will be welcomed and arrangements made for them to see whatever work they desire. Visitors from abroad who wish to follow intensive studies or to learn English methods will find their needs supplied.

The teaching is organized in four departments—medicine, surgery, obstetrics and gynecology, and pathology. These are each directed by fulltime professors who are well known teachers and they are assisted by a staff, many of whom specialize in subordinate subjects. Eminent teachers in other medical schools will also visit the hospital at regular intervals as consultants and at other times when required. It is also hoped that the services of distinguished visitors to London from the country or from abroad may be obtained and that they will take charge of wards for a time and engage in the routine work of the school. The organization is in some ways comparable to the teaching "units" recently formed in the medical schools, but for graduate teaching nothing comparable to it has existed before in this country.

The Chatter of Food Faddists

Addressing the annual conference of the Scottish National Health Visitors Association, Prof. E. P. Cathcart, F.R.S., the well known dietitian, said that all the chatter about food which they hear today had a bad effect in making sensitive people become food conscious and then food faddists, food fanatics and finally missionaries. Much nonsense was talked about calories, calories were only a unit of heat. There was no hidden value in them. Emphasizing the importance of an adequate amount of proteins, carbohydrates and fats in the diet, Professor Cathcart said that as regards fat they would find a direct relation between its consumption and economic status. The more money available, the greater the amount of fat consumed, and at no time in the history of the human race was so much fat consumed as now. The increase had taken place largely in the last thirty years. Tuberculosis was one of the few diseases that responded to improved nutrition. He was certain that there was much malnutrition among widows and unmarried daughters and men who had once been in comfortable circumstances and were now eking out a meager existence on a minute income without saying a word. As shown in previous

letters, misleading political propaganda has been used to suggest that there is prevalent malnutrition due to insufficiency of the dole for unemployment. It is noteworthy that Professor Cathcart's example of malnutrition is, on the contrary, in the class that is taxed highly to finance the dole and other social services.

Psychoneurosis as a Cause of Incapacity Among Insured Persons

A regional medical officer of the department of health for Scotland, Dr J. L. Halliday, has published in the *British Medical Journal* the results of an inquiry into 1,000 consecutive records of insured persons (excluding pregnant and puerperal women) certified as unfit for work, with a view to determining the proportion incapacitated by psychoneurotic disorders. He found that this amounted roughly to a third (36 per cent in the case of women and 31.7 in men). There was a slightly higher incidence of psychoneurosis among the unemployed than the employed, which increased with the duration of the unemployment. Thus the percentage incidence among those who had been unemployed for less than three months was 25.7, less than the incidence (32) among those who became incapacitated during employment. But with lengthening of unemployment the incidence increased to reach a maximum of 41.5 per cent in the period six to twelve months. There appears to be a short period of a sense of release and holiday freedom, then gradually increasing anxiety with loss of mental equilibrium and finally, after several years, adaptation takes place to a new and debased level of life.

In an exhaustive survey of the effects of unemployment Sir George Newman, chief medical officer of the ministry of health, stated that there is no medical evidence of any general increase in physical impairment, in sickness, or in mortality as a result of economic depression or unemployment. It would thus seem that unemployment influences the mind rather than the body.

The Manufacture of Synthetic Drugs

Before the war practically all the synthetic drugs used in Great Britain came from Germany. Since that catastrophe we no longer depend on that country to the same extent for the manufacture of drugs or dyes. In the report of the Chemistry Research Board, just issued by the department of industrial and scientific research, the first complete survey of the work carried out in the chemical research laboratory during the ten years of its existence is described. Several firms have made arrangements for members of their staffs to be attached to the laboratory in order to learn the new methods of technique developed there. The board has arranged for the preparation of synthetic chemicals of the types likely to be useful in the treatment of disease, and, by cooperation with the Medical Research Council, to have them tested for chemotherapeutic effects. This arrangement covers not only chemicals that are produced in the chemical research laboratory but also those produced by workers in universities who are assisting in this branch of the work. Although this work has a medical objective, it is a joint field in which the chemist can render valuable aid, as, apart from the alleviation of suffering, the production in this country of synthetic drugs has an important industrial and imperial significance.

Graduate Courses for Ship Surgeons

The Seamen's Hospital Society of Greenwich has, at the instigation of the British Medical Association, placed its resources connected with the London School of Clinical Medicine and the London School of Hygiene and Tropical Medicine at the disposal of ship surgeons for graduate work. The society controls the Seamen's Hospital of Greenwich, where courses for ship surgeons are held as follows: Part 1 Ships' hygiene. Part 2 Tropical medicine and hygiene. Part 3 Refresher courses in clinical subjects. Thus ship surgeons are able to

study cases drawn from the very class with which their daily work is concerned. They are specially trained in the treatment of surgical emergencies, the treatment of fractures and the prevention of protracted disability, the expediting of movement in quarantine, the differential diagnosis of tropical disorders, the discrimination of spurious from genuine claims in respect to injury and dealing with the special problems of hygiene arising on board ship. Unfortunately, though ship surgeons are ready enough to take advantage of the facilities provided, the great shipping companies have not seen their way to support the scheme—doubtless owing to the financial stress of this industry. The pay of ship surgeons is not sufficient to allow them to undertake these courses entirely at their own expense.

Preoperative Radiography of Acute Intestinal Obstruction

This has been the subject of a general discussion at the Dec. 19, 1934 and Feb. 20, 1935, meetings of the Société de chirurgie of Paris. Moulouquet and Rousset first reported their experiences in seventeen cases in which plain roentgenography alone was employed to confirm the diagnosis and to localize the seat of the acute obstruction. The ingestion of an opaque medium is strongly contraindicated in these cases. The best films were obtained in the upright position. A marked collection of gas in the colon indicated obstruction in this portion of the alimentary tract. Normally there is no gas to be seen in plain films of the small intestine, so its presence is pathognomonic of obstruction there. Such manifestations are not seen in reflex ileus accompanying biliary or renal colics. Often the roentgenographic evidence is to be elicited at an earlier period of the obstruction than are the clinical signs. One cannot distinguish between a septic ileus due to peritonitis and one due to mechanical causes. In the latter form, localization of the exact level at which the obstruction has occurred is difficult on plain films. Generally, the point at which the gas is absent corresponds to the level of the obstruction. As to the nature of the obstruction in acute ileus, the only form that can be diagnosed is that due to an impacted gallstone. Roentgenography before operations for acute ileus of the large intestine is of much use in determining the level at which a colostomy should be made.

Mondor and Duval did not share the enthusiasm of Moulouquet. Mondor emphasized that the short time required to make a preoperative roentgen examination was amply rewarded by the rapidity with which one could operate, if the level of the obstruction was known. He prefers the opaque enema to dependence on plain films. If barium is used, only small amounts should be employed and much pressure must be avoided. The opaque enema enables a differential diagnosis to be made between a volvulus of the sigmoid and an obstruction due to a neoplasm of the colon. The interpretation of plain films is so difficult that Mondor has abandoned the method as a diagnostic aid in acute ileus.

Duval, Béclère and Porcher agreed with Mondor's criticism of plain roentgenography because gas may be present in variable amounts in the small intestine under normal conditions. They believe that roentgenography with an opaque enema is almost indispensable in acute ileus. One cannot distinguish a reflex ileus complicating biliary or renal colic from a mechanical obstruction on the plain film. In the absence of an opaque enema, one cannot tell whether the obstruction is in the large or the small intestine. Aside from ileus due to a gallstone or to stenosis of the colon, it is impossible to determine in adults, even with an opaque enema, the cause of an obstruction. One

ought to employ roentgenography (with opaque enema) as a routine measure in all cases of acute intestinal obstruction.

At the February 22 meeting, Professors Gosset and Ledoux-Lebard added their experiences to those of others reported at previous meetings of the society.

No contraindication to the use of the method exists, and the slight delay is well repaid by the abbreviation of the operative procedure. A plain film is taken as a preliminary measure to exclude obstruction by a gallstone. This is followed by a barium enema under fluoroscopic control.

Slides were shown of three cases in which the barium column attained only the level of the descending colon, thus greatly facilitating the determination of the level at which colostomy should be done. In a fourth case, the opaque enema stopped at the cecum, thus revealing the location of the obstruction before operation. In two other cases, the ileus followed appendectomy and the obstruction could be accurately located as being in the small intestine. In one of the last two cases, a child, aged 6 years, an intussusception could be readily excluded by the opaque preoperative enema.

Another interesting case of how preoperative roentgenography can aid the surgeon in the diagnosis of the seat of an acute obstruction was reported by Paris at the March 12 meeting. A man, aged 48, had an attack of diffuse acute abdominal pain followed by vomiting, four days before admission to the hospital. He had been in good health up to the onset of the present illness. A barium enema was given under fluoroscopic control and under low pressure. The entire colon was seen to be filled by the opaque enema so that a diagnosis of obstruction of the small intestine could be made.

The laparotomy, immediately after the roentgen examination, revealed a volvulus of a loop, about 50 cm in length of the small intestine. The volvulus accompanied a torsion of the omentum. The latter was resected and the volvulus reduced. Recovery followed.

Three final papers, one by Michel-Bechet, one by Fournier and Depreuil, and another by Moulouguet, who was the first to reawaken interest in the subject, seem to be the final ones in the discussion. Michel-Bechet has employed the method in twelve cases, two of which were of particular interest. In one case, plain films (without barium enema) revealed the presence of a sigmoid-shaped coil of small intestine near the stomach.

A diagnosis was made of obstruction and at the operation a coil of small intestine was found strangulated in the foramen of Winslow.

Fee-Splitting and the Income Tax Office

According to a law passed July 20, 1934, every physician is required to state, in his annual declaration of income from professional work, the amount paid to colleagues, if said sum is in excess of 1,000 francs (about \$65). An interesting discussion of the new law by R. Massart appears in the March 17 *Concours médical*. Surgeons will be obliged to state how much was received for an operation and how this sum was distributed. The medical man who referred the patient to the surgeon will be obliged to state in his income tax schedule the sums received from the surgeon. Massart states that, as the result of this new law, the clandestine division of fees will disappear. Efforts have been made by various medical organizations to suppress the evil, but none will be as effective as the new law. According to the latter, whenever a physician or surgeon sends separate bills for services, or a joint bill in which the amount to be received by each one is stated, no special declaration of such amounts is necessary in the income tax schedule. On the other hand, if the surgeon receives the entire fee, the law requires that the names and amounts paid to each medical man who referred the respective patient must be stated. Otherwise the surgeon will be obliged to pay the

income tax on the total amount received. A case is cited in which the tax office had knowledge of a relatively large sum paid as fees to a surgeon. In the latter's income tax schedule only half of the amount was declared as having been received. The internal revenue department immediately demanded payment on the entire amount paid to the surgeon, who in turn would be obliged to state to whom he had paid the other half so that the collector could proceed to collect taxes on these fees. Rather than disclose the names of the physicians who referred the patients and the amounts paid, the surgeon paid the tax on the original amount himself.

Such settlements will not be considered legal in the future, hence the new law will compel all members of the medical profession to state, in a special book open to inspection by the internal revenue collector, a detailed account of their receipts and expenditures.

Massart states that the medical profession is being subjected to what may appear to be an unjust persecution by the authorities, because the filing of income tax schedules was not regarded as seriously as it demanded by physicians in the past. The young practitioner is taxed relatively too high in comparison with the tax paid by older men. The latter are especially asked by Massart to be more exact in stating their incomes and expenditures. The law is in force and must be respected, lest still more objectionable requirements than keeping a daily account will be required. The new law will have more effect in checking the obnoxious and widespread evil of fee-splitting than all the threats of expulsion made by organized medicine.

Psychopathic Patients and Race Hygiene

Prof H. F. Hoffmann, psychiatrist of Giessen, recently pointed out that the peculiarities of psychopathic patients are in the main of hereditary origin. Of that fact research on twins has furnished unequivocal examples. There are cases known in which enzygotic twins reacted to external difficulties, independently of each other, with the same neurotic symptoms. There are also many instances in which the attitudes of psychopathic enzygotic twins toward life as a whole are identical or at least surprisingly similar. As a rule, psychopathic patients are the offspring of psychopathic parents—at least on one side, if not on both sides. In the event of psychoses in the ancestors, the inherited defects appear in certain cases to be more dominant than in the average person. Thus, schizoid psychopathic patients reveal striking evidence of hereditary influence, while cycloid and epileptoid psychopathic patients frequently show hereditary tendencies traceable to circular insanity or epilepsy. Of late, it has been asserted also that hereditobiologic relations exist between psychopathy and neurologic disorders. If one divides the psychopathic patients into two groups according to their asocial and antisocial behavior, it will be observed that those who are abnormal socially show to no inconsiderable degree the hereditary influence of socially abnormal psychopathic persons and persons with criminal tendencies. There are as yet no comprehensive studies on the posterity of these two groups. But from the general impressions one gets it may be said that the abnormal psychopathic patients have, as a whole, an unsavory posterity. Importance is ascribed also to the fact that socially abnormal psychopathic persons usually mate with persons who are of an inferior type mentally, whereby the frequency and the degree of social degeneration in the offspring are, in many instances, greatly increased. Hoffmann has carried out extensive hereditobiologic researches on these groups. Particularly dangerous for posterity is the type of unstable, undisciplined, irascible and brutal

psychopathic patient Among their children one observes, in addition to psychopathy and criminality, grave types of imbecility, schizophrenia and epilepsy According to these researches, race hygiene, from the social point of view, should emphasize more particularly in psychopathic patients the absence of social worth and antisocial influence

Immunization Against Diphtheria

The increased incidence of diphtheria in certain regions of Germany is causing anxiety Recently the federal bureau of health expressed its views on the question of diphtheria immunization. According to its conception, diphtheria immunization is still in the experimental stage, so that a final decision in regard to its value cannot be rendered as yet However, the report states, the results secured in foreign countries and also in Germany are very encouraging and justify a continuation of the inoculations A general introduction of diphtheria immunization is, on the other hand, unacceptable For the present, its use should be confined to regions in which the morbidity and the mortality from diphtheria are particularly high In regions in which general immunization is thus indicated, an endeavor should be made to include as many children as possible but without making protective inoculation compulsory As far as can be ascertained, the inoculation is harmless, and the reactions are, for the most part, slight In order to avoid any possible chance of untoward effects resulting from inoculations against diphtheria, children with acute or chronic diseases, particularly tuberculosis, should be exempted, for the time being The duration of the immunization, which is considerable after from eight to ten weeks, and fully developed after about three months, is not yet known with certainty The inoculation of children aged from 1 to 8 years may properly be accomplished with diphtheria anatoxin (toxoid), older children may better be given toxin-antitoxin vaccines, as they are more easily borne The vaccine materials used in Germany are controlled by the central government In collaboration with certain eminent pediatricians, the federal bureau of health has published a leaflet and also a pamphlet, containing detailed information on the subject of diphtheria immunization

Fatigue, Sleep and Restoration

Prof. L. R. Müller, clinician of Erlangen, who, for many years, has made a special study of the biology and the clinical aspects of the central nervous system, recently called attention to the connections between fatigue, sleep and the restoration process in general One must distinguish between sense of fatigue and the local sensations that, following severe bodily exertion, are noted in the joints, the tendon sheaths and the muscles, being due to the overwork demanded of these tissues The sense of fatigue that induces one to quit work and seek sleep is not associated with local sensations but is due rather to the mental observation that the work is no longer progressing satisfactorily In considering the general sense of fatigue, one must pass, therefore, from the neurologic to the psychologic aspect Recent researches of the Zurich pharmacologist Cloetta and his co-workers have revealed that, with the stimulation of the neuromuscular apparatus, cations (chiefly calcium and potassium) pass from the nerves and from the muscles into the blood serum and that, as a result of sleep, a remigration of these cations into the neuromuscular substance occurs Thus, for the first time, an attempt has been made to clarify the physical and chemical processes that lie at the basis of sleep and of stimulation of the muscles There is no doubt that bodily fatigue cannot be completely overcome by rest or by the ingestion of food but only by sleep sleep alone leads to a complete recovery or restoration

Nearly all infectious diseases are associated at first with a marked feeling of weariness that makes rest in bed imperative, likewise many disturbances of the internal secretions (Addi-

son's disease, hyperthyreosis) and diseases of the blood Fatigue in asthenic persons who are constantly worried about their health may be of mental origin An attempt to control fatigue with caffeine involves a delay only in the onset of the fatigue, the fatigue is not actually overcome.

Mortality Among the New-Born

Prof. P. W. Siegel has published a statistical compilation on early mortality of the new-born in the East Prussian Landesfrauenklinik Insterburg For purposes of comparison there were available the official statistics on the living births of East Prussia in 1931, the 4,458 living births of midwife practice, and finally the 4,446 living births in the aforementioned clinic. The statistics on early mortality for East Prussia (figured for the first fifteen days of life) revealed a mortality of 3.3 per cent, in midwife practice (including the operative obstetric interventions of the practitioners) of 3.4 per cent, and in clinical practice of 1.3 per cent. According to Siegel, it may be assumed that the other obstetric clinics secure the same results It is evident, therefore, that the success of clinical obstetrics, as compared with domiciliary practice, is not inconsiderable. For purposes of comparison, the results of various forms of obstetric practice are given in detail early mortality following the use of the forceps was, in general practice, 6.9 per cent (in the hospital, 1.6 per cent), after version, in general practice, 10.7 per cent (in the hospital, 0 per cent), after manual aid, in general practice, 11.4 per cent (in the hospital, 7.5 per cent), after cesarean section, in general practice, no operations (in the hospital, 3.5 per cent) It is evident, therefore, that the conditions for operative births in the hospital are much more favorable than in general practice, although the hospital has more cases of contamination than are found in general practice These observations are particularly interesting in connection with the recent recommendation of the minister of the interior that confinements be carried out more frequently in the home than has been done in the past

MADRID

(From Our Regular Correspondent)

May 17, 1935

Political Control of Public Health Work

Dr. Victor Cortezo, head of the department of public health, in a lecture recently delivered before the Academia Nacional de Medicina, said that public health work in Spain before 1899 was practiced only by physicians of the ports having as a director an administrator with an office in the ministry of interior Drs. Cortezo, Pulido and Gimeno's efforts to extend the public health work at that time failed The development of public health work in Spain since 1899 may be divided into three periods The first period began with an outbreak of plague in Portugal in 1899, which forced the Spanish government to cooperate with the group of public health workers, who at that time had a very small organization The advances made during the period up to 1910 included the organization of the central department of public health, the adoption of regulations on national and international sanitation, and the establishment of the Instituto Nacional de Higiene by Drs. Cajal and Cortezo The second period, from 1910 to 1923, began with the outbreak of cholera in Russia and its spreading to the northern regions of Italy and to Germany, Austria, Hungary, Turkey, Rumania and France. In this period the sanitarians were very active and their efforts and those of the government restricted the epidemic of cholera to a few cases that occurred in the towns of Vendrell and La Riera Then the personnel that had been trained to fight the cholera epidemic were used to fight typhus in Gijón, plague in the Canary Islands, Malaga and Barcelona and other local epidemics in several provinces The third period, from 1923 to 1935 was characterized by the organization of several health centers for the care of the sick and the isolation of persons

suffering with plague. These centers were either aided or supported by the state, the county or the provinces. They functioned successfully during the first few years while support was given to them, but the discontinuation of governmental support resulted in either their closure or the transfer of the center to the state, to be used for other purposes of public welfare. A case can be cited. The regional leprosarium of Andalusia, which was given at the beginning to the provincial committee of deputies of Granada, is now used as an asylum for children and the problem of isolating the lepers of Andalusia is still unsolved. At present the national budget allows three times as much money for public health as it did during the time of the kingdom. Departments and branches of the public health administration have been established even in distant small towns. Owing, however, to the fact that many of the persons appointed to health positions are not trained sanitarians, the work in the field is not as satisfactory as it should be. The fact that the field sanitary work is controlled by the state has resulted in the disappearance of some health centers, such as the Liga contra la tuberculosis and the Liga contra el cancer. The latter used to provide Madrid with about 200 beds for patients with cancer. The public health work at present is greatly affected by political and economic conditions. Formerly the public health department had a general director. Later he was called sub-secretary of public health and still later he was called head of the public health in the ministry of labor and public health which departments now are merged. No more are sanitarians consulted on the preparation of public health regulations, they first know of them only after their publication in *La Gaceta*, the official journal.

New Hospital Opened in Madrid

For a long time most of the hospitals in Spain were Catholic, having a chapel for religious services, a chaplain paid by the government, and sisters for the care of the patients. During the last few years, most of the hospitals have functioned under a different system. In many of them, nurses have been substituted for the sisters. A new hospital, in which the standards of the Catholic hospitals of the United States were followed, was recently opened. Dr. Baldomero Castresana and the bishop of Madrid collaborated in the organization of this hospital. There are now sixty beds ready for patients. Dr. Enrique de Salamanca, the director of the laboratory, is now in the United States visiting laboratories and research centers to study the latest improvements. The expenses of the hospital are supported by donations from Catholics in any country as well as by a percentage of the income of the Catholic churches in Madrid. Priests who help support the hospital are given in turn the privilege of providing free medical care to a certain number of poor patients in the hospital. The hospital is well equipped and meets all the modern requirements of a good hospital.

Eighth Centennial of Birth of Maimonides

Ceremonies were recently held in Córdoba and in Madrid to celebrate the eighth centennial of the birth of Maimonides, the Spanish rabbi and philosopher. Drs. Govanes and Garcia del Real in addresses, reviewed his history in connection with the development of medicine. During the twelfth century, Arabic Spain had seventy public libraries and seventeen centers for higher education. Great devotion to studies was necessary then to secure an education. Maimonides drank deeply at the fountains of knowledge, but religious persecutions arose and Maimonides left Spain for Africa. His contact with the Greek and Roman literature influenced his medical writings in which he followed the galenic and hippocratic traditions. Maimonides was highly accomplished. His interpretation of the Bible and of the Talmud led his people to consider him a saint. When he died in 1204, he was physician to the sultan of Egypt and the

head of the Jewish people at Cairo. Some of his books in the libraries of Spain are *Alimentos prohibidos*, *Venenos y sus remedios*, *Aforismos de medicina*, *Canones de medicina practica*, *Tratado de higiene*, *El coito*, *Causas de las enfermedades*, *La curacion del asma*, *Dieta*, *Schmorich Paraquim*, *Libro del conocimiento* and *The Guide for the Perplexed*. The last mentioned book was translated from the Arabic into the English language by Friedlander and published by E. P. Dutton & Co. of New York.

Personals

Dr. Enrique Suñer, professor of diseases of children to the Faculty of Medicine of Madrid and organizer of the Escuela Nacional de Puericultura, who some time ago was removed as director of the school, a position which he had had for a long time, has been reappointed to the same position by a decision of the supreme court, to which he appealed. His appointment received general approval.

April 26, 1935

Priority of Discovery of Cause of Tsutsugamushi Disease

Tsutsugamushi is a serious disease, which has been widely known more than half a century, and thirty years or more has been given by many investigators to discover its cause. Not a few of these workers have fallen victims to the disease. The question of priority in the discovery of the cause was once more an issue in the annual meeting of the Japanese Pathologic Society held in April in the Nigata Medical College. Prof. Dr. Ogata of the Chiba University, a bacteriologist, read a paper on the question. He insisted that he discovered its cause in 1927 to be *Rickettsia tsutsugamushi*. His work has since then been confirmed by others. In 1930 Dr. Nagayo, now president of the Tokyo Imperial University, and then the chief of the Infectious Disease Research Institute, with his colleagues, borrowed the germ from Dr. Ogata and succeeded in detecting the organism, but by methods different from the method of Ogata. They for the first time named it *Rickettsia orientalis*. In 1931 Prof. Dr. Kawamura of the Nigata Medical College succeeded by a new method in detecting the same cause, in the next year Prof. Dr. Saibe of the same institute also was successful but he unhappily fell a victim to the disease. In recognition of their work those four researchers were awarded prizes. When Ogata discovered the cause in 1927, he did not give it a name. He considered this research so important that he assumed a cautious attitude. But suddenly Dr. Nagayo named it without referring to Ogata's discovery. Discovery and naming a discovery are quite different. In 1923 Sellards obtained a micro-organism from a case of this disease and named it *Rickettsia nipponica* mistaking that micro-organism for its true cause. So in Otto's writings in 1934 it is said that the cause of tsutsugamushi is Sellard's *Rickettsia nipponica*, which is of course a mistake. In 1931 Professor Kawamura found an *akamushi*, which means almost the same thing as "*Rickettsia*," and so gave the name of *Rickettsia akamushi*, but in 1934 this name was again changed to *Rickettsia tsutsugamushi-orientalis* (Nagayo et al.). This long name cannot be said to be proper and satisfactory.

Dr. Ogata declares that he would not compromise so far as the discoverer is concerned insisting that he is entitled to priority. At the same time he hopes that the name of the causative agent will soon be decided, so that mistakes may be avoided at home and abroad. He proposed the name *Rickettsia tsutsugamushi*, but if any one objects to that it might be called *Rickettsia tsutsugamushi s. kedani*, as the word "*kedani*" has long been associated with this disease. On the other

hand, the members of the Infectious Disease Research Institute, of which Dr. Nagayo was long the chief, believe that the true cause was first detected by them, and to prove it, Ogata in 1931 was awarded the "Wihew" prize of the pathologic society. The paper made public by the members of the institute in 1924 is said by them to be the first valuable literature on its cause, and that paper decidedly settles the question of priority. Dr. Ogata says it has no connection with the discovery of the cause and is a mere report of the progress of their research.

Memorial to Dr. von Siebold

The first physician who introduced European medicine into Japan by teaching medical science and treating patients was Dr. von Siebold, a German. He was the first who taught Japanese doctors clinically. To celebrate this valuable assistance an exposition is being held in Tokyo at the science museum. Von Siebold's efforts covered so many branches of science that medicine was only a small part of them. In 1820, at the age of 28, after graduating from a German university, he came to Japan as a ship doctor of the Dutch East India Company. He was keenly interested in teaching earnest students about European civilization. The methods taught by him opened the eyes of old-fashioned students. In the present memorial exposition there are exhibited more than 300 publications, which were borrowed from his native country, and more than 400 collected for the purpose in this country. Among others, are shown his valuable works "Flora Japonica" and "Fauna Japonica." As for his medical papers, only a few are kept, to the great regret of Japanese physicians. From those few papers it is known that he gave his followers many questions to solve in a scientific way, on the other hand, he was much interested in Japanese acupuncture, and he translated a work on this subject into German.

Native Population Decreasing in the Yap Islands

The Kanakas, the inhabitants of the Yap Islands, which are now under the mandatory administration of Japan, will become extinct in thirty years, says Ihara of the sanitary bureau of the Home Office, after an inspection tour of those islands. He gave the following report concerning the cause of the rapid decrease of the Kanakas. Widespread gonorrheal infections, tuberculosis, dysentery and typhoid, brought by immigrants from more civilized nations, are the chief causes of the rapid decrease of births and the increase of deaths. The islanders are much averse to any new medical treatment or even examination. They seem to have no idea of birth control. There are many who attribute pregnancy to the gods. Intemperance and overwork during pregnancy seem to cause much abortion. Poor sanitation, with almost no idea of cleanliness or ventilation, is also an important cause. The prohibition of drinking resulted in idleness, for they formerly worked so as to be able to buy liquor, whereas now they do nothing to develop their bodies. They are also ill nourished. There is need for the authorities to inculcate some idea of sanitation and prevention of disease.

The Period of Pregnancy

Dr. Obata, director of the Hamada Hospital in Tokyo, read a paper on the period of pregnancy at the spring meeting of the gynecologic society. The old theory that pregnancy continues for 280 days is incorrect. According to his report, only 38 per cent of pregnant women are delivered in 280 days. Of 10,000 pregnant women who came to his hospital, the pregnant period was from twenty-nine to fifty weeks. He found that the period usually was from 263.9 days to 297.3 days. The weight of the baby usually was between 2,475.9 and 3,344.7 Gm. About thirty women who happened to know exactly the day of conception stated that the period was between 288 and 233 days. Obata concluded that the period of pregnancy is indefinite and depends chiefly on the individual.

Marriages

FRANK LESLIE MILLIGAN, Jefferson City, Tenn., to Miss Mildred Osborne of Leechville, Ark., in Manila, Ark., June 4.

WYCLIFFE CHARLES JACKSON, Jenkin Jones, W. Va., to Miss Mary Stuart McCallum of Rowland, N. C., June 1.

GEORGE MIDDLETON IRWIN, Lewistown, Pa., to Miss Mary Elizabeth Dunbar of Washington, N. J., May 11.

DELMAR O. RHAME JR., Clinton, S. C., to Miss Henrietta Toole of Johnston, June 5.

FRANK E. ADAIR to Mrs. Marion Hopkinson Brooks, both of New York, May 29.

Deaths

Clarence St. Clair Drake, Jacksonville, Ill., Chicago Homeopathic Medical College, 1891, Chairman of the Section on Preventive Medicine and Public Health of the American Medical Association, 1918-1919, and Member of the House of Delegates in 1920, member of the American Psychiatric Association, statistician for vital statistics, Chicago Health Department, 1895-1909, member, secretary and executive officer of the Illinois State Board of Health, 1914-1917, director of public health for Illinois, 1917-1921, educational field director of the American Public Health Association, 1925-1929, since 1929 managing officer of the Jacksonville State Hospital, aged 65, died, June 2, of heart disease.

William Jackson Merrill, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1902, associate professor of orthopedics, University of Pennsylvania Graduate School of Medicine, member of the American Orthopedic Association, fellow of the American College of Surgeons, served during the World War, orthopedic surgeon to the Children's, Misericordia and Jewish hospitals, Philadelphia, Children's Seashore House, Atlantic City, N. J., the Williamsport (Pa.) Hospital, the George F. Geisinger Memorial Hospital, Danville, and the Lock Haven (Pa.) Hospital, aged 66, died, May 10, of pneumonia.

Henry Edward Oesterling, Winter Park, Fla., University of Pennsylvania Department of Medicine, Philadelphia, 1897, member of the West Virginia State Medical Association and the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, formerly on the staff of the Ohio Valley General Hospital, Wheeling, W. Va., aged 62, died, May 22, in the Graduate Hospital of the University of Pennsylvania, Philadelphia.

Joshua George Ross Manwaring, Flint, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901, member of the House of Delegates of the American Medical Association in 1930, past president of the Genesee County Medical Society, one of the founders and fellow of the American College of Surgeons, formerly on the staff of the Hurley Hospital, aged 57, died, April 17, of angina pectoris.

George Bronson Philhower, Nutley, N. J., University of the City of New York Medical Department, 1886, member of the Medical Society of New Jersey, past president of the Essex County Medical Society, for many years president of the board of health of Nutley, member of the board of education, on the staff of the Presbyterian Hospital, Newark, aged 72, died, May 23, in St. Barnabas Hospital, Newark.

Brace Whitman Paddock, Pittsfield, Mass., Columbia University College of Physicians and Surgeons, New York, 1904, fellow of the American College of Surgeons, past president of the Berkshire District Medical Society, on the staff of the House of Mercy Hospital, aged 56, died, May 22, of arteriosclerosis.

Edward W. Boyer, Waterville, Me., University of Vermont College of Medicine, Burlington, 1887, member of the Maine Medical Association, past president of the Kennebec County Medical Society, formerly member of the board of education, on the staff of the Sisters Hospital, aged 70, died, May 6.

Clinton LeRoy Pugmire, Ogden, Utah, Northwestern University Medical School, Chicago, 1932, aged 30, died, April 21, in the Dee Memorial Hospital, of streptococcal septicemia following a small wound on his finger received while attending a patient.

Thomas Elmer Roberts @ Oak Park, Ill., Chicago Homeopathic Medical College, 1888, Rush Medical College, Chicago, 1897, veteran of the Spanish-American War, aged 70, died suddenly, June 9, of heart disease while playing golf at El Paso, Texas

Hubert De Laserre Spence, Painesville, Ohio, Homeopathic Hospital College, Cleveland, 1885, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1897, aged 76, died, May 5, of coronary thrombosis

Zach Godfrey Smith, Marion, S. C., Vanderbilt University School of Medicine, Nashville, Tenn., 1889, member of the South Carolina Medical Association, aged 65, died, April 20, in the McCord Infirmary, Florence, of bronchopneumonia

Edward Maurice De Castro Jr. @ Brooklyn Long Island College Hospital, Brooklyn, 1898, on the staffs of the Calcdoman and Harbor hospitals and the Brooklyn Home for Consumptives, aged 55, died, June 2, of heart disease

Mary Elizabeth Bradford, Newburgh, Ind., Woman's Medical College, Chicago, 1887, formerly a medical missionary in Persia, aged 77, died, June 10, in the Deaconess Hospital, Evansville, following an operation for appendicitis

Louis Philip Rich @ Fredericksburg, Iowa, Keokuk Medical College, College of Physicians and Surgeons, 1903, served during the World War, aged 59, died, May 5, of angina pectoris and arthritis

Benjamin Earle Bostwick @ New Milford, Conn. Long Island College Hospital, Brooklyn, 1890, past president of the Litchfield County Medical Society, aged 68, died, May 26, of coronary thrombosis

Arthur Lloyd Chapman, Rahway, N. J., Meharry Medical College, Nashville, Tenn., 1931, aged 31, died, April 12, in the Bonnie Burn Sanatorium, Scotch Plains, of pulmonary tuberculosis

John Joseph Gaines, Excelsior Springs, Mo., University Medical College of Kansas City, Mo., 1893, member of the Missouri State Medical Association, aged 73, died, April 5

Elizabeth Garlick Smith, Bridgeport, Conn., United States Medical College, New York, 1883, aged 86, died, March 18, of diabetes mellitus and gangrene of the left foot and leg

Hugh Nutting, Washington, D. C., George Washington University School of Medicine Washington, 1906, aged 57, died, March 12, of coronary occlusion and arteriosclerosis

Judson J. Shultz, Delphi, Ind., Eclectic Medical Institute, Cincinnati, 1879, member of the Indiana State Medical Association, aged 79, died, May 21, of heart disease

Clarence Alfred Trainor, Los Angeles, Northwestern University Medical School, Chicago, 1910, aged 51, died, suddenly, May 17, of coronary occlusion

Llewellyn Henry Johnston, Milwaukee, University of Toronto (Ont.) Faculty of Medicine, 1907, aged 62, died, May 3, of cerebral hemorrhage

Fred Sumner Smith, Chester, Conn., Yale College Medical Department, New Haven 1882, aged 79, died, April 24, of carcinoma of the rectum

Thomas E. Stucky, Milroy, Ind., University of Louisville (Ky.) School of Medicine, 1874, aged 82, died, April 30, of cerebral thrombosis

William Converse Phillips, Zephyrhills, Fla., Boston University School of Medicine, 1896, aged 79, died, May 7, of angina pectoris

Andrew William Imrie, Los Angeles, McGill University Faculty of Medicine, Montreal, Que., Canada, 1879, aged 78, died April 13

Max J. Stern, Atlantic City, N. J., Jefferson Medical College of Philadelphia, 1885, aged 73, died, April 25, of bronchopneumonia

Marcus Spiro @ Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1893, aged 70, died, April 21, of myocarditis

Ella Mansfield Caryl, Los Angeles California Eclectic Medical College, Los Angeles, 1914, aged 74, died, April 3

Alice Morrison Swayze, Los Angeles, California Medical College, San Francisco, 1895, aged 77, died April 25

Carrie A. Goss Haskell, San Francisco, Chicago Homeopathic Medical College, 1878, aged 77, died, April 7

Willis Grant Hatch @ Santa Cruz, Calif. Rush Medical College, Chicago 1897, aged 65, died, April 16

Harry Ford Scudder, Los Angeles Eclectic Medical Institute, Cincinnati, 1893, aged 63, died, April 9

George W. Simcoe, Fulton, Mo., Missouri Medical College St. Louis, 1881, aged 86, died April 22

Bureau of Investigation

ULTRASOL

Another Fantastic Cosmetic

An alleged hair grower "Ultrasol" is put out by a concern known as the Post Institute, New York City. It is said to contain "soothing oil, lemon juice, eggs, pituitary gland extract, sulphur." Elsewhere Ultrasol is described as a compound involving the presence of vitellin, nuclein, cerebrin, lecithin and cholesterol.

In its advertising the company has claimed that men and women after using Ultrasol, have reported enthusiastically that "fuzz at the temples grows to long, mature hair," that "abnormal hair falling stops," that "Ultrasol keeps the hair brilliant" and that "the scalp feels clean, fresh, free from dandruff." These statements are featured, and then follows the statement that "we do not claim that Ultrasol does any of these wonders."

In June, 1929, the Division of Legal Medicine of the Department of Health of the City of New York wrote to the Bureau of Investigation and stated that "the Post Institute is operating a quack game" and that the Department was anxious to get any information about one "Dr. John Post" who was alleged to have formerly practiced as a dermatologist in New York City and to have died in 1916. A most careful search of the files of the American Medical Association was made. From 1886 until 1916 there was no record of a man by the name of John Post who was a graduate of any reputable medical school who practiced in New York City as a dermatologist.

In June, 1933, the Federal Trade Commission wrote to the Bureau of Investigation with reference to an "alleged Dr. John Post" of 30 Irving Place, New York City, who had been described in an advertisement as a "Dermatologist to Royalty." The Commission stated that its efforts to elicit information on the alleged Dr. John Post had not been successful. The Commission stated further that it had been told that the Post person was an Englishman with a foreign degree and that he had conducted a sanitarium on Cape Cod and had died in 1918 or 1919. The Commission was told of the investigation made at the request of the New York Health Department in 1929 that had been unsuccessful, the Bureau also made another investigation at the time of the Commission's request. This was equally unsuccessful. Furthermore, the Commission was told that if John Post had conducted a reputable sanitarium on Cape Cod any time within the past quarter of a century, the American Medical Association would no doubt have had some record of the fact, it had no such record.

In 1934 the National Better Business Bureau wrote to the Bureau of Investigation regarding the Post Institute and its nostrum Ultrasol. The Better Business Bureau reported that the alleged ingredient of Ultrasol on which the Post concern placed most emphasis was pituitary gland extract, and the Bureau asked whether there was any evidence to indicate that rubbing pituitary gland extract on a bald head would raise hair. The Bureau of Investigation replied that the claim was about as fantastic a piece of hokum as had been seen for a long time. As a result of the Better Business Bureau's report on the Post Institute, a letter was written by one Louis J. Stern of the Institute, stating that the "value of the pituitary extract [in Ultrasol] does not depend upon its being absorbed through the scalp but rather in penetrating along the hair shafts to the hair glands." Mr. Stern further expressed the opinion that in "view of the fact that some extracts of the pituitary are capable of causing powerful uterine contractions in a dilution of one in one hundred billion, it is quite reasonable to suppose that when a powerful chemical such as this is applied locally, it would also have some value."

There seems to be no limit to the fantastic lengths to which certain exploiters of cosmetic preparations will go in selling their nostrums. They know, or course, that there is no national law that puts any penalty on the most preposterously misleading or even fraudulent claims. So far as the federal government is concerned, the sale of cosmetics today is as free from regulation as the patent medicine business was prior to 1907.

TREATMENT OF SCURVY WITH CRYSTALLINE VITAMIN C

To the Editor —Dr Irving Sherwood Wright of New York has called my attention to a report of his (Treatment of Adult Scurvy and Crystalline Vitamin C [Ascorbic Acid], *Proc Soc Exper Biol & Med* 32 475 [Dec] 1934), in which capillary fragility was reported as one of the signs of scurvy which responds to injections of cevitamic acid

Dr Russell and I would have quoted this earlier observation in our recent paper (The Effect of Cevitamic Acid Injections on Capillary Resistance, *THE JOURNAL*, May 11, p 1701) if we had been acquainted with it. It appears to be the first published report of the effect of cevitamic acid on capillary fragility. A complete report by Dr Wright will soon appear in the *Archives of Internal Medicine*

MENINGOCOCCUS TOXIN

To the Editor —The article entitled "Active Immunization with Meningococcus Toxin" by Ferry and Steele, published in *THE JOURNAL*, March 23, has provoked requests for this toxin to be used for active immunization against meningococcal meningitis. It was not the intention of the authors to convey the impression that this toxin is available for distribution or that proof of active protection against the disease had been established. In fact, in the body of the paper the latter phase of the problem is covered in the statement 'While the results of these tests indicate certain facts in regard to the stimulation of active immunity in man against meningococcus toxin they do not necessarily signify that an immunity against the organism can be produced at the same time'

SO-CALLED NEW DISEASES

To the Editor —Besides infantile paralysis and encephalitis spoken of by Hans Zinsser (*THE JOURNAL*, May 11, p 1700), many other diseases with marked characteristics have emerged within the last century, and even within the last few years. This seems strange, in view of the fact that it is often stated that physicians of the past possessed a very keen sense of observation and their 'horse sense' was by far superior to modern clinical and laboratory methods

In this connection it is of interest to quote a statement by the French clinician Edouard Rist

"It is strange," writes Rist (*La tuberculose*, Paris, Librairie Arman Colin, 1927), "that certain affections, the symptoms and course of which appear to us sufficiently characteristic as to be distinguished by simple clinical observation without the assistance of special technical methods, failed to be identified by our predecessors for many centuries. Measles and scarlet fever, for example, were first described in the eighteenth century and for a long period afterward were confounded with other diseases. Diphtheria, typhoid fever and pneumonia were identified at the beginning of the nineteenth century"

In truth," continues Rist, "the most reputable physicians of the past were poor observers. Nourished by dogmas and not by facts, enslaved by a scholastic mentality—resentful of criticism, they lacked the open minded attitude indispensable to the disinterested study of natural phenomena. They shared this deplorable state with scientists' in other branches"

One should not forget," goes on Rist, "that the scientific approach was initiated in the sixteenth century by a few

extraordinary personalities as Leonardo and Vesalius. To the end of the seventeenth century this was looked upon as a heresy, and only toward the end of the eighteenth century it, finally, won the respect and the encouragement of a very limited elite. Its triumph, which has upset the manner of thinking and the mode of living and which has changed the face of our planet, occurred only during the nineteenth century"

With all due respect to the triumph that modern medicine has attained, one must admit humbly that many diseases still escape observation in spite of the "open minded" attitude and technical perfection. Our successors, too, will probably discover 'new diseases' with "striking characteristics." They probably will speak of us in harsh tones such as Rist employs in speaking of our predecessors

NARCOTIC ADDICTION

To the Editor —I have a patient who has been using morphine since 1898 and has cost his brother who is quite well to do several thousand dollars. This patient has been in numerous sanatoriums and several years ago I was called to a local hotel to see him (I had never seen him before) and he told me his statement being confirmed by relatives, that he had just been released from a well known institution and had been pronounced cured. He was vomiting most severely and was beginning to enter into coma for several days it required considerable care on my part and with nursing he finally came out of it but only after I had administered in the presence of other physicians 3 grain (0.2 Gm.) doses of morphine sulphate. After I had obtained the man's history two other physicians and myself decided that he was a chronic addict and that morphine was essential for him to live. Time after time I have tried to reduce his dosage but finally gave it up as a bad idea and the other doctors decided likewise. It was agreed that he would come under article 85 exception 2 of the Harrison act wherein it was all right to give a chronic addict sufficient narcotics to maintain health. The patient has seemed willing to work with me and his brother gives him an ample allowance but his tolerance has reached the point at which I am at sea and want some advice. I have seen the man take 25 grains (1.6 Gm.) of morphine sulphate subcutaneously and apparently suffer no ill effects and at present I am giving him 3 drachms (11.6 Gm.) each week. Unless I do, he swells he is extremely toxic, for he does not eliminate respiration almost ceases and vomiting always occurs. A large dose of morphine relieves this. When I was in college in 1913 our teacher was a Dr. Schultz who was formerly (for twelve years) with the standardization of drugs department in the U S Health Service at Washington D C., and he told us that 3 grains was the maximum dosage of morphine. Can you enlighten me on this patient? He is 69 years old and does not drink alcohol to excess. Please publish for I would like to know how much morphine can be taken without the addict dying

M D West Virginia

ANSWER.—Drug addiction creates no physical disease necessitating its own continuance or renewal after the habit is broken. When the correspondent saw the patient for the first time he was suffering from abstinence symptoms. The continued narcosis locks up the secretions and excretions of the body, and catabolic products and intestinal fermentation produce a mixed toxemia. When an attempt is made to stop the use of the drug without proper treatment, pathognomonic withdrawal or abstinence symptoms appear, which are promptly relieved by a dose of morphine. These are the result of the release of cells from a long maintained functional depression or inhibition, taking the form of exaggerated activity of the different organs.

These symptoms last and increase from forty eight to seventy-two hours and then diminish. They vary and are not so severe as ordinarily supposed. There is no danger of death when the addict is in fair condition. The asthenic symptoms that follow the detoxication are due to the nervous exhaustion following the long period of continuous narcotization of the nerve cells and last about six weeks.

Either the patient had not been taken completely off the morphine or seventy-two hours had not elapsed since his last dose of morphine when he was released from the pay institution. There is also the possibility that if several days had elapsed since his discharge he had started using morphine again and that his supply had been interrupted.

That the number of deaths due to narcotics is not great is shown by the records of the Cook County coroner's office.

From 1916 to 1924 an average of six deaths from narcotics a year has occurred in Chicago and Cook County, and this figure includes victims who were not habitual users of drugs. A habitué develops a tolerance to large doses of morphine and it is questionable whether a fatal result could be produced in the patient by a drachm (4 Gm.) or more. While many addicts use more than 10 grains (0.65 Gm.) daily there is no real physical need, because if the addict is where his supply can be controlled from 8 to 10 grains (0.5 to 0.65 Gm.) of morphine will prevent any abstinence symptoms, but he does not get the pleasure or "kick" effect. When an addict says that he takes his drug only to feel normal, his ideas of normal are normal plus. This pleasure effect of narcotics varies in different persons from a feeling of comfort and relief to a wild, delirious "jag", so the amount used is usually limited by his available supply. A true comparison can be drawn in alcoholism, an alcoholic addict who is taking considerable daily amounts begins to suffer when his alcohol is stopped or attempts are made to reduce his regular dose, and in the morning he must have a drink or several drinks before he can carry on, if he does not get it he is a nervous wreck. Few morphine addicts use alcohol in excess. The solution of the drug evil does not rest on the administration of any specific treatment but rather on the removal, where possible, of the underlying causes for which the drug addiction is merely an expression. These causes vary in individual cases, it is not a mass problem. In the normal or nearly normal narcotic user who has acquired the habit through physical disease or discomfort which no longer exists or can be eradicated, if the patient is sincere and willing to stand, as most of us do, the mental and physical stress that is part of life's conflicts without resorting to narcotics, a permanent cure can be expected. For some patients good health plus normal life do not replace the sensations that narcosis means, and the possessors of these morbid types of personality will use narcotics as long as they live and narcotics are available. The patient in question belongs to this type and the probability of a permanent cure under existing conditions is slight unless he can be put away for a year or longer where the drug is unobtainable. Most relapses are not due to pain or ill health but to a desire for narcotic relief, which may mean anything from simple ease and forgetfulness to wild exhilaration.

EFFORT SYNDROME

To the Editor—Will you please discuss for me the following symptom complex and suggest treatment. A woman aged 30 married without children complains of repeated attacks of anginal pain localized in the fourth interspace just inside the apex a sense of precordial distress with pounding heart beat more or less all the time some nervousness and insomnia induced by consciousness of the heart beat. She says that she has always had a rapid heart rate. There is no history of any illness of importance. Over a period of several months the pulse rate has varied from 100 to 170 being usually about 150. The heart is not enlarged the apex beat is very forceful at times suggesting a thrill. At various times there has been a suggestion of a presystolic rumble although this has not been heard for several months. The radial pulse is full and regular. Roentgen examination of the heart and gastro-intestinal tract are negative. The basal metabolism is normal. The general physical examination gives negative results. The blood pressure averages about 130 systolic 84 diastolic. Gastric analysis gives normal results. Various medicines have been used in the treatment in addition to rest. The most benefit seems to have been derived from quinine sulphate in full doses and iodine although nothing has brought the pulse rate down nor have the precordial symptoms been entirely relieved. The patient is decidedly nervous, but she does not seem to be apprehensive about her condition and I think that her symptoms are decidedly real rather than imaginary. I shall appreciate any suggestions about this case. Please omit name and address.

M D Alabama

ANSWER—The symptoms and observations in this case of a normal sized heart by roentgen examination, normal blood pressure, a full regular pulse, and a normal basal metabolic rate suggest the diagnosis of effort syndrome as the cause of the symptom complex. The etiology of the disease is not known, but it occurs most commonly in females following excessive physical or mental strain. It occurred commonly in soldiers during the war as a result of the excessive effort while in civilian life the same men leading less strenuous lives would not be subject to the disease. The symptoms and observations are as indicated in the question. The treatment is often difficult and consists of reassuring the patient, trying to eliminate the causes for worry and mental distress and graduated exercises. This may involve sending the patient to new surroundings or a sanatorium where the difficulties may more easily be adjusted. The remote possibility of an adhesive tuberculous pericarditis with a normal sized heart must be considered as a cause for the symptoms. The cardiac symptoms are chiefly a result of the mechanical interference with the normal activity of the heart.

CARDIOVASCULAR SYPHILIS

To the Editor—Last October I was called to see a man, aged 30, complaining of precordial pain and a sense of oppression over the precordia. Close questioning gave a positive syphilitic history fifteen years before with treatment for one year. The treatment consisted of injections in the vein and the patient was pronounced cured. He also stated that he had three similar attacks within the past five years. Suspecting a possible syphilitic aortitis I had his chest roentgenographed, and the report was that a widening of the ascending portion and the arch of the aorta was present suggestive of aortitis. However, a competent clinician from his examination and his own observation of the roentgenogram expressed some doubt as to the diagnosis. The only clinical finding was a hyperactive knee jerk reflex in both legs. The Wassermann reaction was 2 plus. I started the patient on intramuscular injections of bismuth araphenamine sulphamate. Following the second injection an itchy maculopapular rash developed on the trunk and both arms. Discussion with syphilologists and the manufacturer placed the cause for this rash on the arsenic in the preparation. Hence I switched over to biweekly injections of 50 mg of a basic bismuth salt of camphocarboxylic acid. The rash disappeared. Up to the present time the patient has received twenty four injections. His Wassermann reaction after twelve injections amounted to a trace. A Kolmer reaction after twenty four injections was 2 plus. A spinal tap done after the first twelve injections showed the spinal fluid negative. Potassium iodide has been given with the foregoing medication. Up to now the patient has been feeling fine. Bimonthly urinalyses are negative. Please advise me as to further treatment also what will be the significance of a persistent Kolmer reaction? If printed in Queries and Minor Notes please omit name.

M D, New York

ANSWER—The probability is that this patient has cardiovascular syphilis. Precordial pain, substernal oppression and a widening of the ascending portion and arch of the aorta in the roentgenogram are almost pathognomonic of syphilitic aortitis. As the patient appears to have an intolerance to arsenical preparations, it would be best to continue medication with milder remedies. Iodides should be continued intermittently along with mercurial inunctions or mercury by mouth (mercury with chalk or yellow mercurous iodide pills). This can be alternated with a course of from eight to ten weekly injections of bismuth salicylate. Authorities differ as to the necessity or advisability of administering araphenamine preparations in cardiovascular syphilis.

The Kolmer modification of the Wassermann test is slightly more sensitive than the original Wassermann. The significance of a persistent Kolmer is about the same as that of a persistent positive Kahn test. Frequently the Wassermann reaction will become negative under treatment and the Kahn or Kolmer reaction may remain weakly positive.

USE OF DINITROPHENOL IN OBESITY DUE TO HYPOTHYROIDISM

To the Editor—My sister in law a registered nurse aged 37 height 5 feet 2 inches (157.5 cm.) weight 150 pounds (68 Kg.) during her second year of training in 1927 developed a toxic goiter and was treated in Dublin, Ireland. She was confined in bed fourteen months and was ambulatory six months before resuming training. Her pulse rate was 172 and she was given one hour of roentgen therapy to the front of the neck and one hour to the back of the neck in August 1927 and again two hours in the same manner in March 1928. She improved and finished her training. However hypothyroid symptoms now are pronounced she carries excess weight and her pulse rate is consistently 64. The tonsils were incompletely removed in 1918 and she has suffered severe headaches with chronic arthritis for the past ten years. The menstrual periods are regular of normal duration and without dysmenorrhea. She arrived in New York last September and while visiting there became worse and submitted to a physical survey. She had infected tonsil stubs and a streptococcal infection of both antrums ethmoids and sphenoids. The basal metabolic rate is -32. Nov 15 1934 the tonsil stubs were removed both antrums were drained through intranasal openings the ethmoids and sphenoids were cleaned up and a submucous resection was done. A copious pus drainage occurs as yet on each nasal douching but the arthritic pain in both shoulders and both knees and the headaches are diminishing. She has been taking 3 grains (0.2 Gm.) of Armour's thyroid daily for the last four weeks and thrives on it. She is gaining weight when she needs to reduce. In view of her history would dinitrophenol be too risky? What would you suggest to reduce her weight with this hypothyroidism present? If published, please omit name and town.

M D Ohio

ANSWER—The gain in weight following recovery from toxic goiter is not necessarily, or even usually, a manifestation of myxedema. It occurs frequently after thyroidectomy or roentgen treatment at a time when the basal metabolism is normal or even high and no definite signs of hypothyroidism (dryness or myxedema of the skin, physical and mental sluggishness, menstrual disturbances, low blood pressure, anemia, loss of hair, constipation) are noticeable. On the other hand, patients with typical postoperative myxedema with low metabolic rates may not gain much weight beside that due to water retention.

Weight gained immediately following recovery from thyrotoxicosis is chiefly that which was lost during the period of development of the toxic goiter. The gain is occasionally

greater than the previous loss, probably because the sudden shift from the negative to the positive energy balance upsets to some extent the previous level of body fat content regulation. The marked tendency to gain weight in the case described, seven years after recovery from thyrotoxicosis, might have spontaneously appeared at this period of life of the patient, regardless of the previous history, as it does in many cases of uncomplicated obesity.

Accordingly, the dietetic treatment of the obesity must receive as much attention in this case as in any other case. In addition the administration of thyroid substance is indicated in this case to combat water retention and relieve other symptoms of myxedema. The amount given may not be sufficient and should be raised to the tolerance limit, judged by clinical signs and by repeated metabolism tests.

Alpha-dimetrophenol (1-2-4) is probably no more risky in this than in other cases. It may cause a loss of weight but does not relieve the direct symptoms of myxedema (Tainter, M. L., Stockton, A. B., and Cutting, W. C. Use of Dimetrophenol in Obesity and Related Conditions. *THE JOURNAL*, Nov. 4, 1933, p. 1472).

ENLARGEMENT OF CERVICAL LYMPH GLANDS

To the Editor—A three year old girl was brought to me because of enlarged cervical glands on the left side of several months duration, apparently not dating back to an acute infection of the upper respiratory tract. These glands are distinct, are the size of beans and are not adherent to the skin. There are no other glands the spleen is not palpable. The child is apparently in the best of health is gaining weight and is very active. The remainder of physical examination is essentially negative. The tonsils are enlarged but apparently not diseased. The child has had no serious diseases. She had whooping cough about a year ago. A Mantoux test was markedly positive. A roentgenogram of the chest did not reveal any pathologic changes. There is no history of tuberculosis in the family. What is the significance of the positive Mantoux test in this case? Would it be advisable to remove the tonsils? Please omit name.

M D, Minnesota

ANSWER—While tuberculosis is only one cause of enlargement of the cervical lymph nodes, it must be considered, since the tuberculin test is positive. On the other hand, a positive test does not necessarily mean that the tuberculous disease is in the lymph nodes. The test indicates merely that tuberculosis is present somewhere in the child's body. The fact that the x-ray film does not reveal any evidence of pathologic changes in the lungs is not significant. In such cases, x-ray films are helpful only when they reveal definite evidence of disease. A negative film of the chest, like a negative laboratory examination of the sputum, by no means rules out disease. Tuberculous foci of first infection often exist in the lungs of such size that they do not cast shadows on the x-ray film that one is able to visualize, therefore the negative film of the chest is not good evidence that the tuberculous lesions are not in the lungs. There is no way to determine with certainty whether or not the cervical lymph nodes are tuberculous except through biopsy and they are so small that this would hardly seem justified. If the nodes are the seat of the tuberculous foci, x-ray films through the cervical region may in time show evidence of calcium deposits in them. While this is good evidence of tuberculosis, it cannot be compared with biopsy from the standpoint of accuracy in diagnosis.

The fact that the child is in the best of health is gaining weight and is very active is quite in keeping with the first infection type of tuberculosis. Indeed, there usually are no outward manifestations of the existence of this disease in children of any age. Drolet has called attention to the fact that only 103 per cent of children who develop the first infection type of tuberculosis up to the age of 15 years die of tuberculosis.

The same condition that resulted in hypertrophy of the tonsils may be responsible for the enlargement of the cervical lymph nodes. There is controversy regarding the removal of tonsils in children but the general opinion is that unless they are definitely infected and are harbingers of pathogenic microorganisms, such as tubercle bacilli, or are sufficiently large to obstruct the air passages it is better not to remove them.

Even if the lymph nodes should prove to contain tuberculous lesions in all probability it is of the first infection type and no special treatment is indicated. In a child of 3 years with a positive tuberculin reaction, the source of the disease will probably be found in an unsuspected form in some of the close human associates. The best treatment consists of finding the source and breaking the contact with the child. Beyond that the ordinary care that any normal child should receive by way of diet and atmospheric conditions is all that is necessary. However as the period of puberty is approached periodic examinations including x-ray films of the chest should be made every year and preferably every six months, since it is during this period that the destructive type of tuberculosis begins to make its appearance with considerable frequency.

ORR TREATMENT OF FRACTURES AND OSTEOMYELITIS

To the Editor—Please describe the Wionett Orr treatment of infected fractures and osteomyelitis. Please omit name.

M D, New York.

ANSWER—Orr's method was developed as a reaction against practices which included timidity in operating, overboldness in operating, failure to drain adequately, inability to recognize acute bone abscess, and too many disturbances during the patient's attempt at healing.

The principles of the Orr treatment include (1) good surgical operation providing adequate drainage, (2) wide-open packing of the wound with petrolatum gauze, (3) immobilization of the extremity, and (4) the minimum number of dressings.

Orr's chief contributions to this subject are (1) the reduction in the number of dressings, that is, the reduction in the number of times the wound is exposed to further contamination and the reduction of the pain and suffering that are caused by repeated dressings, (2) rest of the wound, (3) avoidance of painful dressings, and (4) the saving of the bacteriophage.

Orr advises (1) immediate adequate drainage at whatever stage the osteomyelitis is encountered, (2) the maintenance at rest of inflamed parts by the application of a plaster-of-paris cast, aided if necessary by ice tongs or other methods of skeletal fixation, (3) wide-open drainage by means of a sterile petrolatum pack, (4) primary asepsis or antiseptics, avoiding the use of irritating antiseptics in the wound, (5) postoperative care, emphasizing rest without antiseptic dressings, which usually increase and complicate infection, (6) maintenance of all injured parts, bones and soft parts, in their correct anatomic position during the entire period of healing.

In a discussion of the treatment of compound fractures, Orr states that a certain dexterity in the use of moleskin traction, plaster-of-paris and skeletal traction devices, sometimes included in plaster-of-paris casts, is essential. He states that these appliances are not only comparatively simple and easy to use but also more effective than other splints and traction devices in ensuring more permanent length, correct position and immobilization. The first operation sees the wound cleaned and the bones immobilized in the correct position.

Orr states that, when a compound fracture occurs, the bones involved are not only broken but thrown forcibly out of their normal position. It is therefore of paramount importance that these bones be restored as nearly as possible to their correct position and that between the time of fracture and the time of restoration as little damage as possible be done to the tissues surrounding the fracture. To ensure this, it is best to splint the patient at the scene of the accident and to place the bones in the correct position at operation and immobilize them. It is highly important that this immobilization be maintained.

Wound treatment is secondary in that it is possible to provide an aseptic wound that will heal easily and satisfactorily while at the same time giving primary consideration to the fractured bones. He advises wide open drainage without the use of drainage tubes, usually without sutures.

The correspondent should refer to a book by Dr. H. Wionett Orr, called "Osteomyelitis and Compound Fractures," published by the C. V. Mosby Company, St. Louis, in 1929.

ATROPHY OF TESTIS AFTER INGUINAL HERNIOTOMY

To the Editor—Are there any statistics available that will show the percentage of atrophy of the testicle following inguinal herniotomy? A local doctor—not a member—is urging suit against one of our local surgeons because of atrophy of the right testicle following herniotomy. I do not know the type of repair used but told the doctor and attorney that in my opinion the fact that the testicle is atrophied following the operation does not prove poor surgery or mismanagement and made the statement that often orchitis followed hernial repair and that sometimes atrophy followed. They want to know in what percentage atrophy follows and I cannot even guess at the figure. Of course it is small but the fact that it has happened before may help prevent this case going further.

M D, Illinois

ANSWER—W. S. Halsted reported (Discussion on Hernia. *Tr. Am. S. A.* 13:343, 1895) three cases in which atrophy of the testicle occurred after his operation for hernia, in which some of the large veins were ligated to diminish the size of the cord. He stated that they had stopped ligating the veins of the cord as a routine part of his operation.

Cattell and Anderson, in a follow up of 150 patients operated on for hernia at the Lahey Clinic found (*New England J. Med.* 205:430 [Aug. 27, 1931]) that in ten, or 6.7 per cent, of cases examined there was evidence of atrophy of the testicle on the operated side. In none of these was there any atrophy noted previous to operation. They emphasized the importance of leaving an adequate opening for the passage of the cord without interference with its blood supply. In five of these cases

in which atrophy occurred, operation had been done by the Gallie technic. In the other cases apparently the Bassini technic was used.

In a report of 1,878 operations for hernia (*Tr Am S A* 48 306, 1930) Gibson and Felter reported the occurrence of epididymitis and orchitis twenty-one times, or 11 per cent, the cutting with repair of the vrs twice, the cutting of the cord followed by removal of the testicle once, hydrocele seventy-four times, spermatocele once and varicocele twenty-three times. They did not report the incidence of atrophy of the testicle, but it is well known that atrophy of the testicle frequently follows traumatic epididymo-orchitis. McCullagh reported (*M Clin North America* 17 969 [Jan] 1934) the occurrence of hypogonadism in two cases seen following hernia operations. In both cases the testicles were smaller than the average, but there was no record of the size before operation.

Claverley called attention (*Lancet* 1 277, 1917) to the occurrence of atrophy of the testicles on the same side with a hernia before operation and reported two cases which he thought were coincidental rather than due to a developmental condition. He emphasized the necessity of the patient signing a statement of this condition before operation as a safeguard to the surgeon in case of litigation.

DRESSING FOR LABORATORY TABLES

To the Editor—Some time ago if I am not mistaken there appeared in this department of *THE JOURNAL* a description of a method for finishing the tops of laboratory desks. Can you supply me with the formula?

D W CARTER JR MD Dallas, Texas

ANSWER.—As considerable time has elapsed since we published the formula for an ebonizing preparation to render laboratory tables resistant to staining or corroding chemical reagents we repeat it herewith.

Solution A	
Copper sulphate and potassium chlorate each	125 Gm
Water	1 000 Gm
Boil till salts are dissolved	
Solution B	
Aniline hydrochloride	150 Gm
Water	1 000 Gm
or	
Aniline	120 Gm
Hydrochloric acid	180 Gm
Water	1,000 Gm

Two coats of Solution A are applied while hot, the second as soon as the first has dried. Two coats of Solution B are applied and the wood is allowed to dry thoroughly. Next a coat of raw linseed oil is rubbed in by means of a cloth to give a polish. In the treatment with the oil, the deep black color is partially brought out, but this does not uniformly appear until the table has been thoroughly washed with hot soapsuds. The latter treatment removes superfluous chemicals. To keep the table in condition, it is said to be necessary only to wash off occasionally with soap and water and then to rub with oil. The amount is sufficient for 10 square yards of surface.

FRACTURE OF HIP IN WOMAN AGED FIFTY

To the Editor—What possibility of walking may be promised in a case of intracapsular fracture at the hip with nonunion? This fracture, in a woman in the fifties was immediately at the junction of the head and neck of the femur treated by a Steinmann pin and extension and internal rotation. No union occurred, and when absorption of the neck was noted to begin in ten weeks the patient was returned home as she did not wish open operation. There is now 3 inches shortening and 75 per cent normal active movement. Will she be able to bear weight and walk and when should she start weight bearing or what treatment is indicated? Please omit name.

MD New York

ANSWER.—A woman in the fifties with an ununited fracture of the neck of the femur and 3 inches of shortening should certainly have an operation performed if she is a reasonably good surgical risk. A Whitman reconstruction would enable her to be up and about much earlier than a bone graft or a Brackett operation but would result in slightly more shortening than the other methods.

If no operation is accepted, she can begin to bear weight at once, using crutches and gradually increasing the time and amount of weight bearing. The ultimate shortening will be 3½ or 4 inches, and the hip joint usually remains quite painful. The body weight is borne by the capsule and ligaments, like a sling and walking is difficult and unstable with a marked limp. A high soled shoe or a metal patten must be used to equalize the length of the legs.

The late result of a nonunion therefore is extremely unfavorable and every effort should be made to obtain the consent of the patient to an open operation.

POISONING FROM COMPOUND SOLUTION OF CRESOL FOLLOWING UTERINE INJECTION

To the Editor—I wish to secure some information regarding the toxic effect of cresylic acid, which is commonly used and sold under the trade name of Iysol particularly in connection with the absorption of this substance through the uterus when injected to produce an abortion. In this case the solution was injected through the uterus by catheter to produce an abortion. The patient was delirious and unconscious within half an hour and died two days later without regaining consciousness. The theory, however, for the death of this woman was that cresylic acid was absorbed directly into the blood stream in this way. As soon as the solution found its way into the cavity of the uterus the uterus would make an attempt to expel it in the way of contraction of the elastic fibers of the uterus then on the rebound part of the placental tissue would be detached from the uterine wall and the large veins through which the young fetus is being fed and nourished would suck in the solution and in that way it would get into the blood stream. This is a rather unusual occurrence and I would like full information regarding the possibility of this occurring. I am of the opinion that the girl died not from the condition as stated but from poisoning due to taking emmenagogues. At autopsy in this case the stomach of the patient was found to be perforated probably the result of autodigestion. Could you advise me how soon this would occur after death and in what percentage of autopsies autolysis of the stomach occurs within forty-eight hours of death.

LOUIS PANCARO, MD, Sudbury, Ont

ANSWER.—In view of the circumstances described in this case the possibility of poisoning from compound solution of cresol following intra-uterine injection cannot be denied. Witt- haus and Becker (*Medical Jurisprudence, Forensic Medicine and Toxicology*, ed 2, 4 1187, 1911) state that they have collected the reports of eleven poisonings by uterine irrigation with five deaths, in three cases the irrigation was made to produce abortion and in one case death occurred. No emmenagogues give rise to symptoms like those described.

The stomach may digest itself more or less under many different conditions. The digestion may start almost at once after death, especially in the posterior wall of the fundus and at the junction with the esophagus, because those parts ordinarily come in immediate contact with the gastric juice. Naturally, the state of secretory activity at the time of death is important. Self digestion is favored by warm weather. The entire thickness of the wall of the stomach may be digested and the process may even extend to neighboring organs. Just how quickly and how extensively digestion may occur cannot be stated in definite terms, because the factors involved are subject to great variation.

PORTAL CIRRHOSIS WITH ASCITES

To the Editor—1 How frequent are spontaneous remissions in decom- pensated portal cirrhosis without treatment? 2 Can the current high carbohydrate diet alone cause disappearance of the ascites? 3 Do you know of any instances in which the xanthine group of diuretics used alone notably theocalcin have caused the disappearance of the ascites?

BENJAMIN J MACCHIA, MD Jersey City, N J

ANSWER.—1 Spontaneous remissions do occur but far too infrequently to afford any basis for statistical data. Dense adhesions may be found resembling those of a Talma operation without any history indicating when the inflammatory processes occurred. Adhesions may follow repeated tapplings, resulting in a remission.

2 A high carbohydrate diet is of great advantage to such patients but there is no reason to suppose that it could possibly cause a remission of the ascites.

3 There are no reported instances available in which the xanthine group of diuretics used alone have caused the disappearance of the ascites. In a case of cardiac decompensation with what may be considered a cardiac cirrhosis of the liver, it is conceivable that one of these diuretics might effect some improvement, although it is very doubtful.

EFFECTS OF INSULIN ON SERUM

To the Editor—What are the effects, if any of insulin on the blood serum in vitro? I would appreciate any information you can give me on this subject. Please omit name.

MD New York

ANSWER.—There is no generally accepted action of insulin on blood serum in vitro.

Lundsgaard and Holbøll (*J Biol Chem* 62 453 [Dec.] 1924, 70 71 [Sept] 1926) reported that insulin and finely minced muscle tissue acting together change the optical rotation of dextrose without altering its reducing power, i e, the mixture converts dextrose into a new form.

Berry and Moquet (*Compt rend Soc de biol* 93 322 [July 10] 1925, abstr *THE JOURNAL*, Oct. 17, 1925, p 1259) found that the spontaneous disappearance of dextrose and phosphates from the blood in vitro was accelerated by the addition of insulin.

SUBACUTE BACTERIAL ENDOCARDITIS

To the Editor—Kindly let me know who was the first one who brought out the diagnosis of 'subacute bacterial endocarditis (septic)' caused by *Streptococcus viridans*. Were there ever reported any cases that were cured and if so what was the treatment? How many cases were cured, if any? Somebody has said that Dr Libman and Dr Baird from Mount Sinai Hospital New York were the first who discovered that disease. Dr Harlow Brooks it was said asserted that he cured six cases. Out here in Boston I spoke to several cardiologists and none know of any cures or have heard of any cures.

BERNARD ZUCKERMAN M D Dorchester Mass

ANSWER.—It is hard to give any one man the credit for bringing out the diagnosis of subacute endocarditis. Prolonged forms of endocarditis were described by Jaccoud as early as 1882 by Osler in 1885 and by numerous other authors in subsequent years. Schottmüller described it as endocarditis lenta in 1910 and the disease is occasionally referred to by his name. He deserves a great deal of credit for calling attention to the subacute form.

There have been several cures reported which have stood the test of time. It is possible that this number would be increased by earlier diagnosis in the milder forms. It is possible also that several very mild forms have recovered without being diagnosed.

There is no specific treatment available, and rest and time are still the chief factors. The correspondent is referred to *Studies on Bacterial Endocarditis* by William S Thayer, *Johns Hopkins Hospital Reports* 1926, where treatment was discussed on page 168 and to Dr Libman's report appearing in the *Transactions of the Association of American Physicians*, 1933, page 44.

It would be much better to go through these articles and others to which references will be found than to rely for information on such a short response as can be given here.

DIFFERENTIAL DIAGNOSIS OF MYASTHENIA GRAVIS

To the Editor—A man aged 33 5 feet 11 inches (180 cm) in height of large boned type 205 pounds (93 Kg) in weight complains of excessive fatigue. He is emotionally stable. The weight was 230 pounds (104 Kg) four months ago at which time he was definitely conscious of overweight and had the beginning of his fatigue. By diet and exercise the weight was gradually dropped to its present level. It seemed that after his weight began to drop below 220 pounds (100 Kg) his fatigue progressively increased. Now he complains of being tired at all times and at the end of the day (he is an office worker) he can barely keep on his feet and he looks it. The blood pressure is normal the basal metabolism is -5 per cent (checked twice by different individuals and records taken one month apart) and the blood sugar is 80. Everything else is normal and I have had my figures checked by two good internists. Thyroid was suggested for a try-out and I gave 2 grains (0.13 Gm) of a standard preparation three times daily for four weeks. This had no apparent effect on the fatigue but did increase perspiration and slightly accelerated the weight loss. The patient says he does not seem to have much choice that when his weight is way up he feels puffed up like a swelling toad and has a little shortness of breath and when his weight is where it is now he has fatigue that he cannot overcome. Suggestions will be greatly appreciated. Please omit name.

M D Virginia.

ANSWER.—The data given are far too meager on which to base a diagnosis. Muscle weakness and fatigability are due to many causes and the differential diagnosis of the various conditions is usually quite difficult. In this case myasthenia gravis as well as other conditions for example Addison's disease, should be considered. On the other hand the condition may be simple fatigability. A suggestive symposium on some of the various forms of myopathy and the results of treatment in the different groups with fatigability was recently presented by Moersch, Boothby, Wilder and their associates (*Proc Staff Meet Mayo Clin* 9 589 [Oct 3] 1934) which might furnish suggestions appropriate for this patient.

RETARDING GROWTH

To the Editor—Is there any known method of retarding the growth of the long bones? The patient is a girl of 10 in good health. Please omit name.

M D New York

ANSWER.—There is no adequate method for controlling the growth of the long bones in healthy persons. If an anterior pituitary tumor is present, its removal would stop excessive growth. High voltage intensive roentgen therapy might be administered to the pituitary, but so many functions reside in this organ that such procedures might prove harmful in other directions, especially in subsequent gonadal development. Watchful waiting is probably the wisest plan to follow for the present.

California February Examination

Dr Charles B Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held in Los Angeles, Feb 5-7, 1935. The examination covered 10 subjects and included 90 questions. An average of 75 per cent was required to pass. Sixty-four candidates were examined, 56 of whom passed and 8 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
University of Arkansas School of Medicine	(1932)	94.4	(1934) 86.1
College of Medical Evangelists	(1931)	87.9	(1934) 90.6

Book Notices

The Content of Motion Pictures [Combined with] Children's Attendance at Motion Pictures By Edgar Dale Research Associate Bureau of Educational Research Ohio State University. Cloth Price, \$2.50. Pp 234 81 New York Macmillan Company 1935

This volume contains two separate and distinct studies. The study of the content of motion pictures is a most intensive and meticulous one. The writers have gone to untold trouble to arrive at an objective evaluation of what actually is in motion pictures, not what the observer reads into them by virtue of preconceived notions and prejudices. The general themes of 1500 motion pictures have been studied and, in addition, 115 of the same pictures have been subjected to more intensive analysis, while forty have literally been put under the microscope. Not only general themes have been studied, but locales and settings, leading characters, clothing worn, circumstances of meeting and lovemaking, sex, marriage, and romantic love, crime, vulgarity, recreation, liquor and tobacco, and the goals sought by the leading characters. Besides this the content of newsreels has been studied. In the summary it appears, according to "a balance sheet for motion-picture content," that heavy emphasis has been placed on the life of the upper economic strata, on metropolitan localities, on problems of the unmarried and the young, on problems of love, sex and crime, on the motif of escape and entertainment, on interest appeal to young adults, on the professional and commercial world, present problems in a limited field, comedy foreign characters, diverse and passive reactions, individual and personal goals, crime technic, the romantic and unusual in friendship, "living happily ever after," physical beauty, physical action, and, in the newsreel, sports and trivial happenings. On the contrary, scant attention has been given to life of the middle and lower economic strata, small towns and rural areas, problems of the married, middle aged and old, problems of everyday life, social enlightenment, interest appeal to children and older adults, industry, agriculture, governmental problems representative foreigners, active and inexpensive recreations, social goals, causes and cures of crime, undramatic and enduring friendship, happy marriages, beauty of character, and, in the newsreels, world news of an intellectual and undramatic character, scientific observations, and pictures of real conditions in the different parts of the world.

The second study deals with children's attendance at moving pictures and gives attention to children's companions in the movies, frequency of attendance, time of attendance, and age composition of the motion picture audience. The conclusion, which could have been anticipated, is that children and youth the country over are frequent patrons of motion picture theaters that they contribute a larger percentage of the total audience than has been commonly believed, and that therefore the effect of motion pictures is universal and must be faced in a statesmanlike manner by exhibitors, producers, teachers and parents.

The book is an excellent contribution to the store of factual material on which advancement of the motion picture as an educational force must be based.

Glándulas endocrinas y prostitución Por Dres J J Bereterride y S Rosenblatt. Prólogo del Prof Dr Mariano R Caelex. Paper Pp 254. Buenos Aires Librería y Editorial El Ateneo [n.d.]

The authors have examined 110 prostitutes, apparently thoroughly and with great care, and they have attempted to correlate their observations with the present knowledge of endocrinology. It is difficult to understand why the authors chose to use biologic methods in the study of an economic disease. This alone is sufficient to raise serious doubt as to the fundamental value of the work. It appears further however that, of the few reliable methods available to evaluate the function of the endocrine glands, fewer still have been employed in this investigation. Many if not most of the correlations are purely theoretical, these in turn are based in large part on half-baked theory which the authors have uncritically culled from the vast literature of endocrinology. However, they have assembled a large amount of data, while the significance of the information as related to prostitution is not clear some of it may possibly be useful for reference.

Economic Problems of Medicine By A. C. Christlo Professor of Clinical Radiology Georgetown University Medical School. Cloth Price \$2 Pp 242 New York Macmillan Company 1935

Such a book, "written from the viewpoint of the private practitioner of medicine," fills a real need. It is based on the application of the principles of medical ethics to present economic conditions and surveys the economic side of medical education, private practice, the hospital, medical organization and the community. There are chapters on workmen's compensation, health insurance, industrial medicine, medical society experiments, and a final chapter discussing the "Essential Elements in a Comprehensive Plan for Medical Care." It assumes that "if the physician is to fulfil his whole duty to his community he must maintain a position of leadership in everything that pertains to the people's health."

The chapter on "The Physician and the Medical Organization" summarizes the great contribution made to society and to the profession by the American Medical Association and constituent societies. County medical societies are constantly assuming more effective and extensive leadership in all matters concerned with the health of the community. It is not fair to blame physicians for defects in present society. "The causes of this condition are interwoven with the social and economic structure of present-day civilization, and the cure for it must be sought in more equitable distribution of the fruits of industry." The origins of health insurance for example, are due to the fact that "the conditions of modern industry imposed a wage upon laborers so close to a bare subsistence plane that it was only through compulsion that health insurance could be maintained."

The chapter on "New Methods of Medical Care Under Trial or Recommended by Medical Organizations" describes the plans conducted in Alameda, San Diego, Detroit, Washington, D. C., and other places. There is an impartial consideration of the merits and demerits of health insurance and a final summary of the "Essential Elements in a Comprehensive Plan for Medical Care."

It is a work that deserves study by all those who are interested in medical economics. If some criticism must be made to make an impartial review, objection might be raised that too great reliance is placed on the reports of the Committee on the Costs of Medical Care.

Collected Papers of St. Mark's Hospital London Including a History of the Hospital Centenary Volume 1835-1935 Compiled by the Medical Committee April 1935. Boards Price 30s Pp 440, with 96 illustrations. London H. K. Lewis & Co. Ltd. 1935

In London in 1835 Dr. Frederick Salmon founded St. Mark's Hospital for the treatment and study of the "diseases of the rectum in all their baneful varieties." The hospital has grown and flourished and now in 1935 the medical committee has published a centenary volume in honor of the completed century of usefulness. This volume contains a series of collected papers written by Dr. Salmon and the staff that has succeeded him. A study of the early papers is interesting indeed. The modern surgeon will find much that is amusing and much that is stimulating. In a paper on stricture Salmon attributes this condition in one of his patients who had just returned from a polar expedition to sitting on the ice, and yet in the same paper there is a good differential diagnosis between the benign and malignant varieties. The antipathy to chloroform is noted in a paper in 1857 because of increased bleeding resulting from relaxation of the sphincter, although it is evident that the anesthetic was used at that time by most surgeons. An article on the injection treatment for hemorrhoids, written in 1888 might have been published by one of the advocates of this form of treatment today, the evils of this injection of strong solutions are denounced in an article published in 1924. The shaping of present ideas concerning the treatment of cancer of the rectum and lower portion of the bowel is seen in the series of articles on this subject from the time the hospital was founded up to the final stage of present-day methods as described in Gabriel's excellent article on one stage perineo-abdominal excision of the rectum in 1934. The book is well printed on glazed paper and has an exceedingly attractive binding simulating the style in vogue a hundred years ago. A short history of the hospital completes the record. The collection will appeal especially to

all proctologists or physicians interested in proctology, because in it to a certain extent they will be able to relive the development of their specialty. Physicians interested in medical history will enjoy owning and perusing its contents.

The Romance of Exploration and Emergency First Aid from Stanley to Byrd Cloth. Pp 160 with illustrations. New York and London Burroughs Wellcome & Co. [n. d.]

This book is frankly an advertising brochure but it is at the same time a charming souvenir and an interesting series of historical highlights on exploration and emergency first aid. When a commercial product has been to all sorts of remote and inaccessible regions, including both poles and the depths of the Dark Continent, it ceases to be a mere commodity and becomes a historical relic. Burroughs Wellcome & Co. has offered first aid and medical equipment to all the important explorers since Stanley. While deprecating the unwillingness of this company to cooperate with efforts of the Council on Pharmacy and Chemistry of the American Medical Association, one can still recognize its contributions, both directly and indirectly through the Wellcome Institute, toward the development of fine pharmaceutical products and compact first aid equipment that will stand the vicissitudes of extreme climates and varied conditions of transportation.

Arzneikunde und Arzneiverordnung Ein Lehrbuch Von Prof. Dr. Otto Reisser und Dr. Gert Taubmann. Paper Price 12 marks Pp 430 Berlin & Vienna Urban & Schwarzenberg 1935

As the authors state in the preface, the purpose of their work is to supplement but not to replace lectures on pharmacology, they did not intend to cover the subject thoroughly, and the reader seeking further information is referred to larger textbooks. Since pharmacology developed into an independent branch of medicobiologic science, it became necessary not only to describe the mode of action of drugs but to discuss the causes of such action. Conforming with this requirement, the authors divided each chapter into two parts, theoretical and practical. Description of the therapeutic application of drugs is preceded by an evolution of its scientific basis, this arrangement of the text reflects the fact that pharmacology stands on the borderline between the theory and the practice of medicine. The authors are familiar with the aversion of the majority of medical students to chemistry, however, the knowledge of composition of drugs is essential and therefore attached charts offer an easy survey of chemical formulas. Certain drugs well known in the United States, such as mercurochrome, acriflavine and mucin, are not mentioned. A statement that ethylene is not a popular anesthetic certainly does not apply to this country. Vermicides have been described in an inadequate manner. Bibliographic references have been omitted because, as stated the work is not to serve as a textbook. The biologic approach to the subject is highly instructive, the style fluent. One who looks for instruction in prescription writing will be disappointed, but the book offers a well balanced presentation of everything that is modern in pharmacology and deepens the understanding of the physiologic aspect of this science.

Principles of Genetics and Eugenics A Study of Heredity and Variation in Plants Animals and Man By Nathan Fasten Ph.D. Professor and head of Department of Zoology Oregon State College. Cloth. Price \$2.80 Pp 407 with 120 illustrations. Boston & London Ginn & Company 1935

For the beginner in the study of genetics and eugenics this is an exceptionally clear, well organized and well written book. From its opening chapter on the scope and need of genetics through various theoretical considerations to the chapters on problems of genetics and eugenics and human betterment, it deals with difficult and complicated questions in a clear and sane manner. It has an ample bibliography containing 213 references, a glossary of twenty-six pages, and an index of sixteen closely printed pages, which add much to the practical value of the volume, as do many helpful diagrams and a few photographs. For the teacher of biology, for the reference library, for the high school, for the junior college and for the general community library, this is an excellent book of elementary principles. While the handling of the subject is sufficiently simple for the beginner, it is not so elementary that the more advanced student will not find the book useful.

Le nodule de la corde vocale Par Jean Tarneaud oto rhino laryng. ologiste de l'Hôpital Bélian et du Conservatoire national de musique de Paris. Préface de M le Professeur Sebileau. Paper Price 30 francs Pp. 139 with 24 illustrations. Paris: Norbert Maloine, 1935

This is a rather large book, relatively speaking, on small objects, the vocal nodes or singers' nodes, as they are called. Since even the tiniest of nodes are sufficient, in many instances, to ruin the fine quality of the voice and thus bring disaster to the career of the artist, the importance of the subject will justify the detailed discussion of it by Jean Tarneaud. The subject is systematically treated. There is a preface by Professor Sebileau, followed by a chapter on the etiology of the nodule. The author discusses the various theories and feels that a general hypotonicity of the laryngeal muscles always rests at the basis of the formation of the nodes. There follow the chapters on the pathology and the clinical forms, together with symptomatology and diagnosis of singers' nodes. Both the medical and the surgical treatment of the various forms of nodes is discussed, followed by a chapter on the treatment of the voice. A rather complete bibliography concludes the volume. This work is based on many years of clinical experience and investigation, and its perusal will bring much information to the laryngologist interested in this subject. The facts are presented with a clearness that is usually characteristic of French writers, and the illustrations are helpful.

Martin's Principles and Practice of Physical Diagnosis Edited by Robert F. Loeb M.D., Associate Professor of Medicine, College of Physicians and Surgeons, Columbia University. From an authorized translation by George J. Farber M.D. Cloth. Price \$2. Pp. 213 with 30 illustrations. Philadelphia & London: J. B. Lippincott Company, 1935.

Dr. Martin dedicates this book "to teaching the essentials of seeing, hearing, and feeling in their relation to the body in health and disease. The training of these three faculties represents the foundation without which the development of the student of medicine is impossible." Most works on physical diagnosis are so voluminous that they can be used only for reference. This little volume can be carried in the pocket to be used as a guide and ready reference by the student. Chapters are devoted to general examination, to examinations of the respiratory and circulatory system, and to an examination of the abdominal organs. Outlines for history taking and recording of physical examination are appended. The work is concise and thorough and can be highly recommended as a handbook for students.

Women on Their Own By Olga Knopf M.D. Edited by Alan Porter. Cloth. Price \$2.75. Pp. 306. Boston: Little Brown & Company, 1935.

In this book the author discusses the position of woman in America today and all her relationships with men and other women in work, at home, in pleasure and, indeed, in all the aspects of woman's life. She takes up the question of friendships between men and women and between women and other women, paying a considerable amount of attention to the choice of occupation and to the question of marriage as opposed to a career. The book is written with rare understanding and calls attention in case histories to some of the individual problems that have come to her attention. She sees nothing but a broad outlook for woman in the future, with increasing opportunities. Incidentally, Dr. Knopf is a pupil of Alfred Adler and represents the school of individual psychology.

Die Hormonforschung und ihre Methoden Von Max Reiss. Dr. med. Dr. rer. nat. Privatdozent für pathologische Physiologie an der Deutschen Universität in Prag. Paper Price, 15 marks. Pp. 415 with 26 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1934.

This book is apparently intended to be a brief but comprehensive survey of present knowledge of endocrinology, including descriptions of technical methods and an extensive bibliography. It is designed primarily for the use of investigators. Adequate discussion of so detailed a work is impossible in a limited space; this would require a book of no mean proportions in itself. It appears that the author, who is to be commended at least for zeal and industry, has not attained his primary aim. Perusal of any section chosen at random reveals that much essential information has been omitted and that a great deal of non-essential, unconfirmed, unconfirmable and definitely erroneous

material has been included. Little effort has been made to distinguish between demonstrated fact and the overwhelming number of fanciful excursions into endocrinology with which the physiologic literature is deluged; this volume will serve at least as much to perpetuate error as it does to present fact. The bibliography (which is extensive but not by any means complete) and the section on technical methods may be of use to investigators; a large part of this book otherwise will be chiefly of historical interest. The format is poor for an encyclopedic work of this kind, so that in many cases a desired subject (perhaps fortunately) is difficult to find. The author has essayed a task that could adequately be accomplished only through the cooperation of many experts; endocrinology is too vast a subject and it is moving at too fast a pace to be successfully reviewed in its entirety by one man.

Leitfaden der Pathologie und Therapie der Kampfgaskrankungen Von Dr. med. Otto Muntsch, Oberstabsarzt im Reichsheere. Third edition. Boards. Price 11 marks. Pp. 132 with 43 illustrations. Leipzig: Georg Thieme, 1935.

The fact that this monograph is in its third edition since 1931 is sufficient evidence of its popularity. The author has attempted to portray particularly the pathologic effects of the poisonous gases used in warfare. Twenty-two beautiful colored plates illustrate the clinical and histopathologic effects on the various organs that may be affected. The seven chapters deal with the history and development of chemical warfare, the general toxicology and chemistry of the most common war gases, the specific pathology and therapy of the effects of war gases, and the late effects and the methods and principles used in combating and treating war gas injury. There is an excellent bibliography from both German and foreign literature and a convenient index. This booklet will be of great service to all pathologists who may deal now or in the future with war gas injuries.

Capitalism Carries On By Walter B. Pitkin. Cloth. Price \$1.75. Pp. 282. New York & London: Whitteley House, McGraw-Hill Book Company, Inc., 1935.

Mr. Pitkin is an eminent journalist who has written journalistically about many topics and with great success. He here offers his views as to our future in relationship to the capitalistic system. His book is full of truisms, and he brings himself to the view that the capitalistic system must carry on in the United States, but that, of course, it must modify itself to changing conditions. He looks on the middle class as the hope of humanity, at present being ground to dust through the desperate rich and desperate poor.

Wissenschaftliche Forschungsergebnisse. Naturwissenschaftliche Reihe. Herausgegeben von Dr. Raphael Ed. Liesegang. Band XIX. Hormone und innere Sekretion. Von Dr. Fritz Laquer, Professor an der Universität Frankfurt. Second edition. Paper. Price 18 marks. Pp. 368. Dresden & Leipzig: Theodor Steinkopff, 1934.

In preparing the second edition of this well known work (the first appeared in 1928), the author has added some 6,000 references to the bibliography. The format is excellent and the bibliography extensive (but not complete) and well arranged, the book may therefore be useful for reference. However, there are a great many serious omissions from the text (for instance, the fundamental work of Hanson on the parathyroid is not even mentioned) and many of the discussions are uncritical and inaccurate. Much of the work is simply a compilation from the literature. Thus this volume, like so many others on the difficult subject of endocrinology, has a decidedly limited usefulness.

The Modern Method of Birth Control By Thurston Scott Welton. M.D. F.A.C.S. Cloth. Price \$3. Pp. 159 with illustrations. New York: Walter J. Black, Inc., 1935.

In this book the author offers an ingenious series of charts and a celluloid wheel together with brief explanation of the so-called safe period and practice of this method in relationship to birth control. Dr. Welton is inclined to believe that the method has value. He discusses the literature pro and con emanating from various places. His book should be most useful to those who care to try this method.

L'examen du malade Guide olinique de l'étudiant et du médecin Médecins chirurgis obstétrique neurologie et spécialités. Par P Delmas professeur à la Faculté de médecine de Montpellier et al Paper Price 30 francs Pp 318 Paris Masson & C^{ie} 1935

The scope of this elegant little book is to serve as a guide for a novice writing histories and examining patients. Nine specialists in their respective lines collaborated in preparing chapters on examination of medical, surgical, obstetric, pediatric, dermatologic, gynecologic, neurologic, otorhinolaryngologic and ophthalmologic cases. These subjects are supplemented by a chapter describing simple laboratory examinations that can be performed by a general practitioner in his office. The compendium is frankly a student's manual for systematic questioning and physical examination of patients and does not pretend to be a diagnostic guide. The subject is presented in a succinct manner teaching the student to gather and correlate observations and thus arrive at a correct diagnosis. The book is a valuable addition to the library of French students.

The Scientific Basis of Evolution By Thomas Hunt Morgan Ph.D D.Sc LL.D Second edition Cloth Price \$3.50 Pp 306 with 46 Illustrations New York W W Norton & Company Inc 1935

The Nobel prize winner in medicine here presents lectures given at Cornell University in the spring of 1931, revised and modified to include newer studies in the field of genetics. His book explains in language understandable certainly to any physician the scientific studies that have led to our present views regarding the origin of species and the evolutionary process by which human beings came upon the earth.

Medicolegal

Dental Practice Acts Circuit Court's Holding of Unconstitutionality Excuse for Licentiate's Violating Act—Hunt was prosecuted for practicing dentistry in Florida without a license. He brought habeas corpus proceedings and was discharged Jan 11, 1933, the circuit judge before whom the proceedings were pending holding that the Florida dental practice act was unconstitutional. On appeal, however, the Supreme Court of Florida, division A, March 24, 1933, reversed the circuit court's holding (109 Fla 248, 147 So 282), *THE JOURNAL* (Jan 20, 1934, p 239).

Apparently, before the Supreme Court had passed on the constitutionality of the dental practice act but after there was a "circuit court adjudication that the entire law was unconstitutional and void," Williams, a licensed dentist employed and permitted Hunt to practice dentistry in his offices. After the Supreme Court's decision the board of dental examiners revoked Williams' license, relying on a provision of the dental practice act which authorizes revocation if a licentiate employs, allows, or permits an unlicensed person "to perform unauthorized dental work in his dental office." Williams brought mandamus to review and reverse the board's action. The trial court denied him relief and he appealed to the Supreme Court of Florida, division A.

The dental practice act contains no provision authorizing an appeal to the courts from a decision of the board of dental examiners in revocation proceedings. Apparently some question was raised in view of that fact as to Williams' right to bring mandamus. A state, said the Supreme Court, may validly create a statutory tribunal, such as a board of dental examiners, may grant to it the final determination of whether or not licenses shall be revoked for causes set forth in the law, and may confer on it power to decide legal questions necessarily arising in the course of its proceedings. For such a statute to accord the due process of law guaranteed by the state and federal constitutions, it is not necessary that that statute expressly provide for an appeal to the courts. However if no method of judicial review is provided for in the statute, mandamus is the appropriate remedy to enable the courts to review the record to ascertain whether or not the tribunal correctly applied the law to the facts of the case and whether or not the record as a whole discloses an abuse of delegated authority or arbitrary or unreasonable action.

In the opinion of the Supreme Court, the board of dental examiners in revoking Williams' license misapprehended the applicable law. The dental practice act in authorizing the revocation of the license of a licentiate guilty of employing, allowing, or permitting any unlicensed person to perform any work in his office which under the provisions of the act can only be legally done by persons holding a license to practice dentistry, the court held, has reference only to a conscious and culpable act on the part of a licentiate amounting to a wilful design to do that which is denounced as unlawful. The provision in question has no reference to an act done by a licentiate in recognition of the supposed correctness of a judicial decision of a competent court declaring the acts prohibited by the statute not to be unlawful because of the alleged unconstitutionality of the statute denouncing those acts. While it would be no defense, the court said, for a dentist to show in justification of his unlawful acts that he deliberately violated a valid statute believing in good faith that the law was unconstitutional, yet it is a defense for him to show that in violating the act, i. e., in employing an unlicensed person to practice dentistry, he placed reliance on the decision of a competent court that the statute was unconstitutional. The Supreme Court held, therefore, that the board of dental examiners was not warranted in law in revoking Williams' license to practice and reversed the action of the board revoking his license.—*State ex rel Williams v Whitman et al, State Board of Dental Examiners (Fla), 156 So 705*

Optometry Practice Acts Right to Register After Continued Failure to Register Annually—The North Carolina optometry practice act (C. S. Code 1931, sec. 6696) requires an optometrist to renew his license and to pay a registration fee to the board of examiners in optometry annually prior to April 1. If he neglects to do so his license may be revoked by the board after notice and hearing, but a license may not be revoked if a holder "shall pay, before or at the time of consideration, his fee and such penalty as may be imposed by the board." Mann, a licensed optometrist, paid the required fee and renewed his license annually until 1913, when he discontinued the practice of optometry. The board never instituted an action to revoke his license. In 1931, when he attempted to renew his license, by tendering the annual fees he had failed to pay since 1913, the board, contending that he had abandoned his license, insisted that he be reexamined. He then instituted proceedings in the superior court, Wake County, to compel the board to renew his license without requiring him to submit to examination. The trial court denied him relief and he appealed to the Supreme Court of North Carolina.

Revocation, said the Supreme Court, being the only method prescribed by the optometry practice act for depriving a licentiate of his right to practice optometry, is the only way a licentiate can be deprived of that right. He is not deprived of his right to practice merely because he has failed to practice over a period of years. Since revocation proceedings were never instituted, Mann is still a licensed optometrist and has the right to have his license renewed on the payment of the delinquent fees and the statutory penalty.—*Mann v North Carolina State Board of Examiners in Optometry (N C) 175 S E 281*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Thomson's Disease. Myotonia Congenita. B. I. Comroe. Philadelphia—p. 714.

Histopathology of Hematopoietic Tissues in Hemophilia.—Custer and Krumphaar studied three cases of hemophilia, one died as the direct result of hemorrhage, another of a combination of infection and hemorrhage and the third of infection without any relation to hemorrhage. The subjects were of about the same age. The cytology of the bone marrow is presented in detail, especially that of the megakaryocytes which are generally regarded as the originators of the blood platelets and directly concerned with blood coagulation, the major disturbance in hemophilia. The state of the thrombocyte series in the bone marrow was the striking feature in all three cases. Estimations of the incidence of this series of cells in approximately 12,000 cells per bone were compared with similar estimations in a group of nonhemophilic controls. The differences indicate the need for an estimation covering a much larger number of cells than the usual differential count of 500 or even 1,000 in categories that are sparsely represented. The relative percentage in the three hemophilic patients was fairly uniform. An average in hemophilia of 57.3 cells of the megakaryocyte series per 12,000 total cells opposed to 29.7 in eight nonhemophilic controls is regarded as significant. The largest percentage of megakaryocytes appeared in the purely hemorrhagic case, the smallest in the purely infectious and a midposition was held by the case in which hemorrhage was a minor factor, the increased incidence of megakaryoblasts, evidence of regenerative activity, was associated with hemorrhage, matched only by the apparently recently hyperplastic femur in the infectious case, in which the increase in young forms was offset by the sparsity of degenerate cells. The morphology of megakaryocytes in this disease does not vary from the normal. The megakaryoblast is seen as a hypertrophic, moderately basophilic cell which may be strictly mononuclear or may exhibit early nuclear polymorphism, nuclear

lobes occasionally appearing to lie one on the other, the vague acidophilic granularity is rarely seen in this stage. The normal adult megakaryocyte presents a more or less vesicular nucleus which is multilobated with a sharp perinuclear membrane, fine chromatin strands and prominent nucleoli lying in a large cytoplasmic mass with a pale basophilic background and extremely delicate pink-staining granules. The degenerate cell is characterized by a shrunken or faded nucleus and a frayed vacuolated cytoplasm which stains poorly. On four occasions it was possible to demonstrate the so-called "Wright's figures," i. e., cytoplasmic buds of megakaryocytes which extend through the wall of a blood sinus into the lumen, confirming J. H. Wright's observations on the mechanism of platelet formation, two such cells are pictured. Formation of erythrocytes and granulocytes in all three cases conformed strictly to normal standards. Erythropoiesis seemed rather more active in the flat bones than one usually finds except in the severe anemias. No structural abnormality of blood vessels was demonstrated. The accessory blood forming organs showed no significant changes although an increased prominence of cells of the reticulo endothelial system was noted in each case, there was no evidence for or against the autochthonous formation of the megakaryocytes seen in the spleen of the first case.

Chronic Granulocytopenia.—Stealy presents a case of chronic primary granulocytopenia which has been under observation for five years. The symptoms, history, physical observations and blood counts during the acute attacks and during the periods of remission present a typical picture of the chronic primary type of the disease without ulceration. On three occasions an increase in neutrophils was noted a few hours before, after or at the same time the total leukocyte count started to fall. The fall of the neutrophil count from this higher point was abrupt and caused a complete reversal of the neutrophil-lymphocyte ratio. It is possible that such an increase in neutrophils may be used as an indicator of an oncoming acute attack. Drugs of the benzene ring were discontinued after the first acute attack in 1929. Pentnucleotide was given in two of the most severe attacks. The rise in the leukocyte and neutrophil count corresponded to the results apparently obtained by its use by Jackson. Only supportive measures were used during other less severe attacks. During the periods of remission various forms of medication have been tried. Concentrated forms of vitamins B and D, in addition to a well balanced diet, have been given empirically since June 1934. During this time there has been apparent improvement in subjective symptoms and a rise in the general level of the leukocytes and the neutrophil-leukocytes to within normal limits. This line of treatment is being continued on the basis that granulocytopenia may be a deficiency disease in the same way that pernicious anemia is one.

Cytoplasmic Changes in Peripheral Neutrophil.—Meranze and his associates present the subject of toxic cytoplasmic alterations in peripheral neutrophils. These changes have been shown to be of value diagnostically. They are most uniformly found in infections, and probably their greatest value lies in differentiating localized from generalized infections or the development of complications, whether this is a secondary infection or a spread of the initial infection. These changes are most uniformly found in pneumonia, peritonitis, bacteremias and septicemias. The addition of toxic cytoplasmic changes in the neutrophils to the hemogram in which they were previously absent should suggest an added complication. From a prognostic point of view an increasing degenerative index lends increasing gravity to the outcome. The addition of this examination as a routine to the hemogram is of clinical value, often gives more information than the total leukocyte count and, if followed serially is often more informative than the Arneith-Schilling shift. No hemogram in infection or in serious disease states is complete without the determination of toxic cytoplasmic changes and their recording in some quantitative scheme, such as Rosenthal's "degenerative index." Cytoplasmic changes in the peripheral neutrophil consist of an alteration of the staining quality of the cytoplasm and its components from a normal eosinophilic pink to a dirty gray or blue and an increase in granulation. In the abnormal neutrophil the cytoplasmic granules are coarse irregular in distribution, staining a deep blue and oxidase negative. They may be sparse, grouped on one

side, or diffusely scattered over the entire protoplasm. All the neutrophils are not uniformly granulated. In some the granules may be so large that the cell may be mistaken for a basophil. Vacuolization of the cytoplasm is usually observed, giving the cells a moth eaten appearance about the periphery or throughout the cytoplasm.

Influence of Diet on Edema in Arthritis—Scull and Pemberton direct attention to the fact that convalescence from arthritis is frequently characterized by a reduction of swelling

of the soft tissues, particularly evident though rarely conspicuous in the hands, and concurrent with a diminution of pain and increasing range of motion of the joints. Approximate water balance estimations indicate that a net loss of water from the body accompanies a subsidence of swelling of tissues, pain and limitation of motion. Disturbances of water distribution in tissues constitute significant factors in the dynamic pathologic changes of the rheumatoid syndrome. The administration of several types of low calory diets has been shown to be associated with a net loss of water and with clinical improvement. Dehydrating diets, adequate in calories, high in protein, low in fluid and high in fat induced a net loss of water from arthritic patients with clinical evidence of improvement, and the authors suggest that the relative increase of fat and protein metabolized on low calory diets exerts a significant influence in the striking clinical results frequently achieved. Recumbent rest is considered as acting, in part, by favorably influencing a shift of fluid from the tissues to the blood and lymph channels. A negative water balance contributes to recovery from both atrophic and hypertrophic arthritis. This suggests that both types of arthritis arise in part from similar or comparable premises and, further, that rigid restriction of many therapeutic measures, especially the foregoing, to one type alone is unwarranted. Dehydrating measures alone do not constitute a therapeutic escape from arthritis. Vigorous sweating, purgation or diuresis have long been known to be of only limited value and even dangerous. So far as changes in the distribution of tissue fluids in arthritis may be desirable, they should be achieved by the more sustained and "physiologic" influence and measures discussed.

- Clinical Test for Intradural Spinal Lesions—Naffziger and Jones call attention to a clinical test that has enabled them to differentiate radicular pain of intradural origin from extradural pain of radicular type. In cases of gross space-consuming lesions within the spinal canal, radicular pain commonly is caused by tension or traction on sensory roots. In lesions of the cauda equina, pain, particularly of the bilateral sciatic type

produced by coughing, straining, sneezing or muscular movements, has long been known to be characteristic. It is well known, however, that muscular movements, straining or any sudden effort, such as coughing or sneezing, may give rise to pain in patients with scirrhus resulting from lumbosacral, sacroiliac and other lesions of extradural origin. When the test is performed the patient is placed in a comfortable position, and when he is free from pain the cervical veins are compressed as in the Queckenstedt test. As the intracranial and intraspinal pressure above the level of a block is raised the typical radicular pain is reproduced because the tumor or other gross lesion presumably is displaced sufficiently to cause traction on or irritation of a nerve root. Although the radicular pain most often is reproduced on compression of the jugular and other cervical veins in certain instances, depending presumably on the direction in which the tumor dislocates most readily, such pain may be experienced only on the sudden release of the jugular compression. It is easy to understand the dislocation of a pedunculated neurofibroma with its traction on a sensory root occurring as a result of this test, but in addition the test was found to be positive in association with other gross lesions, such as spongioblastoma multiforme of the conus medullaris, hemangio-endothelioma involving the cauda equina and conus medullaris, and arachnitis serosa circumscripta of the fourth thoracic segment. If the test is positive, it furnishes presumptive evidence of the presence of a gross, space-consuming intradural lesion. A positive reaction may not be obtained in all persons with tumor of the spinal cord. Another sign of diagnostic value was present in two of the authors' four cases. When the needle encountered dural resistance at the time of lumbar puncture, the patient experienced excruciating pain. In one case the fluid was obtained on puncturing in another interspace, but in the other case, regardless of the interspace used, pain was so intense that it was necessary to employ general anesthesia in order to complete the puncture. In each instance a tumor was found anterior to the roots of the cauda equina, displacing the roots posteriorly against the dura so that they were immobile and under tension. The slightest pressure on the dura irritated the immobile nerve roots, causing pain. In a suspected case of tumor, therefore, severe pain produced during a lumbar puncture is suggestive. In two of the cases reported the slow-growing nature of the tumor produced definite bony alterations that were demonstrated roentgenographically.

Cortical Cerebellar Atrophy.—Parker and Kernohan discuss the possibility of a virus disease with a special affinity for the Purkinje cells, which attacks younger patients, runs a much more rapid course and is associated with general weakness and prostration. This disease shows certain analogies to chronic anterior poliomyelitis, to Parkinson's syndrome of epidemic encephalitis and to the disease known as "Jouping ill" in animals. The case of Murri and that previously reported by them may fall into this category; their present case suggests even more strongly the possibility of a virus infection. The clinical picture was that of some general noxious condition that caused the patient to lose strength and weight and that also had a specific influence on his cerebellar system, in that it was conspicuously injured. The whole illness from onset to death lasted almost twelve months. It was insidious in onset and steady in progress and seemed in general to present a fairly clear cut clinical syndrome. Microscopically there were processes still active, which with good reason could be called encephalitis. The lesion in the hemispheres was more advanced and thus possibly older than that in the vermis, where signs of encephalitis were most marked. Theoretically the perivascular collections of cells might be the result of tissue degeneration, but the other observations suggest an inflammatory cause for the degeneration of the cells. The reactions in the cerebellum corresponded to those associated with virus disease in general and here were limited to the cerebellum alone particularly to the Purkinje cells, even the fiber tracts to and from the cerebellum were intact. In suggesting a virus as the etiologic agent in some of these cases of atrophy of the cerebellum, the authors recognize that they depended on histologic signs alone. Nevertheless, considering the clinical course and the pathologic changes at least in their present case, they think that there is sufficient evidence to suggest

strongly that the condition is a virus disease. The two other cases one described by them and the other by Murri, could also fit into this category by reason of the subacute nature of the process. The remaining eleven cases, by reason of the chronicity of the disease, do not justify such a hypothesis unless one accepts a chronic type of virus disease and rejects all other possibilities.

Nephrosclerosis and Urinary Obstruction.—Milles prefers the term benign nephrosclerosis or benign arteriolar sclerosis of the kidneys to chronic interstitial nephritis. The condition is primarily due to an arteriolar spasm of the renal vascular bed which may be local or part of a general condition and of the nature of a fatigue reaction. As the process continues hypertrophy or degeneration of the vessel wall, or both, results. Thus the muscular elements in the media hypertrophy, the intima proliferates and finally a gradually developing ischemic degeneration sets in. The resulting hyaline changes and fibrosis in the intima, media and adventitia produce more or less complete occlusion of these important vessels. The rate of the process varies but is usually extremely slow. With the gradual interference with the blood supply the tubular epithelial cells undergo slowly progressive atrophic degeneration and the less differentiated and metabolically more sluggish cells of the connective tissue proliferate. Concomitantly, the glomerular tufts degenerate and are replaced by hyaline scar tissue. The result is obliteration of a percentage of the glomeruli, atrophy of the tubules and proliferation of the interstitial connective tissue. Round cell infiltration in the interstitial tissue occurs secondarily as an incidental process, the result of either degenerative changes or the acute changes occurring with renal decompensation. In the presence of a slowly progressive process which involves destruction of glomeruli the surviving glomeruli must function twice as actively in order to maintain renal compensation. Any additional strain placed on the kidneys may dissipate the reserve, and then actual renal decompensation ensues. Reduction in the available oxygen such as would result from heart failure with its attendant circulatory failure and drop in blood pressure, would accomplish this. Similarly, mechanical obstruction to the outflow of urine, such as occurs in prostatic hypertrophy with obstruction, places an added burden on the urine secreting mechanism.

Changes in Mixed Tumors of Kidney After Roentgen Therapy.—Bothe studied two mixed tumors of the kidney that were irradiated before surgical removal in order to determine the tissue changes. Although both patients died within a short time following the removal of the tumor, the microscopic studies show very definite change of the tissue in the tumors which was undoubtedly due to the irradiation. The embryonal sarcomatous cells of mixed tumors of the kidney are radio sensitive. The epithelial cells in mixed tumors of the kidney are radioresistant. When mixed tumors of the kidney are irradiated before surgical removal, the tumor is usually reduced in size. The reduction in size of the tumor following irradiation appears to be dependent on the amount of embryonal sarcomatous tissue. Irradiation of the tumor does not completely destroy all the malignant cells. Mixed tumors of the kidney should always have sufficient preoperative irradiation. They should always be removed after irradiation. Surgical procrastination results in subsequent growth and metastasis.

The Allergic Child.—Stoesser and Shaperman review the treatment carried out in 141 children having such allergic disorders as eczema, coryza, hay fever, asthmatic bronchitis and bronchial asthma, urticaria and gastro-intestinal allergy. They belong to that section of a newer classification of allergy entitled natural or atopic hypersensitiveness characterized by a strong hereditary tendency. A large number of patients

received relief. In obtaining this result, no elaborate methods of diagnosis were used, but instead a few rather simple procedures were followed. Treatment involved the thorough removal of the offending foods from the diet, or the irritating inhalants from the child's environment. Pollen allergy responded well to proper and careful desensitization. A small number of patients required surgical treatment to obtain relief. Success depended on the avoidance of all haste in the diagnosis and treatment. Delays in relieving the child were often necessary because histories had to be retaken, cutaneous tests repeated and trial diets rearranged. A rather exhaustive search was conducted for the offending allergen or allergens, and an effort was made to avoid placing the patient on some form of drug therapy, thereby dismissing the search.

Meningitis Caused by Filtrable Virus—Rivers and Scott observed two men in whom an illness developed that was characterized by headache, vomiting, stiff neck and a high cell count, 1,700 and 720 per cubic millimeter, respectively, in the spinal fluid. The cells in the fluid were practically all mononuclear elements. Both patients made a slow uneventful recovery. The clinical pictures presented were almost identical and suggested a virus meningitis. Consequently, spinal fluid from each of them was inoculated intranasally, intraperitoneally and intracerebrally into six Swiss albino mice. By means of emulsions of bacteriologically sterile brain material injected intracerebrally into mice, the active agent has been passed serially through ten lots of mice and at present small amounts of a 10 per cent emulsion of infectious brain material kill practically all the mice in seven days. An active agent free from bacteria was obtained by the inoculation of a patient's spinal fluid into Swiss mice. The virus has been passed through nine sets of mice and reinoculation experiments clearly show that both strains are immunologically identical. The results of the experiments indicate that the virus obtained from the spinal fluid collected from the two patients is pathogenic for man. Two mice that received spinal fluid and recovered and five that received spinal fluid and did not become sick were later found to be solidly immune to the virus introduced intracerebrally. Neutralization tests conducted in mice and guinea-pigs show that serum collected from the patients at the beginning of their illness fails to neutralize the virus, while serum collected late in convalescence does inhibit its activity. The authors' virus is not similar to any active agent heretofore described, with the exception of those of Armstrong and Lillie and Traub.

Atelectatic or Compensatory Bronchiectasis—Findlay reviews the history of atelectasis in the production of bronchiectasis. The view that the bronchiectasis accompanying pulmonary collapse is compensatory in nature is supported. The specific cause is the inability of the lung to fill the thoracic cavity and hence the necessity for some space communicating with the external air (alveolus or bronchus) to dilate. The significance of the so-called triangular shadow in the roentgenogram occupying one or the other diaphragmatico-vertebral angle is discussed. This shadow is shown to be caused by encysted effusions, fibrosis of the lung and thickened pleura, pneumonic consolidation and collapse of the lung. Stress is laid on the re-inflatability of the lung as essential for a diagnosis of pulmonary collapse. Some previously recorded cases of atelectatic bronchiectasis are considered and the correctness of the diagnosis is submitted to criticism. Three personally observed examples of bronchiectasis with an accompanying triangular shadow are described. In all, the bronchiectatic lesion was situated at the right base, was of mild degree and was completely recovered from. In one the shadow was certainly due to collapse of the lung, and it is concluded that this was the cause of the bronchiectasis. In another case collapse was the probable cause, and in the third case pneumonic consolidation appeared to be the more likely etiologic factor.

Gastric Secretion in Celiac Disease—Ogilvie gives the results of gastric analysis in a series of seventeen cases of celiac disease which confirm the observations of other workers that there is impaired secretion of free hydrochloric acid in the stomach but that true achlorhydria does not occur. There was no diminution in peptic activity, but a slight prolongation was noted in the emptying time. The total chloride was increased, a finding that is presumably the result of the greater concentration of chloride in the blood, which is to be attributed to the decrease in the red cell count and the increase in plasma. The hypochlorhydria is probably an important etiologic factor in the production of hypochromic anemia in patients with celiac disease.

Blood Transfusion in Malnutrition of Infancy—Thomson illustrates that, in the marasmic infants whose constitution is such that neither skilful feeding nor expert nursing can coax them to health, blood transfusion is a worthy adjunct to routine methods. Used as an emergency measure in the extreme stages of enteritis, the results are often disappointing. The fact that one such patient, apparently moribund when transfusion was done, is now a healthy baby indicates that all measures should be tried even when the cause seems lost. The author's group of twenty cases in which blood transfusion was employed soon after the onset of enteritis shows distinctly favorable results. When the condition of malnutrition remained uncomplicated, blood transfusion led to an immediate and sustained gain in weight. These infants had failed to respond to routine treatment over a long period. No addition to the treatment was made either following the transfusion or for some days previous to it. Five patients with severe enteritis died. All the others to whom blood was given have subsequently done well. The results indicate that in most cases blood transfusion does supply a stimulus to the marasmic infant. Blood transfusion may act by supplying physiologic fluid by supplying a deficiency of one or more of the solid contents of the blood and/or by exciting a tissue response in the bone marrow or elsewhere. In most of the cases one of the parents acted as donor, and in every case the recipient's serum was tested directly against

the donor's corpuscles. The serum and corpuscles were left in contact for twenty minutes before a decision was made on the compatibility of the bloods. In two instances the baby's serum agglutinated the mother's corpuscles, and one of these was a baby aged 6 weeks—an indication of how early in life the blood groups may be distinctly differentiated.

Induction of Labor by Means of Estrogenic Substance—Robinson and his associates believe that their animal and clinical results support the view that estrogenic substance is the main sensitizing factor of the human uterus. They find that it is impossible to overcome the inhibitory phase of the normal pregnant uterus by the injection of large quantities of the nonstimulating factors and that the hormone balance in normal pregnancy in the human being is not maintained simply by the relative quantities of progesterin and estrogenic substance. They were unable to procure abortion by means of the material. Their clinical results have shown that when the substance is administered near term it may or may not induce premature labor but that it is not a reliable means of induction. It is an especially unsuitable method for cases in which it is necessary to bring on labor immediately because of the uncertain interval (up to seven or eight days) that intervenes between the commencement of treatment and the onset of expulsive contractions. Their experience has demonstrated that estrogenic substance is the best method of evacuating the uterus in cases of missed abortion or intra-uterine death of the fetus. The method, when correctly carried out, is successful in at least 80 per cent of cases, and it has the additional merit of being free from risk. The patient has the discomfort of several intramuscular injections, but she is immune from the danger of uterine trauma, infection and hemorrhage. The substance may prove of value in dealing with primary uterine inertia, as the authors' results have shown that the response to the therapy is dramatic and that it entails no risk to either mother or child. This treatment is at present expensive, but so far no attempt has been made to determine how little or how much of the hormone is required for therapeutic use, and it is quite possible that the amount being used may be unnecessarily large.

Unusual Case of Heart Block F. W. Preston —p 825

Ligation of Splenic Artery for Splenic Anemia—Watson cites a case of splenic anemia in which ligation of the splenic artery was followed by general improvement. There was a history of splenomegaly for nineteen years. He states that the value of ligation of the splenic artery is apparent in that the case was seemingly hopeless. Rapid reduction in the size of the spleen took place gradually and the interval between tappings was increased. The improvement in general health has continued for more than three years after operation. There was apparent recovery of the liver. Ascites was present for six months prior to operation. Thrombosis occurred on the seventh day. Platelet counts were not made before operation.

Ligation of the splenic artery is apparently a safe procedure, provided it is done sufficiently far from the spleen to avoid interference with the communication between the splenic and left gastro-epiploic arteries.

Treatment of Malaria with Atabrine Musonate—Blaze and Simeons treated twenty-one malaria patients with atabrine musonate an atabrine salt of musonic acid, soluble in water. Its intramuscular injection in therapeutic doses does not give rise to toxic symptoms. While a single injection of 0.375 Gm. has in some cases a remarkable effect on the clinical picture, a recrudescence usually occurs within a few days. Heavy malignant tertian infections are only slightly influenced. Two injections of 0.375 Gm. given on successive days are sufficient to control the temperature within forty-eight hours, and in a maximum of four days all forms of benign tertian parasites and the ring forms of malignant tertian parasites disappear. Crescents appear to be in no way influenced and must be destroyed by plasmodochin. In some cases there is a reappearance of parasites in the blood after a few days, but they disappear spontaneously. In no case has there been a return of fever after two injections. The intravenous route though harmless is not satisfactory for routine treatment. The immediate results of treatment with atabrine musonate justify a preliminary report, but the authors state that the period of observation has not been long enough to enable them to compare the rate of relapse after atabrine musonate with that after oral atabrine or quinine.

*Attempt at Substitution of Vaccinotherapy by More Practical Method
S Golovine —p 579

New Treatment of Cerebral Hemorrhage—Colella and Pizzillo report observations on thirty-five patients with cerebral hemorrhage. The method of research consisted primarily in precision of diagnosis and close observation of the symptoms before, during and after the intramuscular injection of the patients own blood. Especial attention was given to the comatose state, arterial pressure, muscular power and capacity for movement. The technic of treatment consisted in the removal of from 25 to 30 cc of venous blood and its immediate reinjection in the gluteal region of the well side. If immediate injection is impossible a few cubic centimeters of sodium citrate should be aspirated into the blood to prevent clotting. The authors report seven cases in detail. All the patients with cerebral hemorrhage did not obtain an equally rapid improvement of the lesion, but all or almost all had a return of consciousness often during the course of injection of blood, and all had a more or less rapid and complete return of their capacity for movement. Even old lesions can be favorably influenced to a varying degree. The theories brought forward to explain the action of autohemotherapy are multiple and indefinite. Even though adequate theoretical explanation is now impossible, the authors believe that the practical aspects are indubitable.

Substitute for Vaccinotherapy—Golovine describes a method of automicrobiotherapy which can be carried out without extensive bacteriologic equipment. For patients in whom the pathogenic organism is found in the urine, the technic is as follows. From 15 to 20 cc of urine is centrifugated, the supernatant fluid decanted, and the centrifugate resuspended in about 5 cc. of sterile physiologic solution of sodium chloride. Sterilization is obtained by adding two drops of iodized alcohol per cubic centimeter of liquid. In a few minutes it is ready for injection. Injection is subcutaneous or intramuscular and the first is with 0.25 or 0.5 cc. The technic for other conditions, i. e. furunculosis, soft chancre, and so on, consists in removal of the material from the lesion by means of a sterile platinum loop to 5 cc of sterile physiologic solution of sodium chloride until the liquid is thickly turbid. After this the technic is the same as for the specimens of urine. The results of the treatment are as good if not better than those obtained with autogenous vaccines, and the method is one that can be followed in the colonies or other regions in which careful bacteriologic isolation and culture are impossible.

Intestinal Occlusion Case Ho Dac Di and Huynh Tien Doi —p 629

Cholecystitis and Colon Bacillosis—Jacquet and Thieffry were struck by the frequency with which unrecognized cholecystitis was associated with known colon bacillus infection or even simple colon bacilluria. After studying all colon bacillus infections systematically they reached the conclusion that the gallbladder and biliary passages act as a reservoir of infection for the production of bacteria. Hence, they play a definite part in the persistence of colon bacillosis and its frequent incurability.

Blanching Phenomenon in Scarlet Fever—Dumitresco reviews the definition, frequency, significance, mechanism and theoretical basis and makes some personal observations on the skin blanching which occurs in scarlet fever. As a result he concludes that there is a definite analogy between the blanching caused by convalescent serum, normal serum and Dick's anti-carlatinal serum. The only difference is that with calcium

chloride the blanching is produced over a smaller surface and in a less intense manner. In general, the phenomenon is produced over a wider surface by the weaker dilutions (1 or 2 per cent) than by more concentrated solutions (5 or 10 per cent).

Tuberculous Infection of Nursing by Short Lived Contact A Vaillette
and B Rosenkranz —p 179

Treatment of Bronchopneumonia in Infants—Rohmer and Tassovatz treated bronchopneumonia in infants by means of citrated blood transfusions. The first step of their technic consisted in collecting the blood from the donor. The 100 to 120 cc of blood necessary was collected in a 300 cc. cylindric tube containing 0.8 Gm of sodium citrate per hundred cubic centimeters of blood. The second step was the exsanguination of the infant. This was accomplished by withdrawing blood from the lateral sinus in infants or from the veins of the elbow in children aged more than 1 year. The amount of blood withdrawn depended on the severity of the disease process in less severe processes only a small portion need be withdrawn, but in toxic-infectious cases the amount withdrawn should almost equal the quantity to be injected. The final step, the injection of blood, was made directly after the bleeding. The injection was made slowly—about 20 cc each five minutes. During the course of injection it was necessary to watch the pulse, respiration and facies of the infant. The mode of action of transfusions in infectious states is not known. It appears, however, to be multiple and affects the general condition, the temperature, the cardiovascular system and the anatomic lesions of the respiratory apparatus. Simple bronchopneumonia recovers without transfusion. In the more complicated and severe forms transfusion sometimes repeated three or four times, results in a marked decrease in mortality. In this group the authors obtained a statistical decrease in mortality from 70 per cent in untreated cases to 30 and later 20 per cent of the treated. Serious accidents may occur and the authors recommend the preventive injection (one hour before the transfusion) of camphorated oil and epinephrine-hypophysum and to repeat this in severe cases at the end of the transfusion.

Erythema Nodosum with Negative Tuberculin Reaction—In the Scandinavian countries, according to Landorf, about 97 per cent of the cases of erythema nodosum can be definitely connected with tuberculosis by means of the roentgen ray or the tuberculin test. In this report, however, he studied a group of children with erythema nodosum who failed to give any evidence of tuberculosis even when tested with tuberculin in high doses. These observations reject the idea that erythema nodosum without sensitivity to tuberculin can have the same etiology as erythema nodosum possessing a high degree of sensitivity to tuberculin and accompanied generally by unquestionable manifestations of tuberculosis. One case, cited in detail, offers strong evidence that erythema nodosum may occur in children not affected with tuberculosis as a nonspecific allergic symptom.

Giannelli —p 302

Hyperplasia of Plantar Aponeurosis in Lesions of Sciatic Nerve Case
R Liberti —p 319

Action of Parathyroid Extract on Carbohydrate Metabolism—Ferrannini studied the action of parathyroid extract on glycemia of normal persons. He carried out his investigations in three groups of individuals. In one group he investigated the action of parathyroid extract on glycemia in another its

action on sugar tolerance and in the third the relation that exists between the action of parathyroid extract and that of epinephrine on glycemia. From the results of his investigations the author concludes that parathyroid extract produces a decrease of glycemia, which oscillates between 13 and 56 per cent. These results were seen in almost all cases (thirteen out of fourteen). Parathyroid extract produces also an increase in the tolerance to carbohydrates. Its action on glycemia is similar to that of insulin.

Ptosis of Upper Eyelid—Under the name of "ptosis palpebralis consensualis," Giannelli reported, in 1906, the following phenomenon. In producing passive closure of the eye with normal vision in certain persons suffering from unilateral amaurosis, the upper eyelid of the amaurotic eye would also close. On covering the normal eye with a protector, both upper eyelids would lie lowered. The author reports four new cases in which he observed this phenomenon. In one case, left hemiparesis and conjugate deviation of the eyes to the right existed simultaneously (Foville's syndrome). The phenomenon disappeared with the syndrome by antisyphilitic treatment. In another case, the author made a serial examination of the encephalon. He reviews the anatomicopathologic literature on the nervous supply of the different ocular muscles especially that of the levators of the eyelids. He shows the lack of agreement in the opinions of observers as well as in those of experimenters in relation to the site of the nervous lesion causing ptosis of the upper eyelid and in this connection he emphasizes the importance of one of his clinical cases, in which the palpebral condition coexisted with Weber's syndrome of the Foville type. He concludes that the loss of sight in one eye is not necessary for the development of palpebral ptosis, that there is no relation between the presence of ptosis and the ability to close the eye voluntarily and that the type of palpebral ptosis described is a form of supranuclear paralysis localized in the ventral proximal portion of the pons or in the immediate vicinity of the distal part of the nuclear column of the third pair of nerves in such a way that the corticonuclear channels through which the antagonistic action of the nerves on the levator and the orbicularis is conducted are interrupted and result in the production of the palpebral phenomenon.

Eclampsia and Weather F Jacobs—p 255

*Connection Between Eclampsia and Changes in Weather A von Latzka—p 286

Bacteriology of Uterus During Puerperium—Smorodintzeff and his associates show that the generally accepted theory that the uterus of puerperal women without fever is infected after the fifth day must be revised. They show that the erroneous conclusions reached by most investigators are due to an incorrect evaluation of the bacteriologic changes, to the neglect of a qualitative and quantitative analysis and to the imperfection of the method of withdrawal of specimens of the uterine contents. The authors withdrew on different days of the puerperium specimens of lochia in seventy-five puerperal women. They obtained the lochia with the improved method of Dertschinsky (THE JOURNAL, January 19, p 268), subjected the specimens to quantitative and qualitative analysis and found the uterine contents sterile in the majority of puerperal women who were free from fever. However, in puerperal women who had fever they found that the uterine cavity contained large numbers of bacteria, primarily streptococci and staphylococci. Döderlein's opinion that there is a parallelism between the clinical course of the puerperium and the bacterial contents of the uterine cavity was corroborated by their observations.

The Weather and Labor Pains—The statistical analysis of a large material convinced Jacobs that birth and death are to a certain extent determined by the weather. In studying the part played by meteorologic factors, he gave especial attention to the atmospheric pressure and the temperature. He

detected an especially close connection between the life processes and the temperature and shows that the "retardation" in the biologic curves in relation to the atmospheric pressure can largely be explained from the course of the temperature. However, the author concedes that all meteorologic elements, even those disregarded in this study, are interrelated and that therefore the results reached by him are not final. He found that a considerable decrease in the mortality curve accompanies a considerable decrease in the birth and temperature curves and follows shortly after a reduction in the atmospheric pressure.

Eclampsia and Changes in Weather—In reviewing the eclampsia material of the women's clinic of the University of Budapest, von Latzka gained the impression that the incidence of eclampsia is highest during the months of June, July, August and September. A study of the meteorologic conditions disclosed that the twenty-six cases of eclampsia, which were admitted to the clinic since 1931, all were meteorotropic. However, studies on the material from other clinics disclosed the absence of such a relationship in almost 10 per cent of the cases. It appears that the eclamptic attacks of hepatogenic and cerebral origin are independent of the changes in the meteorologic conditions.

*New Method of Obtaining Prostatic Tissue for Biopsy H Viethen—p 361

*Experimental Contribution to Origin of Intestinal Ulceration (Duodenum) S Stelzer—p 399

Method of Biopsy of Prostate—According to Viethen, biopsy on the prostate has been but seldom carried out because of the difficulty of the transvesical, perineal or rectal approach. The easiest approach is by way of the urethra. This was made possible by electrotomy instruments so constructed that the active electrode excises rather than incises the tissue and that the current employed cuts rather than coagulates. In diagnosing the tissue thus obtained, one must bear in mind the characteristic alterations produced by the current, such as enlargement of nuclei and of cells, and the frequent tearing away of glandular duct epithelium. The endo-urethral method of biopsy is indicated when the differential diagnosis between inflammatory conditions, tuberculosis, hypertrophy or carcinoma cannot be made on clinical data. With proper technique the procedure is devoid of danger or later complications. It was successfully carried out in the Münster clinic (Prof H Coenen) on forty patients.

Origin of Intestinal Ulceration—Stelzer made a Pavlov pouch in dogs from the infrapapillary portion of the duodenum and introduced a cannula into it. After the pouch had healed, he performed an anastomosis between the stomach and the duodenum thus making the gastric juice flow directly over the infrapapillary portion of the duodenum. The pH determinations of the blood plasma and of the duodenal secretions were made on alternating days. The animals were given daily hypodermic injections of histamine, 0.1 mg for each 15 Kg of body weight, for from six to eight weeks, at the end of which time the animals were killed. The author found typical ulcers in the infrapapillary portion of the duodenum below the anastomosis and none at the anastomosis. It appears that the mechanical damage to the mucosa from the use of clamps and suturing played a subordinate role in the causation of ulceration and that the ulcers found in the duodenal portion were due to the direct action of the histamine-stimulated gastric secretion introduced directly on the intestinal mucosa. The upper portion of the duodenum did not prove to be more resistant to the continued action of the gastric juice than other portions of the small intestine. In view of the fact that nervous influences, muscular spasms and circulatory disturbances could be definitely ruled out in these experiments, the damage to the mucous membranes must be ascribed to the peptic action of the gastric juice.

 *New Method of Roentgenoscopy in Pulmonary Diagnosis Roentgenography of Sections and Layers of Lung (Tomography) H Chaoul—p 700
 Deformities of Peripheral Diaphragm R Raspe—p 703
 *Etiology of Kohler's Disease of Navicular Bone of Foot J W Camerer—p 713

Roentgenography of Sections and Layers of the Lung—The new method described by Chaoul makes possible roentgenograms of sections and layers of any thickness desired and of structures at various depths, with the exclusion of portions located anteriorly and posteriorly. The advantage of this method becomes evident when it is considered that an ordinary roentgenogram is the product of the superposition of the shadows of all the structures that are within the cone of the rays. This summation of the shadows results in pictures the analysis of which is not only difficult but also misleading. The author illustrates this on a schematic sketch. He points out that the roentgenologic demonstration of sections of the body was first attempted by Bocage in 1921 and later by von Bartelink and Ziedes Des Plantes. However, the apparatus constructed by those investigators had shortcomings so that they were useless for practical purposes. Grossmann succeeded recently in constructing a tomographic instrument that proved suitable for practical work. The author improved the apparatus further so that the tomograph is now capable of producing roentgenograms of layers measuring from a few millimeters to 2 cm. in thickness. The instrument consists of a double-armed pendulum turnable on its horizontal axis to which are fastened the tube focus above and the film holder below. If the pendulum is swung from one point through the perpendicular central position to the other terminal point, the body layer located at the level of the axis of rotation is demonstrated as a sharply outlined picture, whereas all the structures located above and below become effaced. Thus the axis of rotation or the pendulum system needs only to be lifted or lowered in order to obtain pictures of higher or lower layers. The time required for making a tomogram varies from one to several seconds. The author reproduces and describes tomograms of a lung presenting productive fibrous tuberculosis, of a normal lung and of a lung showing fibrous cavernous tuberculosis.

Etiology of Kohler's Disease of Navicular Bone—Camerer observed Köhler's disease of the navicular bone of the foot and also disturbances in the ossification of the first cuneiform bone in two enzygotic triplets. The third triplet, although exposed to the same environmental influences, did not have this disorder. He differed from the other two triplets in several factors, so that the triplets may be considered as dizygotic. The author considers the fact that only the two enzygotic triplets developed Köhler's disease proof that genotypical factors are responsible for this disorder. He cites several reports from the literature that indicate the same etiology.

- *Development of Local Edema and Its Therapeutic Modification. C Ernst—p 599
 Further Studies on Power of Erythrocytes to Destroy Insulin F Rosenthal, Rie Friedheim and R Nagel—p 603
 *Chorea Minor and Avitaminosis F Widenbauer—p 608
 Familial Cholema C A A. Schrumph—p 612

Local Edema—Ernst states that he was able to demonstrate local edemas or an increased fluid content in the tissues of patients with vasoneurosis and of patients with red hypertension. He discusses the various factors that play a part in the development of local edemas such as changes in the capillary contents in the permeability of the capillary walls and in the structure and function of the tissues. That the capillaries of the two groups of patients have an increased permeability has been clearly demonstrated by cutaneous wheal tests which proved that the capillaries have an increased permeability for protein, and, since relatively small amounts of protein are capable of binding comparatively large amounts of water, this factor deserves especial consideration in local edemas. The author sug-

gests the possibility of a hereditary deficiency to explain the origin of the increased permeability. Moreover, the capillaries, particularly the venous ones, are dilated and dilatation is nearly always accompanied by increased permeability. The author thinks that endocrine, nervous and ionic factors play a part in the dilatation. However, the increased permeability alone is not a satisfactory explanation and it is possible that the tissue colloids also play a part. In this connection the author points out that in an acid milieu the cells have a tendency to retain greater amounts of water and that the simultaneous administration of acids increases the diuretic effect of salyrgan. To be sure, here too the mechanism is somewhat involved, for, according to Veil the diuresis is increased in greater acidity as well as in greater alkalinity. The author stresses the relation of the local edema to certain therapeutic measures, particularly venesection. He points out that venesection generally produces considerable improvement in patients with red hypertension. The author thinks that the favorable effect of venesection in patients with vasoneurosis or hypertension may be due to the fact that it effects a change in the abnormal constituents of the tissues. These patients frequently complain of fatigue, drawing pains in the back and in the extremities, vertigo, gastric disturbances and headaches. He points out that on the basis of his studies it appears probable that, as a result of the abnormal circulation, the tissues contain not only greater amounts of fluid, but also metabolic waste products, which result in the aforementioned symptoms. Venesection, by producing a sufficient difference in concentration between the tissue and the blood, makes an adequate discharge possible.

Chorea Minor and Avitaminosis—Widenbauer gives the history of a boy with chorea mollis who also had gastric achylia. He cites factors that suggest relations between chorea minor, spasmophilia, funicular myelitis and B avitaminosis. Yeast therapy was instituted because a deficiency in vitamin B was suspected. This treatment proved successful after other measures had failed. Subsequently the author resorted to treatment with yeast in three cases of chorea minor. These cases were likewise cured within a short period.

 Determination of Skin Temperature in Scatica E Eldblom—p 639
 *Cholesterol in Xanthomatosis L Nékam Jr and Berta Ottenstein—p 641

Cholesterol and Xanthomatosis—Nékam and Ottenstein relate the history of a woman, aged 53, who had on the trunk, particularly in the gluteal region and on the extensor surfaces of the upper extremities, numerous yellow papules, the size of lentils. The patient's skin likewise was slightly yellow, but the mucous membranes showed no icteric discoloration. Histologic examination of the papules disclosed a typical xanthomatous structure. The authors examined the blood of the patient for total fat content, total cholesterol content, cholesterol ester, free cholesterol, lecithin, and lipid phosphorus. The cholesterol and lecithin values were increased. The ratio between free cholesterol and ester cholesterol, which in the beginning was 1:6.5, was altered in the course of the treatment to 1:2, that is, it approached the normal ratio. Because there have been cases of xanthoma, in which the cholesterol was not increased, various theories have been advanced to explain the pathogenesis of xanthomatosis. Some stressed the importance of the lipid correlation, while others assumed that the impairment of the esterizing action of the liver was important. In the patient whose case is reported, the esters were increased, however and other functional tests of the liver disclosed normal conditions. In view of the hypercholesteremia, the authors considered the possibility of a deficient decomposition of the cholesterol and conducted a number of tests, which disclosed the absence of a functional disturbance in the decomposition of the cholesterol. They demonstrated that even under physiologic conditions there was no fermental cleavage of the cholesterol. However, they observed bacterial decomposition of cholesterol with a suspension of colon bacteria and with an extract obtained from the colon.

- Examinations in Acute Gastritis **E. Frohlich and I. Zwillinger**—p 616

Morphology and Function of Dome of Stomach—Heckmann shows that under normal conditions the dome of the stomach is in intimate contact with the left half of the diaphragm. If this is not the case, that is, if the distance of the upper aspect of the dome of the stomach from the upper aspect of the diaphragm is more than the combined thicknesses of the gastric wall and of the diaphragm it is an indication of a pathologic condition. This symptom appears in ascites, in carcinoma of the gastric dome or of the cardia, in perigastric adhesions in the region of the dome and in case of a displacement of the transverse colon above the stomach, between it and the dome of the diaphragm. The gastric dome has several functions, the most important of which is regulation of the internal pressure of the stomach, in that its size varies so that the total volume of the gastric contents becomes adjusted to the tonus determined internal space of the stomach, that is, the dome is small in case of high tonus of the gastric walls and large in case of low tension so that the necessary tonus is still attained. Phenomena such as persistent cructation and aerophagy occasionally may be compensatory mechanisms in other instances they are probably not the result of a primary change in the tonus but are of psychogenic origin. In the latter case they signify a functional disturbance of the stomach, which becomes manifest in sudden changes in the gastric pressure during the motor processes if the dome is too small, and in inadequate evacuation if the dome is too large.

Hypochloremic Azotemia in Surgical Patients—Franke and Litzner examined the behavior of the sodium chloride and the urea contents of the blood in forty patients who had been operated on. They found that the reduction in the sodium chloride and the increase in the urea (hypochloremic azotemia) are changes that take their course independently of each other but which frequently have a common origin. It is not so much the surgical wound surface that is the cause of this, but rather a hepatic disturbance, which in turn is the result of the primary disease or of the anesthesia. The hepatic disturbance causes changes in the mineral economy and in the nitrogen disintegration. In this connection the authors call attention to the advantages of local anesthesia compared to general anesthesia. They point out that, in cases with a considerable reduction in the sodium chloride content of the blood it is advisable to administer sufficient quantities of sodium chloride before or after the operation, although an oversupply of sodium chloride should be avoided, because it exerts an unfavorable influence on the healing process. Protective treatment of the liver is advisable, particularly if general anesthesia is employed.

Splenectomy in Leukemia—Popper relates the history of a man, aged 32, with intraperitoneal hemorrhage in myeloid leukemia. Splenectomy was done and was well tolerated by the patient. The blood picture improved at first, but when after several months, it again became unfavorable roentgen irradiation was instituted and improved the blood status again. The patient's general condition was good for about a year. Then leukemic swelling of the glands developed, but these, too improved under roentgen therapy. The patient died fifteen months after the splenectomy as the result of strangulation ileus. The author thinks that splenectomy should not be absolutely rejected in myeloid leukemia. He considers it justified in acute conditions, such as intraperitoneal hemorrhage, torsion of the spleen or infarcts and with preliminary roentgen irradiation also in other suitable cases.

Practical Application of Salt-Free Diet—According to Anton, a restriction in the use of water is of great importance in the preparation of salt-free food, for as a rule salt becomes necessary in proportion to the water content of the food. The generous use of raw vegetables is another great aid in salt-free diet. Moreover, the patient will require a certain time before he becomes accustomed to the salt-free diet. Meat can be made tasty without the use of salt by browning it quickly and adding only a little water. Natural condiments such as caraway, mustard, nutmeg, onions, cheese, butter and lemon can be used. Soups are improved in taste by the addition of vegetables, egg, cream and butter. Sweet, cold fruit soups may be served. Leafy vegetables should not be boiled in water. Potatoes should be boiled with their skins on, for then the lack of salt is not so noticeable. Root vegetables likewise should be boiled uncut and unpeeled. In preparing salads from raw leaves, care should be taken that the leaves are well dried after they are washed. If this is done vinegar, lemon or dressings prepared with them will give a good flavor without the aid of salt. If boiled vegetables are used for salads, they should be marinated for some time before serving. The taste of farinaceous foods is generally improved by the addition of cheese. A tasty salt substitute may be used in the water in which the farinaceous foods are boiled and also for seasoning at the table and in the preparation of some other foods.

Relation of Adrenal Cortex to Gonads—Reports in the literature as well as his own animal experiments and clinical observations convinced Thaddea that the hormones of the adrenal cortex play an important part in the regulation of carbohydrate metabolism. Experimental and clinical observations indicate that interrelations exist between the adrenal cortex and the gonads and between the anterior lobe of the hypophysis and the adrenal cortex. The hormone of the adrenal cortex influences the gonadal function apparently by way of the anterior lobe of the hypophysis. The author calls attention to the close biologic relation between vitamins and hormones particularly between the hormone of the adrenal cortex and vitamin C. Moreover, it cannot be doubted that vitamin C, just as the fat soluble vitamins, has correlations with the sexual sphere. The author considers the connection between Addison's disease and certain problems of pregnancy, namely, susceptibility to toxins, uterine contractions, pigment formation, sodium chloride exchange and adynamia. The organism's requirements for the hormone of the adrenal cortex are apparently considerably increased during pregnancy and there are indications of increased sensitivity to toxins during Addison's disease. In mild cases of Addison's disease it may be possible to carry the pregnancy to term, provided suitable hormone therapy is instituted. However, in severe cases interruption of the pregnancy is indicated. The uterine contractions are normal during Addison's disease. Pigmentation increases during pregnancy, in spite of treatment with the adrenal cortex extract. The symptoms most worthy of attention in the pregnant woman with Addison's disease are hyperemesis and adynamia. The sodium chloride content is usually reduced and since the hyperemesis reduces it still more, it is advisable to administer sodium chloride solution in addition to the usual dextrose-hormone therapy. The author sees the cause of the adynamia in a reduction of the glycogen, the lactic acid and the creatine phosphoric acid. Studies on the carbohydrate metabolism during Addison's disease and pregnancy indicate that it undergoes great changes in the hepatic and muscular chemistry which cannot be compensated by the administration of adrenal cortex extract. That deficiency in the hormone of the adrenal cortex produces severe structural changes in the gonads was observed in human subjects and was corroborated in animal experiments.
